- Pruritus is typically paroxysmal, worse at night, and may lead to scratching during sleep.
- Can be asymptomatic with patient scratching at night while asleep

PHYSICAL EXAM
- Well-circumscribed lichenified plaques with varying amounts of overlying excoriation or scaling
- Lichenification: accentuation of normal skin lines
- Hyperpigmentation or hypopigmentation can be seen.
- Scarring is uncommon with typical LSC; can be seen following ulcer formation or secondary infection
- Most commonly involves easily accessible areas
  - Lateral portions of lower legs/ankles
  - Nape of neck (lichen simplex nuchae)
  - Vulva/scrotum/anus
  - Extensor surfaces of forearms
  - Palmar wrist
  - Scalp

DIFFERENTIAL DIAGNOSIS
- Lichen sclerosis
- Psoriasis
- Atopic dermatitis
- Contact, irritant, or stasis dermatitis
- Extramammary Paget disease
- Lichen planus
- Mycosis fungoides
- Lichen amyloidosis
- Tinea
- Nummular eczema

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- No specific diagnostic test
- Microscopy (i.e., KOH prep) and culture preparation may be helpful in identifying possible bacterial or fungal infection.

Diagnostic Procedures/Other
- Skin biopsy if diagnosis is in question
- Patch testing may be used to rule out a contact dermatitis.

Test Interpretation
- Hyperkeratosis
- Acanthosis
- Lengthening of rete ridges
- Hyperplasia of all components of epidermis
- Mild to moderate lymphohistiocytic inflammatory infiltrate with prominent lichenification

TREATMENT

GENERAL MEASURES
- Patient education is critical.
- Low likelihood of resolution if patient unable to avoid scratching.
- Treatment aimed at reducing inflammation and pruritus.

MEDICATION

First Line
- Reducing inflammation
  - Topical steroids are first-line agents (1)[C].
  - High-potency steroids alone, such as 0.05% betamethasone dipropionate cream or 0.05% clobetasol propionate cream, can be used initially but should be avoided on the face, anogenital region, or intertriginous areas. They should be used on small areas only, for no longer than 2 weeks except under the close supervision of a physician.
  - Switch to intermediate- or low-potency steroids as response allows.
  - An intermediate-potency steroid, such as 0.1% triamcinolone cream, may be used for initial, brief treatment of the face and intertriginous areas, and for maintenance treatment of other areas.
  - A low-potency steroid, such as 1% hydrocortisone cream, should be used for maintenance treatment of the face and intertriginous areas.
  - Steroid tape, flurandrenolide, has optimized penetration and provides a barrier to continued scratching. Change tape once daily.
  - Intralesional steroids, such as triamcinolone acetate, are also safe and effective for severe cases.
- Preventing scratching
  - Topical antipruritic agents
  - 1st-generation oral antihistamines such as diphenhydramine and hydroxyzine for antipruritic and sedative effects
  - Sedating tricyclics, such as doxepin and amitriptyline, for nighttime itching
– Itching may occur at night while the patient is asleep; occlusive dressings may be helpful in these cases.

**ALERT**
High-dose and prolonged treatment with topical steroids can cause dermal/epidermal atrophy as well as pigmentary changes and should not be used on the face, intertriginous areas, or anogenital region. Duration of treatment on other parts of the body should not exceed 3 weeks without close physician supervision.

**Second Line**
All recommendations
- Topical aspirin has been shown to be helpful in treating neurodermatitis (2)[C].
- Topical 5% doxepin cream has significant antipruritic activity (2)[C].
- Topical capsaicin cream can be helpful for treatment of early disease manifestations (2)[C].
- 0.1% tacrolimus applied twice daily over 6 weeks as an effective alternative treatment (3)[C].
- Gabapentin was found to decrease symptoms in patients who are nonresponsive to steroids.
- Topical lidocaine can be effective in decreasing neuropathic pruritus (2)[C].
- Intradermal botulinum toxin injections have been reported to improve symptoms in patients with recalcitrant pruritus.
- Transcutaneous electrical nerve stimulation may relieve pruritus in patients for whom topical steroids were not effective (4)[C].
- A case report showed NB-UVB as a possible off-label treatment of refractory LSC (5)[C].
- SSRIs may be effective in controlling compulsive scratching secondary to psychiatric diagnosis.

**ISSUES FOR REFERRAL**
- No response to treatment
- Presence of signs and symptoms suggestive of a systemic cause of pruritus
- Consultation with a psychiatrist for patients with severe stress, anxiety, or compulsive scratching
- Consultation with an allergist for patients with multisystem atopic symptoms

**ADDITIONAL THERAPIES**
- Cooling of the skin with ice or cold compresses
- Soaks and lubricants to improve barrier layer function
- Occlusion of lesion with bandages or Unna boots
- Nail trimming
- Silk underwear to decrease friction in genital LSC

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Acupuncture has been shown as an effective treatment for pruritus (6)[C].
- Cognitive-behavioral therapy may improve awareness and help to identify coping strategies.
- Hypnosis may be beneficial in decreasing pruritus and preventing scratching.
- Homeopathic remedies (i.e., thuja and graphite) have been used.

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Patients should be followed for response to therapy, complications from therapy (especially topical steroids), and secondary infections.

DIET
Regular balanced diet

PATIENT EDUCATION
- Patients should understand the cause of this disease and the critical role they play in its resolution:
  - Emphasize that scratching and rubbing must stop for lesions to heal; medications ineffective if scratching continues
- Stress reduction techniques can be useful for patients for whom stress plays a role.
- Avoid exposure to known triggers.

PROGNOSIS
- Often chronic and recurrent
- Good prognosis if the itch–scratch cycle can be broken
- After healing, the skin should return to normal appearance but may also retain accentuated skin markings or post inflammatory pigmentary changes that may be slow to resolve.

COMPLICATIONS
- Secondary infection
- Scarring is rare without ulceration or secondary infection.
- Complications related to therapy, as mentioned in medication precautions
- Squamous cell carcinoma within affected regions is rare.

REFERENCES

ADDITIONAL READING

CODES

ICD10

L28.0 Lichen simplex chronicus

CLINICAL PEARLS

- LSC is a chronic inflammatory condition that results from repeated scratching and rubbing.
- Primary LSC originates de novo, whereas secondary LSC occurs in the setting of a preexisting pruritic dermatologic condition.
- LSC is a clinical diagnosis based on history and skin examination with biopsy only indicated in difficult or unclear cases.
- Stopping the itch–scratch cycle through patient education, skin lubrication, and topical medications is key.
• Treatment aimed at decreasing both inflammation and pruritus utilizing topical steroids and antipruritics
LONG QT INTERVAL
Henry DeYoung, MD  ●  Yousef Ahmed, MD  ●  Derek Lodico, DO

BASICS

DESCRIPTION

- QT interval: the measurement interval from the beginning of the QRS complex to the end of the T wave on the surface electrocardiogram (ECG). This represents the period from the onset of depolarization to completion of repolarization of the ventricular myocardium.
- Corrected QT interval (QTc): The QT interval has an inverse relationship with heart rate. The QTc is the QT interval corrected for heart rate. See formulas.
- Prolonged QTc is generally defined as >450 ms for adult males and >470 ms for adult females (1):
  - 430 to 450 ms considered borderline in men
  - 450 to 470 ms considered borderline in women (1,2,3)
  - 440 to 460 ms considered borderline in children ages 1 to 15 years old (4)
- Most cases of prolonged QT are acquired, but several genetic mutations cause inherited long QT syndrome (LQTS) (3).
- Prolonged QTc from any cause can precipitate polymorphic ventricular tachycardia (VT) called torsade de pointes (TdP), leading to dizziness, syncope, and sudden cardiac death from ventricular fibrillation (VF).

EPIDEMIOLOGY

Incidence
Incidence of medication-induced QTc prolongation and TdP varies with medication and a host of other factors. Exact incidences are difficult to estimate but may be 1:2,000 to 1:2,500 (2).

Prevalence

- Hereditary LQTS is estimated to occur in 1/2,500 to 1/7,000 births.
- Five thousand people across the United States may die yearly due to LQTS-related cardiac arrhythmia.

ETIOLOGY AND PATHOPHYSIOLOGY

- Acquired
  - Demographics: increasing age, female sex
  - Electrolyte abnormalities: hypokalemia, hypocalcemia, and hypomagnesemia
  - Noncardiac disease: hypothyroidism renal impairment, and hepatic impairment
  - Cardiac disease: heart failure, left ventricular hypertrophy (LVH), and myocardial ischemia (2)
  - Scenarios: rapid increase in the QT interval >60 ms, conversion from atrial fibrillation/bradycardia (5)
  - Medications (3)
    - Antiarrhythmic medications (quinidine, procainamide, dronedarone, dofetilide, sotalol, disopyramide, and amiodarone)
    - Antipsychotic medications: especially if given IV (haloperidol*, chlorpromazine*, thioridazine*, pimozide*)
Antidepressants: most commonly used drugs responsible (SSRIs, SNRIs, trazodone, TCAs)

Antibiotics/antivirals/antifungals/antiprotozoals/antimalarials: macrolides (clarithromycin*, erythromycin* also CYP3A4 inhibitors), fluoroquinolones, quinine, and chloroquine

Antiemetics: metoclopramide, ondansetron, promethazine

Opioids: methadone*, buprenorphine

Antihistamines: cetirizine, hydroxyzine, diphenhydramine

Decongestants: pseudoephedrine, phenylephrine

Stimulants: albuterol, phentermine

Misc: chloroquine*, pentamidine*, various antimuscarinics, and anticonvulsants

*Denote “high-risk” medication for TdP (2,5).

- Congenital
  - Loss of function mutations in several potassium ion membrane channels or gain of function mutations in the sodium or calcium ion membrane channels in cardiac myocytes (6)

- Pathophysiology
  - Depolarization (phase 0) of the myocardium results from the rapid influx of sodium through sodium channels (\(I_{Na}\)) causing myocyte contraction during systole; seen on ECG as the QRS complex
  - Repolarization occurs through the efflux of potassium from the cell (phases 2 and 3) by rapid (\(I_{Kr}\)) and slow (\(I_{Ks}\)) components of the delayed rectifier; represented by the T wave on an ECG.
  - Drug-induced QT prolongation most often due to blockade of the \(I_{Kr}\) channel leading to delay in phase 3 rapid repolarization (2).
  - In both cases, deviation from normal ion channel function leads to transmural dispersion of repolarization currents across the myocardium triggering early after depolarizations, which may devolve into TdP (3,6).
  - Prolonged QT interval alone does not denote imminent risk for TdP; TdP is often self-limited, but TdP can cause syncope or degrade to VF (2).

Genetics

- 13+ distinct genotypes are linked to LQTS (1,6).
- Penetrance is highly variable making both diagnosis and management challenging (3).
- LQT1 (40–55%) is the most common cause of LQTS. Loss of function in the KCNQ1 gene coding for the \(I_{Ks}\) transport protein; arrhythmias triggered by sympathetic activation (stress/exercise—especially swimming), leading to shorter ventricular repolarization
- LQT2 (30–45%) results from a mutation in the KCNH2 gene causing a defect in the \(I_{Kr}\) transport protein; at risk for cardiac events due to abrupt catecholamine surges like auditory stimuli/emotional arousal (postpartum)
- LQT3 (5–10%) is caused by a mutation in the SCN5A gene leading to a gain of function in the alpha subunit of the \(I_{Na}\) transport protein. Excessive sodium accumulates in the cell, increasing repolarization time. Prominent during sleep due to amplified inward flow of sodium at low heart rates (1,3,6).
- LQT4 to LQT13—<1% of the total frequency.
- Jervell and Lange-Nielsen syndrome (JLNS): autosomal recessive inheritance through homozygous or compound heterozygous mutations of the KCNQ1 or KCNE1 genes. Reduced
function in the $I_{Ks}$ transport protein; associated with sensorineural hearing loss

- Romano-Ward syndrome (RWS): most common. Results from any of the 13 identified gene mutations; autosomal dominant with variable penetrance and normal hearing
- Others: Andersen-Tawil syndrome (LQT7), Timothy syndrome (LQT8). Both are very rare (3,6).

**RISK FACTORS**
For the feared complication, TdP, risk factors include the following (2,5):

- Female (~2 times increased risk)
- QTc >500 ms (2 to 3 times increased risk)
- QTc >60 ms over previous baseline
- For every 10 ms increase in the QTc, there is a 5–7% increased risk for developing TdP.
- History of syncope or presyncope
- History of TdP
- Bradycardia
- Liver or kidney disease (by increasing blood levels of QT-prolonging medications)
- Medications that cause QTc prolongation
  - High doses
  - Fast infusions
  - Combination of medications
- Medications that inhibit CYP3A4
- Electrolyte abnormalities
  - Hypokalemia
  - Hypomagnesemia
  - Hypocalcemia
- For hereditary LQTS
  - Catecholamine surges from exercise, emotional stress, loud noises, postpartum

**GENERAL PREVENTION**

- Avoid (or use with caution) causative medications, including combinations with potentially additive effects (1)[C],(2)[C],(5)[C].
- Replete electrolytes (goal >2 mg, 4.5 to 5.0 K) (2)[C].
- Treat underlying diseases.
- Avoid strenuous sports in LQTS.
- Avoid sudden loud noises in LQTS (alarm clocks, doorbells, telephones).
- 36th Bethesda Conference recommends restriction of athletes from participation to class 1A activities (e.g., bowling, golf, riflery) although evidence of safe participation is emerging (3) [C].

**DIAGNOSIS**

**HISTORY**

- Incidental finding on ECG in asymptomatic patients
- Evaluate for syncope, presyncopal episodes, palpitations, and associated precipitating events (emotional triggers, swimming, diving).
- Family history of syncope or sudden cardiac death
History of seizures in patient or family members (tonic–clonic movement may be due to cerebral hypoperfusion during episodes of ventricular arrhythmia or syncope)

- Detailed medication history
- Congenital deafness

**PHYSICAL EXAM**
- The physical exam is typically unremarkable.
- Signs of underlying cardiac disease
- Signs of hypothyroidism, liver, or renal impairment
- Congenital deafness present in many forms of LQTS

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- ECG
- Metabolic panel: especially calcium, magnesium, and potassium
- TSH

**Follow-Up Tests & Special Considerations**
- Echocardiogram to evaluate for cardiomyopathy
- Outpatient cardiac rhythm monitoring
- Consider provocative testing (epinephrine infusion, exercise stress testing) to evaluate for QTc interval changes and/or for coronary artery disease (2)[C].
- Genetic testing for LQTS mutations

**Test Interpretation**
- The QT interval is best measured from the onset of the QRS to the completion of the T wave; most commonly measured in lead II or V2
- QTc calculation can be performed in several ways using RR interval immediately preceding the QT interval for calculation. The Bazett formula is most commonly used method (1,2).
  - Framingham formula: QT + 0.154 (1 − RR)
  - Bazett formula: QTc = QT / √(RR) (all measurements in seconds, and RR obtained by direct measurement or 60/heart rate)
  - Fridericia formula is similar to Bazett but uses the cube root RR interval. QTc = QT / (RR)¹/³

**TREATMENT**

**GENERAL MEASURES**
- Treat VT, TdP, and VF emergently per advanced cardiovascular life support (ACLS) guidelines.
- Withdraw offending agents and correct electrolytes (2)[C].
- Transvenous cardiac pacing or isoproterenol may be used for drug-induced TdP to prevent bradycardia. Maintain heart rate 90 to 110 beats/min.

**MEDICATION**

First Line
For TdP: magnesium sulfate 2 g infused over 2 to 5 minutes, followed by continuous infusion of 2 to 4 mg/min if needed. Flushing is a normal side effect of bolus injections. Monitor for magnesium toxicity in those with renal insufficiency (1)[C],(2)[C].

For hereditary LQTS, to prevent life-threatening arrhythmias: propranolol or nadolol generally regarded as the best β-blockers for management of LQTS, although rigorous studies are lacking (7)[B].

β-Blockers are effective in decreasing but not eliminating the risk of fatal arrhythmias.

For high-risk patients who remain symptomatic on a β-blocker, implantable cardiac defibrillators (ICDs) with or without pacemaker may be indicated (2)[B],(6)[B].

**Second Line**

Atenolol or metoprolol may be used, although switching β-blockers may precipitate lethal or near-lethal events (7)[B].

**ISSUES FOR REFERRAL**

- Refer to cardiologist to establish diagnosis, especially for hereditary LQTS.
- Symptomatic prolonged QT

**SURGERY/OTHER PROCEDURES**

- ICD for those with a history of major cardiac events
- Left cervical-thoracic sympathetic denervation was used for symptomatic LQTS prior to the advent of β-blockers. It is still an option for those patients with LQTS who are refractory to β-blocker therapy (3)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Treat TdP, VT, and VF promptly as per ACLS guidelines. Correct electrolytes on an emergent basis. Evaluate for acquired QT prolongation. If no cause is found, consider hereditary LQTS.
- Patients with prolonged QTc and syncope/near syncope should be monitored on telemetry.
- Obtain a baseline ECG if initiating or combining medications with QT-prolonging medications, then when the drug reaches steady state, at 30 days, and annually thereafter.
- Avoid QT-prolonging medications in patients with congenital LQTS.
- Patients at risk of LQTS should be educated on symptoms of arrhythmia.
- Monitor electrolytes, urgently treat hypomagnesemia and hypokalemia, and discontinue/change offending medications (1)[C],(2)[C]
- Avoid sudden loud noises or emotional stress for those who have LQTS.
- Review adherence to β-blocker therapy.
- Clinical decision support systems may be useful to assess the risk of drug-induced risk of QT prolongation while considering clinical scenario (5).
- Notify others if telemetry monitoring reveals prolonged QT interval.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

On routine visits, ask about syncope, presyncope, and palpitations in those who have QTc prolongation.
- Consider ECG and/or outpatient cardiac rhythm monitoring with medication additions or dosage changes.
Prompt evaluation is warranted for symptomatic QTc prolongation of any cause. 
Check and correct for electrolyte imbalances.

PATIENT EDUCATION
- Educate patients with QTc prolongation about medications’ side effects and medication interactions.
- Patients with congenital forms of LQTS should be aware of and avoid triggers (depending on their specific gene mutation).
- Consider the emotional and psychological impacts. Additional reading by Fortescue shares personal impact of LQTS.
- Information and support from groups listed may be helpful (see “Additional Reading”).

PROGNOSIS
Acquired LQTS will resolve after withdrawal of offending agents and normalization of metabolic abnormalities. Patients with underlying cardiovascular disease may be at increased risk of mortality and require further intervention. Prognosis for congenital LQTS if untreated is quite poor. Perhaps 20% of untreated patients presenting with syncope die within 1 year, 50% within 10 years (4,6).

CODES

ICD10

I45.81 Long QT syndrome

CLINICAL PEARLS

- Evaluate for acquired causes before making a diagnosis of hereditary LQTS.
- For accurate diagnosis, calculate QTc manually.
- The ideal management of TdP is prevention; avoid multiple “stacking” risk factors and seek alternates to high-risk medications, correct electrolytes, and monitor treatment with serial ECGs if no alternatives exist.
- Magnesium sulfate is the treatment of choice during ACLS for TdP.
- β-Blockers are initial treatment of choice for hereditary LQTS.
LUNG, PRIMARY MALIGNANCIES
Zeeshan Mirza, MD ● Mohammad A. Razaq, MD

BASICS

DESCRIPTION

- Primary lung cancers are the leading cause of cancer-related deaths in the United States (estimated 154,050 deaths in 2018, 25.3% of all cancer-related deaths).
- Divided into two broad categories
  - Non–small cell lung cancer (NSCLC) (>85% of all lung cancers); normally originate in periphery
    - Adenocarcinoma (~40% of NSCLC): most common type in the United States and also nonsmokers; metastasizes earlier than squamous cell; lepidic growth, a subtype of adenocarcinoma has better prognosis.
    - Squamous cell carcinoma (SCC) (also known as epidermoid carcinoma) (~25% of NSCLC): dose-related effect with smoking; slower growing than adenocarcinoma
    - Large cell (~10% of NSCLC): prognosis similar to adenocarcinoma
  - Small cell lung cancer (SCLC) (16% of all lung cancers): centrally located, early metastases, aggressive
- Others: mesothelioma and carcinoid tumor

Staging

- Both NSCLC and SCLC: staged from I to IV based on: primary tumor (T), lymph node status (N), and presence of metastasis (M)
- SCLC further staged by:
  - Limited disease: confined to ipsilateral hemithorax
  - Extensive disease: beyond ipsilateral hemithorax (stages IIIB and IV), which may include malignant pleural or pericardial effusion or hematogenous metastases (stage IV)
  - Tumor locations: upper: 60%; lower: 30%; middle: 5%; overlapping and main stem: 5%
  - May spread by local extension to chest wall, diaphragm, pulmonary vessels, vena cava, phrenic nerve, esophagus, or pericardium
  - Most commonly metastasize to lymph nodes (pulmonary, mediastinal), then liver, adrenal glands, bones, brain

EPIDEMIOLOGY

Incidence

- Estimated 234,030 new cases in the United States in 2018
- Usual age of diagnosis: between 65 and 74 years; peak at 70 years
- Predominant sex: male > female

Prevalence

- Most common cancer worldwide
- Lifetime probability: men: 1 in 15; women: 1 in 17

ETIOLOGY AND PATHOPHYSIOLOGY

Multifactorial; see “Risk Factors.”
Genetics
NSCLC
- Oncogenes: Ras family (H-ras, K-ras, N-ras)
- Tumor suppressor genes: retinoblastoma, p53

RISK FACTORS
- Smoking
- Secondhand smoke exposure
- Radon
- Environmental and occupational exposures
  - Asbestos exposure (synergistic increase in risk for smokers)
  - Air pollution
  - Ionizing radiation
  - Mutagenic gases (halogen ethers, mustard gas, aromatic hydrocarbons)
  - Metals (inorganic arsenic, chromium, nickel)
- Lung scarring from tuberculosis
- Radiation therapy to the breast or chest

GENERAL PREVENTION
- Smoking cessation and prevention programs
- Screening recommended by NCCN and shown to reduce mortality in National Lung Screening Trial (NLST) (1)[A]
  - Annual screening recommended with low-dose computed tomography (CT) in adults aged 55 to 74 years who have a 30 pack-year smoking history and currently smoke or have quit within the past 15 years
  - Screening should be discontinued once a person has not smoked for 15 years or develops a health problem that substantially limits life expectancy or the ability or willingness to have curative lung surgery.
  - Prevention via aggressive smoking cessation counseling and therapy; a 20–30% risk reduction occurs within 5 years of cessation.
  - Avoid hormone replacement therapy in postmenopausal smokers or former smokers (increased risk of death from NSCLC).

COMMONLY ASSOCIATED CONDITIONS
- Paraneoplastic syndromes: hypertrophic pulmonary osteoarthropathy, Lambert-Eaton syndrome, Cushing syndrome, hypercalcemia from ectopic parathyroid-releasing hormone, syndrome of inappropriate antidiuretic hormone (SIADH)
- Hypercoagulable state
- Pancoast syndrome
- Superior vena cava syndrome
- Pleural effusion
- Chronic obstructive pulmonary disease (COPD), other sequelae of cigarette smoking

DIAGNOSIS
HISTORY
• May be asymptomatic for most of course
• Respiratory
  – Cough (new or change in chronic cough)
  – Wheezing and stridor
  – Dyspnea
  – Hemoptysis
  – Pneumonitis (fever and productive cough)
• Constitutional
  – Malaise
  – Bone pain (metastatic disease)
  – Fatigue
  – Weight loss, anorexia
  – Fever
  – Anemia
• Other presentations
  – Chest pain (dull, pleuritic)
  – Shoulder/arm pain (Pancoast tumors)
  – Dysphagia
  – Plethora (redness of face or neck)
  – Hoarseness (involvement of recurrent laryngeal nerve)
  – Horner syndrome
  – Neurologic abnormalities (e.g., headaches, syncope, weakness, cognitive impairment)
  – Pericardial tamponade (pericardial invasion)

**PHYSICAL EXAM**
• General: fever, chills, night sweats, weight loss
• Head, eye, ear, nose, throat (HEENT): Horner syndrome, dysphonia, stridor, scleral icterus, dysphagia
• Neck: supraclavicular/cervical lymph nodes, mass
• Lungs: effusion, wheezing, airway obstruction, dyspnea
• Abdomen/groin: hepatomegaly or lymphadenopathy
• Extremities: signs of hypertrophic pulmonary osteoarthropathy, deep venous thrombosis (DVT), fingernail clubbing
• Neurologic: headache, syncope, weakness, cognitive impairment

**DIFFERENTIAL DIAGNOSIS**
• COPD (may coexist)
• Granulomatous (tuberculosis, sarcoidosis)
• Cardiomyopathy
• Congestive heart failure (CHF)

**DIAGNOSTIC TESTS & INTERPRETATION**

Initial Tests (lab, imaging)
• Serum
  – CBC
  – Comprehensive metabolic panel (CMP)
  – Hypercalcemia (paraneoplastic syndrome)
– Hyponatremia (SIADH)
– Lactate dehydrogenase (LDH)

● Sputum cytology
● Chest x-ray (CXR) (compare with prior XRs)
  – Nodule or mass, especially if calcified
  – Persistent infiltrate
  – Atelectasis
  – Mediastinal widening
  – Hilar enlargement
  – Pleural effusion
● CT scan of chest (with IV contrast)
  – Nodule or mass (central or peripheral)
  – Lymphadenopathy
● Evaluation for metastatic disease
  – Positron emission tomography (PET) scan to evaluate metastasis mediastinal lymphadenopathy (replacing CT abdomen/pelvis and bone scan)
  – Brain MRI: Lesions may be necrotic, bleeding.

Follow-Up Tests & Special Considerations
CBC, BUN, serum creatinine, LFTs prior to each cycle of chemotherapy

Diagnostic Procedures/Other
● Biopsy with pathology review using
  – Bronchoscopy with transbronchial biopsy (WANG needle)
  – CT-guided biopsy of lung mass or metastatic site
  – Endobronchial ultrasound (EBUS)-guided fine-needle aspiration
  – Enlarged mediastinal lymph nodes necessitate staging by mediastinoscopy, video-assisted thoracoscopy, EBUS-guided fine-needle aspiration.
● Video-assisted thoracoscopy (associated pleural disease and suspected mediastinal nodal spread)
● Pulmonary function tests
● In patients with advanced NSCLC, determination of epidermal growth factor receptor (EGFR)-activating mutations, BRAF mutation, KRAS/NRAS mutations, ALK gene rearrangements, and ROS1 fusions in patients with non-SCC (NSCC) or mixed squamous histology
● PD-L1 testing
● Bone marrow aspirate (small cell)

Test Interpretation
Pathologic changes from smoking are progressive: basal cell proliferation, development of atypical nuclei, stratification, metaplasia of squamous cells, carcinoma in situ, and then invasive disease.

🚀 TREATMENT

GENERAL MEASURES
● NSCLC
  – Stage I, stage II, and selected stage III tumors are surgically resectable. Neoadjuvant or
adjuvant therapy is recommended for many patients with high risk IB, II, and IIA NSCLC. Patients with resectable disease who are not surgical candidates may receive radiation therapy.

- Patients with unresectable or N2, N3 disease are treated with concurrent chemoradiation. Selected patients with T3 or N2 disease can be treated effectively with surgical resection and either pre- or postoperative chemotherapy or chemoradiation therapy.
- Patients with distant metastases (M1B) can be treated with chemotherapy, targeted therapy, immunotherapy, or radiation therapy for palliation or best supportive care alone.

- **SCLC**
  - Limited stage: concurrent chemoradiation
  - Extensive stage: combination chemotherapy
  - Consider prophylactic cranial irradiation (PCI) in patients achieving a complete or partial response (2)[A].

- Quality-of-life assessments: Karnofsky Performance Status (KPS) scale (http://www.hospicepatients.org/karnofsky.html); Eastern Cooperative Oncology Group (ECOG)
- Discussions with patient and family about end-of-life care

### MEDICATION
- Chemotherapies, targeted therapies, and immunotherapies are the mainstay of treatment.
- Adjuvant chemotherapy following surgery improves survival in patients with fully resected stages II and III NSCLC.
- Palliative measures: analgesics
- Dyspnea: oxygen, morphine

### First Line
- **NSCLC**
  - Stages II and III: neoadjuvant or adjuvant chemotherapy
    - Cisplatin-based doublets (combination with paclitaxel, etoposide, vinorelbine, docetaxel, gemcitabine)
    - Carboplatin alternative for patients unlikely to tolerate cisplatin
    - Cisplatin plus pemetrexed (NSCC)
  - Unresectable stages IIA, IIIB
    - Concurrent chemoradiation
      - Cisplatin plus etoposide, vinblastine, or pemetrexed (NSCC) plus concurrent radiation
      - Carboplatin plus paclitaxel plus concurrent radiation
      - Carboplatin plus pemetrexed (NSCC) plus concurrent radiation

- **Stage IV**
  - No chemotherapy regimen can be recommended for routine use.
  - Cisplatin- or carboplatin-based doublets
    - +/− Bevacizumab (NSCC)
    - Erlotinib, afatinib, gefitinib, or osimertinib for patients with EGFR mutations
    - Dabrafenib with trametinib for untreated patients with BRAF V600E mutations
    - Pembrolizumab with pemetrexed and carboplatin for NSCC regardless of PD-L1 expression
    - Pembrolizumab monotherapy for NSCLC with PD-L1 expression ≥50% of tumor cells
    - Alectinib, dacomitinib for untreated ALK-positive NSCLC
    - Crizotinib for patients with EML4-ALK translocations or ROS1-positive NSCLC
Ceritinib, brigatinib for patients who fail or are intolerant to crizotinib
- Maintenance therapy after 4 to 6 cycles in patients achieving a response or stable disease
- Continuation of bevacizumab, pemetrexed (NSCC), gemcitabine or pembrolizumab or switch to pemetrexed (NSCC), erlotinib (EGFR mutations), docetaxel or observation

**SCLC**
- Cisplatin or carboplatin plus etoposide

**Second Line**

**NSCLC**
- Cisplatin-based doublets +/- bevacizumab (NSCC) if not previously used
- Docetaxel, pemetrexed (NSCC), erlotinib, gemcitabine, ramucirumab plus docetaxel, or nivolumab (squamous cell)
- Atezolizumab if progressed during or after first-line platinum-based drug
- Brigatinib or alectinib, ceritinib for ALK-positive patients who failed crizotinib

**SCLC**
- Topotecan or CAV (cyclophosphamide, doxorubicin, vincristine), gemcitabine, docetaxel, paclitaxel, nivolumab

**ADDITIONAL THERAPIES**
- Smoking cessation counseling
- Consider IV bisphosphonates or denosumab in patients with bone metastases to reduce skeletal-related events.

**SURGERY/OTHER PROCEDURES**
- Resection for NSCLC, for stages I, II, and IIIA, if medically fit to undergo surgery
- Resection of isolated, distant metastases has been achieved and may improve survival.
- Resection involves lobectomy in 71%, wedge in 16%, and complete pneumonectomy in 18%.
- Resection should be accompanied by lymph node dissection for pathologic staging.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Depends on clinical history; in general, postoperative visits every 3 to 6 months in the first 2 years after surgery with physical exam and CT scan
- Follow-up usually lifelong with CT scans, following NCCN criteria

**PATIENT EDUCATION**
- National Cancer Institute: [https://www.cancer.gov/](https://www.cancer.gov/)
- Smokefree.gov: [https://smokefree.gov/](https://smokefree.gov/)

**PROGNOSIS**
- For combined, all types and stages, 5-year survival rate is 18.6%.
- NSCLC 5-year survival
  - Localized disease: for stages IA1, IA2, and IA3 is 92%, 83%, and 77%, respectively; stages IB and IIA is 68% and 60%, respectively
  - Regional disease: for stages IIIA, IIIB, and IIIC is 36%, 26%, and 13%, respectively
- Distant metastatic disease: for stages IVA and IVB is 10% and <1%, respectively
- SCLC
  - Without treatment: median survival from diagnosis of only 2 to 4 months
  - 5-year survival rate: ranges from 2% (stage IV) to 31% (stage I)
  - Extensive-stage disease: median survival of 6 to 12 months; long-term disease-free survival is rare.

**COMPLICATIONS**
- Development of metastatic disease
- Local recurrence of disease
- Postoperative complications
- Side effects of chemotherapy or radiation

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- C34.90 Malignant neoplasm of unsp part of unsp bronchus or lung
- C34.10 Malignant neoplasm of upper lobe, unsp bronchus or lung
- C34.30 Malignant neoplasm of lower lobe, unsp bronchus or lung

**CLINICAL PEARLS**
- Two types: NSCLC and SCLC
  - NSCLC (>85% of all lung cancers); normally originate in periphery
    - Adenocarcinoma (~40% of NSCLC)
    - SCC (~25% of NSCLC)
    - Large cell (~10% of NSCLC)
  - SCLC centrally located, early metastases, aggressive
- Prognosis and treatment of lung cancer differ greatly between small cell and non–small cell histologies.
- Adjuvant cisplatin-based chemotherapy improves survival in patients with completely resected stages II and III NSCLC.
Chemotherapy, with or without radiation, can be offered to patients with advanced NSCLC or SCLC.

There is little role for surgery in the treatment of SCLC.
LUPUS ERYTHEMATOSUS, SYSTEMIC (SLE)
Katherine M. Tromp, PharmD ● Hershey S. Bell, MD, MS, FAAFP

BASICS
DESCRIPTION
- Systemic lupus erythematosus (SLE) is a multisystem autoimmune inflammatory disease characterized by a chronic relapsing/remitting course; can be mild to severe and may be life-threatening (CNS and renal forms)
- System(s) affected: mucocutaneous; musculoskeletal; renal; nervous; pulmonary; cardiac; hematologic; vascular; gastrointestinal (GI)
- Synonym(s): SLE; lupus

ALERT
Women with SLE have a 7- to 50-fold increased risk of coronary artery disease and may present with atypical/nonspecific symptoms.

EPIDEMIOLOGY
Predominant age: 15 to 45 years

Incidence
- Per year, 1.6 to 7.6/100,000 and increasing due to better diagnosis
- Most common: African American women (8.1 to 11.4/100,000/year)
- Least common: Caucasian men (0.3 to 0.9/100,000/year)

Prevalence
Occurs in 30 to 50/100,000 and increasing due to increased survival

ETIOLOGY AND PATHOPHYSIOLOGY
- Skin: photosensitivity; scaly erythematous, plaques with follicular plugging, dermal atrophy, and scarring; nonscarring erythematous psoriasiform/annular rash; alopecia; mucosal ulcers
- Musculoskeletal: nonerosive arthritis; ligament and tendon laxity, ulnar deviation, and swan neck deformities; avascular necrosis
- Renal: glomerulonephritis
- Pulmonary: pleuritis, pleural effusion, alveolar hemorrhage, pneumonitis, interstitial fibrosis, pulmonary hypertension, pulmonary embolism (PE)
- Cardiac: nonbacterial verrucous endocarditis, pericarditis, myocarditis, atherosclerosis
- CNS: thrombosis of small intracranial vessels ± perivascular inflammation resulting in micro- or macroinfarcts ± hemorrhage
- Peripheral nervous system: mononeuritis multiplex, peripheral neuropathy
- GI: pancreatitis, peritonitis, colitis
- Hematologic: hemolytic anemia, thrombocytopenia, leukopenia, lymphopenia
- Vascular: vasculitis, thromboembolism
- Most cases are idiopathic with possible environmental factors.
- Drug-induced lupus: hydralazine, D penicillamine, quinidine, procainamide, minocycline, isoniazid, etc.
**Genetics**
- Identical twins: 24–58% concordance
- Fraternal twins and siblings: 2–5% concordance
- 8-fold risk if first-degree relative with SLE
- Major histocompatibility complex associations: HLA-DR2, HLA-DR3
- Deficiency of early complement components, especially C1q, C1r/s, C2, and C4
- Immunoglobulin receptor polymorphisms: FCγR2A, FCγR3A, and others
- Polymorphism in genes associated with regulation of programmed cell death, protein tyrosine kinases, and interferon production

**RISK FACTORS**
- Race: African Americans, Hispanics, Asians, and Native Americans
- Predominant sex: females > males (10:1)
- Environmental: UV light, infectious agents, stress, diet, drugs, hormones, vitamin D deficiency, and tobacco

**COMMONLY ASSOCIATED CONDITIONS**
- Overlap syndromes: rheumatoid arthritis (RA), Sjögren syndrome, scleroderma
- Antiphospholipid syndrome; coronary artery disease; nephritis; depression

**DIAGNOSIS**
Consider SLE in multisystem disease including fever, fatigue, and signs of inflammation.

**HISTORY**
- Fever, fatigue, malaise, weight loss, headache
- Rash (discoid [LR+] = 18, malar [LR+] = 14), photosensitivity (LR+) = 11, alopecia
- Oral/nasal ulcers (usually painless)
- Arthritis, arthralgia, myalgia, weakness
- Pleuritic chest pain, cough, dyspnea, hemoptysis
- Early stroke (age <50 years), unexplained seizure/psychosis (LR+) = 13, cognitive deficits
- Proteinuria, cellular casts
- Hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia
- Abdominal pain, anorexia, nausea, vomiting
- Raynaud phenomenon

**PHYSICAL EXAM**
- Vital signs: fever, hypertension
- Malar, discoid, psoriasiform, or annular rash, alopecia
- Oral/nasal ulcers (often minimally symptomatic)
- Lymphadenopathy, splenomegaly
- Acrocyanosis
- Inflammatory arthritis, tenosynovitis
- Pleural/pericardial rub, heart murmur
- Bibasilar rales
- Cranial/peripheral neuropathies
DIFFERENTIAL DIAGNOSIS
Undifferentiated connective tissue disease, Sjögren syndrome, fibromyalgia, RA, vasculitis, idiopathic thrombocytopenia purpura, antiphospholipid antibody syndrome, drug-induced lupus

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
American College of Rheumatology (ACR) and Systemic Lupus International Collaborating Clinics (SLICC) criteria
- ACR and the SLICC have established diagnostic criteria for SLE.
- ACR requires at least 4 of 11 criteria be met (95% specificity; 85% sensitivity).
- SLICC requires at least 4 of 13 criteria including at least 1 abnormal clinical criterion and 1 abnormal immunologic criterion or patient must have biopsy—confirmed lupus nephritis and elevated ANA or anti-dsDNA levels (97% specificity; 84% sensitivity).
- ACR remains the gold standard; SLICC not yet endorsed by ACR
  - Cardiac/pulmonary: ACR: pleuritic or pericarditis; SLICC: serositis
  - Hematologic: ACR: hemolytic anemia or leukopenia or lymphopenia or thrombocytopenia; SLICC: hemolytic anemia, leukopenia or lymphopenia more than once, thrombocytopenia
  - Immunologic: ACR: positive antinuclear antibody (ANA), elevated anti double-stranded DNA (anti-dsDNA), anti-Smith (anti-Sm) or antiphospholipid antibodies; SLICC: positive ANA, elevated anti-dsDNA, anti-Sm, or phospholipid antibodies, low complement (C3, C4, CH50) or direct Coombs test (in absence of hemolytic anemia), chronic cutaneous lupus, nonscarring alopecia, oral or nasal ulcers
  - Musculoskeletal: ACR: nonerosive arthritis involving two or more joints; SLICC: synovitis involving two or more joints, or tenderness at two or more joints and at least 30 minutes of morning stiffness
  - Neuropsychiatric: ACR: seizure or psychosis; SLICC: seizures, psychosis, mononeuritis complex, myelitis, or peripheral or cranial neuropa thy
  - Renal: ACR: persistent proteinuria >0.5 g per day or >3+ on urine dipstick, or cellular casts; SLICC: urinary creatinine (or 24-hour urinary protein) >500 mg or red blood cell casts
  - Skin/mucosal: ACR: malar rash; SLICC: acute or subacute cutaneous lupus
- Initial imaging is dependent on presenting symptoms.
  - Radiograph of involved joints
  - Chest x-ray: infiltrates, pleural effusion, low lung volumes
  - Chest CT scan, ventilation/perfusion (V/Q) scan, duplex ultrasound for PE or deep vein thrombosis
  - Head CT scan: ischemia, infarct, hemorrhage
  - Brain MRI: focal areas of increased signal intensity
  - Echocardiogram: pericardial effusion, valvular vegetations, pulmonary hypertension
  - Contrast angiography for medium-size artery vasculitis: mesenteric/limb ischemia, CNS symptom

Follow-Up Tests & Special Considerations
- Hemolytic anemia: elevated reticulocyte count and indirect bilirubin, low haptoglobin, positive direct Coombs test
- Confirm positive phospholipid antibodies results in 12 weeks.
- If phospholipid antibodies are initially negative, but symptoms arise, repeat because they may become positive over time.
- 24-hour urine collection/spot protein/creatinine to quantify proteinuria
- Histone antibodies present in >95% of drug-induced lupus (vs. 80% of idiopathic SLE)
- Fasting lipid panel and glucose
- Follow vitamin D(25[OH]) levels and replenish PRN.

**Diagnostic Procedures/Other**
- Renal biopsy to diagnose lupus nephritis (if UA abnormal)
- Skin biopsy with immunofluorescence on involved and uninvolved non–sun-exposed skin (lupus band test) may help differentiate SLE rash from others.
- Lumbar puncture in patients with fever and CNS/meningeal symptoms
- EEG for seizures/global CNS dysfunction
- Neuropsychiatric testing for cognitive impairment
- EMG/nerve conduction study (NCS) for peripheral neuropathy and myositis
- Nerve and/or muscle biopsy
- ECG, cardiac enzymes, stress tests

**Test Interpretation**
- Skin: vascular/perivascular inflammation, immune-complex deposition at dermal–epidermal junction, mucinosis, basal layer vacuolar changes
  - Similar findings seen in other connective tissue disorders such as dermatomyositis
- Renal: mesangial hypercellularity/matrix expansion, subendothelial/subepithelial immune deposits, glomerular sclerosis, fibrous crescents
  - Vary depending on degree of involvement
- Vascular: immune-complex deposition in vessel walls with fibrinoid necrosis and perivascular mononuclear cell infiltrates, intraluminal fibrin thrombi

**TREATMENT**

**GENERAL MEASURES**
- Education, counseling, and support
- Influenza/pneumococcal vaccines are safe; weigh risk versus benefit for live vaccines in immunocompromised patients.
- Low-estrogen oral contraceptives safe in mild SLE

**MEDICATION**

**First Line**
- Antimalarial agents and NSAIDs are first-line therapy for patients with mild SLE (1)[A].
  - Hydroxychloroquine for constitutional and musculoskeletal symptoms, rash, mild serositis; may reduce flares and increase long-term survival (1)[A],(2)[C]; recommended maximum dose is 5 mg/kg based on actual body weight (3)[C].
  - NSAIDs for musculoskeletal manifestations, mild serositis, headache, and fever (1)[A]
- Systemic glucocorticoids (prednisone or equivalent)
  - Low dose (<0.5 mg/kg) for minor disease activity not responsive to NSAIDs or when NSAIDs are contraindicated (1)[A]
  - High dose (1 to 2 mg/kg/day) (1)[A] or IV pulse methylprednisolone for organ-threatening disease, particularly CNS and renal; often combined with immunosuppressive agent (1)[A]
Topical corticosteroids for skin manifestations

Second Line
- Methotrexate (4)[C], azathioprine (4)[C], mycophenolate mofetil (4)[C], or leflunomide as steroid-sparing agent for persistent active disease or to maintain remission – Requires laboratory monitoring for toxicity
- Belimumab as adjunct for preventing flares in patients with active lupus despite first-line therapy (5)[B]
  - 10 mg/kg IV q2wk × 3 doses and then monthly
- Treatments under investigation: rituximab, epratuzumab, abatacept, interferon-α inhibitors
- Immunosuppressive agents for severe disease
  - Cyclophosphamide (1)[A]: adequate hydration to reduce risk of hemorrhagic cystitis
  - Mycophenolate mofetil (1)[A]: more efficacious for lupus nephritis (4)[A]

SURGERY/OTHER PROCEDURES
Renal transplant for end-stage renal disease

COMPLEMENTARY & ALTERNATIVE MEDICINE
Biofeedback, visual imagery, cognitive therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Difficult to differentiate SLE flare from infection; may need to treat both pending full evaluation
- IV pulse Solu-Medrol 1 g/day for 3 to 5 days for life- or organ-threatening disease (1)[A]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Clinical evaluation for signs and symptoms
  - Weekly to monthly for active disease
  - Every 3 to 6 months for mild/inactive disease
- Measures of disease activity and damage: Systemic Lupus Erythematosus Disease Activity Index, British Isles Lupus Assessment Group Index, European Consensus Lupus Activity Measure
- Laboratory studies
  - CBC with differential
  - Serum creatinine, UA
  - Vitamin D
  - Declining C3/C4 and rising dsDNA and ESR may correlate with disease activity.
- Monitor for adverse effects of treatment.
  - NSAIDs: GI bleeding and/or ulceration
  - Glucocorticoids: glucose, lipids, bone density
  - Hydroxychloroquine: ophthalmologic exam every 6 to 12 months
  - Methotrexate: CBC, creatinine, albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT) every 2 months
Azathioprine and mycophenolate mofetil: CBC every 1 to 3 months
Cyclophosphamide
  - CBC, creatinine, UA every 2 weeks, and liver function tests monthly during treatment
  - UA every 6 to 12 months for life

**DIET**
- No special diet unless for complications such as renal failure, diabetes, hyperlipidemia \((1)[A]\)
- Adequate calcium/vitamin D intake in patients on corticosteroids \((1)[A]\)
- Low glycemic index or calorie-restricted diet in patients on corticosteroids

**PATIENT EDUCATION**
- Avoid UV light exposure: sunscreens (SPF \(\geq 30\)), protective clothing \((1)[A]\).
- Weight control, smoking cessation, exercise \((1)[A]\)
- Stress avoidance/management

**PROGNOSIS**
- Permanent treatment-free remission is uncommon.
- 5-year survival after diagnosis is 95%.
- Poor prognostic factor: major organ involvement
- Drug-induced lupus resolves within weeks to months after discontinuation of the offending drug.

**COMPLICATIONS**
Infections, neoplasms, cardiac disease, nephritis, neuropsychiatric lupus; depression

**Pregnancy Considerations**
- Exacerbations during pregnancy are less common when in remission for 6 months prior to conception.
- Fetal loss is increased, especially in those with active lupus/antiphospholipid antibodies.
- A 2% risk of congenital heart block if anti–SS-A (Ro) or anti–SS-B (La) antibodies are present
- See “Antiphospholipid Antibody Syndrome” for recommendations regarding use of aspirin and heparin to prevent pregnancy complications.

**REFERENCES**

Antiphospholipid Antibody Syndrome

CODES

ICD10

- M32.9 Systemic lupus erythematosus, unspecified
- M32.10 Systemic lupus erythematosus, organ or system involv unsp
- M32.14 Glomerular disease in systemic lupus erythematosus

CLINICAL PEARLS

- Aggressiveness of therapy should reflect intensity of disease.
- Most important diagnostic test is the UA: if abnormal, order kidney biopsy; serum and urine lab values often do not reveal extent of kidney disease.
- Atherosclerotic and atheroembolic complications are the major cause of death; address modifiable cardiovascular risk factors.
LUPUS NEPHRITIS
Neena R. Gupta, MD

BASICS

DESCRIPTION
- The renal manifestation of systemic lupus erythematosus (SLE)
- American College of Rheumatology (ACR) criteria: persistent proteinuria >500 mg/day or ≥3 on dipstick and/or presence of cellular casts; alternatively, spot urine protein-to-creatinine ratio >0.5 and “active urinary sediment” (>5 red blood cell [RBC]/high-power field [HPF], >5 white blood cell [WBC]/HPF in absence of infection, or cellular casts—RBC or WBC casts) (1)
- Clinical manifestations primarily due to immune complex–mediated glomerular disease. Tubulointerstitial and vascular involvement often coexist. Diagnosis is based on clinical findings, urine abnormalities, autoantibodies, and renal biopsy.
- Treatment and prognosis depend on International Society of Nephrology/Renal Pathology Society (ISN/RPS) histologic class—risk of end-stage renal disease (ESRD) highest in class IV.
- Delay in diagnosis/treatment increases risk of ESRD. Early diagnosis improves renal outcomes.

EPIDEMIOLOGY
- Peak incidence of SLE is 15 to 45 years of age. Mean age of diagnosis is between 25 and 30 years of age.
- Predominant sex: female > male (10:1)
- Once SLE develops, lupus nephritis (LN) affects both genders equally; it is more severe in children and men and less severe in older adults.
- More common in African American and Asian populations.

Incidence
- SLE: 1.4 to 22/100,000
- Up to 60% of SLE patients develop LN over time; 25–50% of SLE patients have nephritis as the initial presentation.

Pediatric Considerations
LN is more common and more severe in children: 60–80% of children have LN at or soon after SLE onset.

Prevalence
SLE: 7.4 to 159.4/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Immune complex–mediated inflammation injures glomeruli, tubules, interstitium, and vasculature.
- Glomeruli: Varying degrees of mesangial proliferation, crescent formation, and fibrinoid necrosis cause reduced glomerular filtration rate (GFR).
Persistent inflammation (chronicity) leads to sclerosis and glomerular loss.
- Tubulointerstitial injury (edema, inflammatory cell infiltrate acutely; tubular atrophy in chronic phase) with or without tubular basement membrane immune complex deposition leads to reduced renal function.
- Vascular lesions: immune complex deposition and noninflammatory necrosis in arterioles
- SLE is a multifactorial disease, with multigenic inheritance; exact etiology remains unclear.
- Defective T-cell autoregulation and polyclonal B-cell hyperactivity contribute to dysregulated apoptosis. Impaired clearance of apoptotic cells inhibits self-tolerance to nuclear antigen.
- Anti-DNA, anti-C1q, anti-α-actin, and other nuclear component autoantibodies develop.
- Deposition of circulating immune complexes or autoantibodies attaching to local nuclear antigens leads to complement activation, inflammation, and tissue injury.
- Interaction of genetic, hormonal, and environmental factors leads to great variability in LN severity.

Genetics
- Polygenic inheritance; clustering in families, ~25% concordance in identical twins
- Interaction of general SLE susceptibility genes with more renal-specific genes and epigenetic changes

RISK FACTORS
Younger age, African American or Hispanic race, more ACR criteria for SLE, longer disease duration, hypertension, lower socioeconomic status, family history of SLE, anti-dsDNA antibodies, low albumin to globulin ratio

COMMONLY ASSOCIATED CONDITIONS
Skin, hematologic, cerebral, pulmonary, GI, and cardiopulmonary systems are often involved in SLE.

DIAGNOSIS

HISTORY
- Assess for risk factors and other signs/symptoms of SLE: rash, photosensitivity, arthritis, neurologic complaints, fever, weight loss, alopecia.
- Active nephritis is often accompanied by fever, peripheral edema, nausea, vomiting, headache, and dizziness.

PHYSICAL EXAM
- Hypertension, fever
- Pleural/pericardial rub (serositis)
- Skin rash
- Edema
- Arthritis
- Alopecia
- Oral ulcers
- Signs of synovitis (joint tenderness, warmth, swelling)

DIFFERENTIAL DIAGNOSIS
Primary glomerular disease
Secondary renal involvement in other systemic disorders such as antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, Henoch-Schönlein purpura (HSP), antiglomerular basement membrane disease, polyarteritis nodosa, and viral infections
Mixed connective tissue disorder may have glomerulonephritis indistinguishable from LN.

DIAGNOSTIC TESTS & INTERPRETATION
Renal biopsy is the gold standard for diagnosing and classifying LN.
Combine clinical data with serologic and renal biopsy patterns to differentiate LN from other conditions.
Active urine sediment suggests nephritis.
Autoantibodies, low C3, C4, and CH50 complement levels support LN diagnosis.

Initial Tests (lab, imaging)
Urinalysis may show hematuria, proteinuria, and active urine sediment.
Serum electrolytes, blood urea nitrogen, creatinine, albumin, routine serologic markers of SLE such as antinuclear antibody (ANA), anti-dsDNA, anti-La, anti-RNP, anti-Sm, antiphospholipid antibody, C3, C4, CH50, complete blood count (CBC) with differential, and C-reactive protein (CRP) (2)[C]
CBC may show anemia, thrombocytopenia, and leukopenia.
Renal ultrasound

Follow-Up Tests & Special Considerations
Monitor disease activity q3mo (2)[C]: urinalysis for hematuria and proteinuria; blood for C3, C4, anti-dsDNA, serum albumin, and creatinine.
Patients with estimated glomerular filtration rate (eGFR) of <60 mL should be managed according to the National Kidney Foundation guidelines for chronic kidney disease (CKD): https://kdigo.org/guidelines/ckd-evaluation-and-management/
Biomarker panel: alpha-1-acid glycoprotein (AGP); ceruloplasmin; lipocalin-like prostaglandin synthase (LPGDS); transferring correlates with disease activity in children.

Pregnancy Considerations
Pregnancy leads to worsening of renal function in LN. Risk factors include renal impairment at baseline, active disease, hypertension, and proteinuria.
Risk factors for fetal loss include elevated serum creatinine, heavy proteinuria, hypertension, and antiphospholipid antibodies.
Mycophenolate mofetil (MMF) is contraindicated in pregnancy; azathioprine can be used, U.S. Food and Drug Administration (FDA) pregnancy Category D.

Test Interpretation
Adequate renal biopsy (at least 10 glomeruli for light microscopy or total 20 to 25 glomeruli) is essential. Light, immunofluorescence, and electron microscopy are needed for accurate classification.
On immunofluorescence microscopy: Immune complex deposits consisting of IgG, IgA, IgM, C1q, and C3 (“full house”) are highly suggestive of LN.
Revised ISN/RPS histologic classification guides therapeutic decisions: https://www.kidneyinternational.org/article/S0085-2538(17)30859-1/fulltext
LN is classified as purely mesangial (class I—minimal mesangial LN and II—mesangial
proliferative LN), focal proliferative LN: <50% glomeruli (class III), diffuse proliferative LN: ≥50% (class IV), membranous LN (class V), and advanced sclerosis LN (class VI); subdivisions for activity (A) and chronicity (C) in class III/IV and for segmental (S) or global (G) glomerular involvement in class IV (class III A, C, A/C and class IV S[A], G[A], S[A/C], S[C], G[C])

- LN may change class over time or with therapy.
- Focal and diffuse proliferative LN (classes III and IV) are common and most likely to progress to ESRD.

## TREATMENT

The goal is to normalize renal function and prevent the progression of disease and/or loss of renal function.

### GENERAL MEASURES

- Monitor bone density; optimize vitamin D and calcium intake in patients on glucocorticoid therapy.
- Low-salt diet for hypertension and edema. For eGFR <60 mL: Follow National Kidney Foundation guidelines for CKD.
- Avoid sun or ultraviolet light exposure.

### MEDICATION

Note: Other than methylprednisolone and prednisone, no other medications listed below are FDA-approved for LN.

#### First Line

- Class I + II LN: No specific therapy is needed because long-term renal prognosis is good; renin-angiotensin system blockade (angiotensin-converting enzyme inhibitors or angiotensin receptor blockers) to manage BP and proteinuria (e.g., lisinopril 5 to 40 mg/day PO, losartan 25 to 100 mg/day PO)

| Proliferative LN (class III, IV, V + III/IV): Induce remission by steroids + IV cyclophosphamide or MMF and maintenance of remission by low-dose steroids and azathioprine or MMF (2,3)[A]. |

#### Principles of treatment:

- Avoid delay; induce remission quickly (3 to 6 months).
- Maintain response and avoid iatrogenic morbidity.

#### Induction: steroids + immunosuppressive agent (for mild class III, high-dose steroids may be sufficient):

- Glucocorticoids: methylprednisolone pulse 0.5 to 1.0 g/day for 3 days followed by oral prednisone 0.5 to 1.0 mg/kg/day PO (max 60 mg/day, taper after 4 to 8 weeks) (3,4,5)[A] and
- Cyclophosphamide: IV cyclophosphamide (high dose = 0.5 to 1.0 g/m² monthly for 6 doses—National Institutes of Health regimen; low dose = 0.5 g q2wk for 6 doses—Euro-Lupus regimen) or
- MMF: 1 to 3 g/day PO divided BID (target 3 g/day as tolerated) for 6 months. MMF is as effective as cyclophosphamide in achieving remission with fewer side effects (3,4,5)[A].

- Combination of tacrolimus and glucocorticoids has been found to have higher complete
remission than cyclophosphamide and glucocorticoids combination but no significant difference than MMF and glucocorticoids in Asian population. Combination of tacrolimus, MMF, and glucocorticoids showed higher complete remission than cyclophosphamide and glucocorticoids (6).

- **Maintenance:**
  - Glucocorticoids: oral prednisone tapered to low doses (generally <10 mg/day by 6 months) and
  - MMF 1 to 2 g/day divided BID PO OR azathioprine: 1.0 to 2.5 mg/kg/day PO (3,4,5)[A]
  - MMF shown to be equal to azathioprine for maintenance therapy in mostly Caucasian population.
  - Cyclophosphamide IV quarterly for 1 to 2 years after renal remission; not used now due to availability of less toxic regimen.
  - Optimum duration of maintenance therapy is unclear, but periods ranging from 3 to 10 years have been studied in clinical trials.

- **Class V LN:** good prognosis, no standardized treatment
  - For subnephrotic patients, no specific treatment except renin-angiotensin system blockade
  - Options for nephrotic patients include steroids with either calcineurin inhibitors, IV cyclophosphamide, azathioprine, or MMF (4,5)[A].
  - Class V LN with presence of class III or class IV biopsy findings needs aggressive combination regimen as for class III/IV.

**Second Line**
Refractory lupus nephritis: No response to initial treatment within 3–4 months. Change either cyclophosphamide to MMF or vice versa, rituximab, calcineurin inhibitors, stem cell transplantation, intravenous immunoglobulin, plasma exchange (7)[C]. Belimumab was approved by FDA in 2011, but trials excluded patients with severe, active LN.

**ISSUES FOR REFERRAL**
Nephrology consults for initial management and relapses

**ADDITIONAL THERAPIES**
- Kidney Disease: Improving Global Outcomes (KDIGO) guidelines for LN state that all patients with LN of any class be treated with background hydroxychloroquine (maximum daily dose of 6.0 to 6.5 mg/kg ideal body weight), unless they have a specific contraindication.
- BP control; treat dyslipidemia and other modifiable cardiovascular risk factors.
- Anticoagulation for symptomatic antiphospholipid antibody syndrome

**SURGERY/OTHER PROCEDURES**
- Renal transplant for ESRD when indicated
- Patient and graft survival rates similar to non-SLE patients
- Risk of recurrent LN in renal transplant recipients ranges between 0% and 30%; graft loss due to recurrence is rare.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization
  - Uncontrolled hypertension, acute kidney injury
  - Severe extrarenal manifestation
  - Control hypertension and proteinuria, if present.
- Labs to help confirm SLE/LN, renal ultrasound
- Nephrology input for management and renal biopsy
- Patients who have nephrotic syndrome or acute kidney injury should be fluid restricted.
- Once the patient is stabilized and renal biopsy is performed, manage safely as an outpatient.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Monitor urine protein-to-creatinine ratio, urine microscopy, serum albumin and creatinine, antibody titers (especially anti-dsDNA), C3, C4, BP at least every 3 months for first 2 to 3 years (2)[C].
- Once stable on maintenance therapy with no active disease, follow up every 6 to 12 months (2) [C].
- Cyclophosphamide: CBC; ensure adequate hydration.
- MMF: CBC, LFT, SrCr
- Azathioprine: CBC

**DIET**
Low-salt diet. For eGFR <60 mL: Follow National Kidney Foundation guidelines for CKD.

**PATIENT EDUCATION**
- Medication adherence and self-monitoring for relapse.
- Preconception counseling

**PROGNOSIS**
- 10-year survival of 88% and 94% in SLE patients with and without renal involvement
- Relapse rate is ~35%. 10–20% of patients progress to ESRD within 10 years.
- 5-year renal survival of class IV LN <30% before 1970 has improved to >80% in last 2 decades.
- Early and complete remission of proteinuria with treatment is the best prognostic factor. Other predictors of remission include low baseline proteinuria, normal creatinine, Caucasian race, and treatment initiated within 3 months of diagnosis.
- Indicators of poor prognosis: diffuse proliferative LN (especially crescentic), higher activity/chronicity index, APOL 1 risk alleles, African American race, lower socioeconomic status, poor response to treatment, high creatinine at baseline, uncontrolled hypertension, and relapse

**COMPLICATIONS**
- Risks of immunosuppressive therapy: infections, malignancy
- Treatment side effects: Cyclophosphamide causes primary amenorrhea.
- MMF may cause GI upset and nausea and is a teratogen (azathioprine recommended for women who desire pregnancy).
- Risk of vascular thromboses (hypercoagulable state from antiphospholipid antibodies)
- About 10–20% of patients develop ESRD from progressive disease refractory to treatment requiring dialysis/kidney transplantation.
REFERENCES

ADDITIONAL READING

CODES

ICD10
M32.14 Glomerular disease in systemic lupus erythematosus

CLINICAL PEARLS

- Early diagnosis, correct classification (requires renal biopsy), and rapid treatment improve renal survival in patients with LN.
- Treat proliferative/progressive LN with a short induction course followed by maintenance therapy using glucocorticoids and immunosuppressants.
- Due to advances in diagnosis and treatment, survival rates for patients with LN have improved dramatically over the past several decades.
LYME DISEASE
Felix B. Chang Cruz, MD, FAAMA, ABIHM

BASICS
Lyme disease is caused by the bacterium Borrelia burgdorferi.

DESCRIPTION
- A multisystem infection caused by Borrelia spirochetes, transmitted primarily by ixodid ticks
  - Ixodes scapularis (deer ticks) in the Northeast and Great Lakes areas
  - Ixodes pacificus in the West (black-legged ticks and Western black-legged ticks)
  - Ixodes ricinus in Europe
  - Ixodes persulcatus in Asia and Russia
- Early localized Lyme disease includes a characteristic expanding skin rash (erythema migrans [EM]) (80%) and constitutional flulike symptoms (headache, myalgias, fatigue, fever).
- Early disseminated Lyme
  - Neurologic manifestations 15%: cranial nerve palsy, meningitis, acute radiculopathy, or mononeuropathy
  - Multiple EM lesions
- Disseminated Lyme disease presents with involvement of ≥1 organ systems; most commonly neurologic, cardiac, and pauciarticular arthritis
  - Lyme carditis: AV block, myopericarditis 1%
  - Post–Lyme disease syndrome includes arthritis (50%) and chronic neurologic syndromes.
  - System(s) affected: hemic/lymphatic/immunologic; musculoskeletal; skin/exocrine; cardiac; neurologic
- Synonym(s): Lyme arthritis; Lyme borreliosis

EPIDEMIOLOGY
- Each year, approximately 30,000 cases of Lyme disease are reported to the Centers for Disease Control and Prevention (CDC).
- Recent estimates suggest that approximately 300,000 people may get Lyme disease each year in the U.S.

Incidence
- During 2018, a total of 23,558 confirmed cases of Lyme disease were reported to CDC.

Prevalence
- The number of counties with an incidence of ≥10 confirmed cases per 100,000 persons increased from 324 in 2008 to 454 in 2017.
- The most reported vector-borne illness in the United States
- Predominant age: most common in children ages 5–14 years and in adults aged 55–70 years of age

ETIOLOGY AND PATHOPHYSIOLOGY
Infection with spirochete B. burgdorferi in the United States, or Borrelia afzelii or Borrelia garinii in Europe, transmitted by the bite of ixodid ticks. Approximately 90% of cases are transmitted during the nymph stage of the tick life cycle. Average incubation period 7 to 10 days. Most transmissions occur in late May to September when nymphal tick activity is highest. If a tick is infected, the chance of transmission increases with time attached: 12% at 48 hours, 79% at 72 hours, and 94% at 96 hours of attachment. Primary animal reservoir is the white-footed mouse. Spirochetes multiply and spread within dermis, resulting in characteristic (EM) rash. Hematogenous dissemination results in involvement of central nervous system (CNS), cardiovascular, or other organ systems. Star ticks (Amblyomma americanum), the American dog tick (Dermacentor variabilis), the Rocky Mountain wood tick (Dermacentor andersoni), and the brown dog tick (Rhipicephalus sanguineus) are not known to transmit Lyme disease.

**Genetics**
Human leukocyte antigen: Patients with haplotype DR4 or DR2 may be more susceptible to prolonged arthritis.

**RISK FACTORS**
- Exposure in Lyme endemic area, particularly from April to November
- Ixodid ticks are common on deer; hunters at increased risk

**GENERAL PREVENTION**
- “Tick checks”: Examine skin after outdoor activities. Ticks live in grassy, brushy, or wooded areas, and on animals.
- Remove ticks as soon as possible (within 36 hours) to limit transmission.
- Wear clothing covering the ankles in endemic areas.
- Use insect repellents containing N,N-diethyl-meta-toluamide (DEET).
- Apply permethrin to clothes, shoes, and tents.
- Natural products that repel or kill ticks: 2-indecanone, garlic oil, mixed essential oils (rosemary, lemongrass, cedar, peppermint, thyme, and geraniol)
- Biological agent products that repel or kill ticks: Fungus called Metarhizium brunneum/Metarhizium anisopliae
- Antibiotic prophylaxis is recommended for the prevention of Lyme disease in endemic areas following an Ixodes tick bite.
- Prophylactic treatment with 1 dose of 200 mg of doxycycline within 72 hours of a tick that has been attached for at least 36 hours is indicated in endemic areas. Number needed to treat = 50–53. Contraindicated in pregnancy and in children; no prophylactic agent is approved for these groups (1)[A].

**COMMONLY ASSOCIATED CONDITIONS**
- Coinfection (e.g., babesiosis) increasingly reported
- Southern tick–associated rash illness may be mistaken for Lyme disease. It is seen in the Southeastern and South Central United States and is associated with the bite of the lone star tick, A. americanum.
- Comorbid human granulocytic anaplasmosis and/or babesiosis in patients living in endemic regions
DIAGNOSIS

HISTORY
- History of a tick bite followed by EM and/or illness (fever, fatigue, headache, myalgias). Only about 1/3 of patients recall tick bite.
- Round, flat or raised, erythematous bulls-eye lesion that expands in diameter over days to weeks that has an area of central clearing.
- Common EM sites: axilla, back, abdomen, groin, or popliteal fossa
- 75–80% presenting with EM having a single lesion
- Early Lyme disease: incubation period 3 to 30 days
  - Some patients may be asymptomatic (2).
  - Fever; headache; myalgias; arthralgias, regional lymphadenopathy
- Early disseminated Lyme disease
  - Carditis (pleuritic chest pain; palpitations)
  - Facial palsies or other cranial neuropathies
  - Joint pain (polyarthritis/polyarthralgia; late disease: monoarthritis-like knee)
  - Iritis, conjunctivitis
  - Migratory musculoskeletal pain
- Late Lyme disease arises months after exposure.
  - Recurrent synovitis
  - Recurrent tendonitis and bursitis
  - Encephalopathic symptoms
    - Severe headaches and neck stiffness
    - Confusion
    - Facial palsy
    - Nerve pain
  - Symptoms mimicking other CNS diseases
    - Multiple sclerosis–like symptoms
    - Stroke-like symptoms
    - Transverse myelitis
  - Peripheral neuropathic symptoms: motor, sensory, or autonomic neuropathies
  - Meningitis
  - Acrodermatitis chronica atrophicans: fibrosing skin process often involving extremities

PHYSICAL EXAM
- Early Lyme disease
  - EM 70–80%
- Disseminated Lyme disease
  - Multiple EM lesions
  - Facial palsies or other cranial neuropathies
  - Heart block—irregular pulse, bradycardia
  - Pericarditis—friction rub
  - Arthritis
  - Other focal neurologic findings

DIFFERENTIAL DIAGNOSIS
- Other tick-borne illnesses: Rocky Mountain spotted fever (RMSF), ehrlichiosis, babesiosis
Juvenile rheumatoid arthritis (RA); systemic lupus erythematosus (SLE); RA
Viral syndromes
Contact dermatitis; cellulitis; granuloma annulare (mimic EM)
Syphilis
AV block
Malignant neoplastic diseases

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Testing and treatment not indicated if tick attached for <48 hours
- Diagnosis is based mainly on clinical findings in endemic areas (2).
- Serology: enzyme-linked immunosorbent assay (ELISA) for IgM and IgG B. burgdorferi antibodies, followed by a Western blot test if positive or equivocal, or an indirect immunofluorescence assay
- Culture of CSF for B. burgdorferi
- Plasma polymerase chain reaction (PCR) testing is of little value (only exception is synovial fluid analysis).
- No imaging routinely indicated
- For non-EM presentations: Two-tier serologic testing is recommended, synovial fluid when arthritis is suspected, and CSF analysis when neurologic involvement suspected.
- Tests yet to be validated:
  - Urine antigen capture assays
  - Culture, immunofluorescence staining, or cell sorting of cell wall-deficient or cystic forms of B. burgdorferi
  - Lymphocyte transformation tests
  - Quantitative CD57 lymphocyte assays
  - “Reverse Western blots”
  - In-house criteria for interpretation of immunoblots
  - Measurements of antibodies in joint fluid (synovial fluid)
  - IgM or IgG tests without a previous ELISA/enzyme immunoassay/immunofluorescent antibody

**Follow-Up Tests & Special Considerations**
Disorders that may alter lab results: false-positive response with RMSF, syphilis, SLE, and RA
- Arthritis: Serology + PCR of synovial fluid is both sensitive and specific.
- Neuroborreliosis: serology + CSF pleocytosis (PCR of CSF has a very low sensitivity.)
- Late-stage disease with negative serology may be seen in patients receiving early antibiotic treatment.
- After an infection, antibodies may persist for months to years. Serologic tests do not distinguish active from past infection.
- Antibodies are not protective.

**Diagnostic Procedures/Other**
- Lumbar puncture when neurologic findings are present, with ELISA or CSF for B. burgdorferi antibodies (2)
- Arthrocentesis when arthritis is present with serology and PCR testing

**Test Interpretation**
Culture of B. burgdorferi from blood or skin has low yield.

**TREATMENT**

**GENERAL MEASURES**
Early and disseminated Lyme disease can usually be treated as an outpatient, except when complicated by carditis or meningitis (requires parenteral antibiotics).

**MEDICATION**

**First Line**

- Early Lyme disease (3)[A]
  - Doxycycline 100 mg PO BID for 10 to 21 days (do not use in children <8 years old or in pregnant women); or
  - Amoxicillin 500 mg PO TID for 14 to 21 days (pediatric dose 50 mg/kg/day); or
  - Cefuroxime axetil 500 mg PO BID for 14 to 21 days
    - Doxycycline has the advantage of covering other tick-borne infections such as ehrlichiosis, anaplasmosis, and RMSF.
    - Alternative: azithromycin 500 mg QD for 7 to 10 days or clarithromycin 500 mg BID for 14 to 21 days

- Early disseminated Lyme
  - Neurologic disease
    - Normal CSF, treat for 14 to 21 days.
    - Doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID
    - Abnormal CSF, treat for 4 weeks: ceftriaxone 2 g QD IV, cefotaxime 2 g q8h, or penicillin G 5 mIU q6h
  - Cardiac disease
    - Mild (first-degree AV block, PR <300 ms): doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID for 14 to 21 days
    - More serious: ceftriaxone 2 g QD IV for 30 days
  - Arthritis
    - Oral treatment for 28 days with doxycycline 100 mg BID or amoxicillin 500 mg TID
    - If oral treatment fails, repeat oral regimen for 28 days or begin IV treatment with ceftriaxone 2 g QD for 2 to 4 weeks.

- Contraindications
  - Allergy to specific medication
  - Doxycycline is contraindicated in children and in women who are pregnant or breastfeeding.

- Precautions
  - In ~15% of patients treated with IV therapy, a Jarisch-Herxheimer–type reaction develops within 24 hours of initiation of therapy.

- Significant possible interactions:
  - Oral anticoagulants may require dose adjustments.
  - Oral contraceptives may be less effective.

**Pediatric Considerations**

- Amoxicillin is the drug of choice in children; 50 mg/kg/day PO divided in 3 doses
Tetracyclines are contraindicated.

**Pregnancy Considerations**
- Because *B. burgdorferi* can cross the placenta, pregnant patients with active disease should be treated with parenteral antibiotics.
- Doxycycline should not be used in pregnancy.
- Treatment for pregnant women is similar to that on nonpregnant adults and includes oral amoxicillin or oral cefuroxime axetil for 2–3 weeks.
- There are no reports of Lyme disease transmission through breast milk.

**Second Line**
- Azithromycin, 500 mg PO daily for 7 days, can be used for those allergic to β-lactams and unable to take tetracyclines but is less effective (3)[A].
- There is no evidence for meaningful clinical benefit from prolonged treatment or retreatment of patients with persistent unexplained symptoms despite previous antibiotic treatment of Lyme disease.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission is recommended for patients with Lyme carditis and symptoms of chest pain, syncope, or dyspnea and for those with second- or third-degree heart block or first-degree heart block of ≥300 ms.
- Admission is also recommended for patients with symptoms of meningitis.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Based on the severity of symptoms, patients with Lyme carditis, neurologic syndromes, or arthritis may require prolonged follow-up.

**DIET**
No restrictions

**PATIENT EDUCATION**
- In endemic areas, patients should be advised to protect themselves against tick exposure.
- Avoid “painting” the tick with nail polish or petroleum jelly, or using heat to make the tick detach from the skin. Remove the tick as quickly as possible.
- Prevention
  - Use repellents that contain 20–30% DEET on exposed skin and clothing for protection lasting several hours.
  - Use 0.5% permethrin on clothing.
  - Bathe or shower as soon as possible after coming indoors (preferably within 2 hours) and perform regular tick checks after outdoor activities.

**PROGNOSIS**
- Early treatment with antibiotics can shorten the duration of symptoms and prevent later disease.
Response of late-stage disease to treatment is variable. Symptoms may take weeks to resolve after beginning treatment.

- Untreated rash usually resolves in 3 to 4 weeks.
- Excellent long-term prognosis with early antibiotic treatment
- Neurologic symptoms arise in about 15% of untreated Lyme disease patients.

COMPLICATIONS

- No consensus definition of post-Lyme syndrome
- No convincing evidence for chronic Lyme infection
- Some patients report lasting symptoms:
  - Recurrent synovitis, tendonitis, bursitis
  - Chronic neurologic symptoms
  - Peripheral neuropathies
  - Post-treatment Lyme disease syndrome: 10–20% lingering symptoms of fatigue, pain, or joint and muscle aches; can last for 6 months
- Lyme carditis >40% syncopal presentation

REFERENCES

ADDITIONAL READING

CODES

ICD10

- A69.20 Lyme disease, unspecified
- A69.23 Arthritis due to Lyme disease
- A69.21 Meningitis due to Lyme disease

CLINICAL PEARLS
The presence of EM following a tick bite in an endemic area is an indication for empiric antibiotic treatment for presumptive Lyme disease.

- Ticks must be attached for at least 36 to 48 hours to transmit Lyme disease.
- Lyme can present as early disease, early disseminated disease, or late disseminated disease
- Perform routine tick checks after outdoors activities in endemic areas and remove any attached ticks as quickly as possible.
LYMPHANGITIS
Amar Kapur, DO

BASICS

DESCRIPTION
Acute or chronic inflammation of lymphatic channels; presents as red, tender streaks extending to regional lymph nodes
- May result from compromised lymphatic drainage following surgical procedures
- May be infectious or noninfectious

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute infection
  - Usually caused by group A β-hemolytic Streptococcus
  - Less commonly caused by:
    o Staphylococcus aureus
    o Pasteurella multocida
    o Erysipelothrix
    o Spirillum minus (rat bite disease)
    o Pseudomonas
    o Other Streptococcus sp.
    o Immunocompromised patients can be infected with gram-negative rods, gram-negative bacilli, or fungi.
    o In fresh water exposures, Aeromonas hydrophila
- Nodular lymphangitis
  - Also known as sporotrichoid lymphangitis
  - Painful or painless nodular subcutaneous swellings along lymphatic vessels
  - Lesions may ulcerate with accompanying regional lymphadenopathy.
  - Typical of infections from: Sporothrix schenckii, Nocardia brasiliensis, Mycobacterium marinum, leishmaniasis, tularemia, and systemic mycoses
  - Pathology may show granulomas.
- Noninfectious granulomatous lymphangitis
  - Rare-acquired lymphedema of the genitalia in children
  - May be due to atypical Crohn disease or sarcoidosis (1)[C]
- Filarial lymphangitis
  - Mosquito bites transmit parasites causing lymphatic inflammation and dilatation; can predispose to secondary bacterial infection
  - Usually caused by nematodes Wuchereria bancrofti. Other causes include Brugia malayi and Brugia timori.
- Lymphangitis can occur after surgical procedures and lymph node dissection.
- Cutaneous lymphangitis carcinomatosa is rare. Represents ~5% of all skin metastases; caused by neoplastic occlusion of dermal lymphatic vessels (2)
- Sclerosing lymphangitis of the penis
  - Swelling around coronal sulcus of penis as a result of vigorous sexual activity or masturbation
RISK FACTORS
- Impaired lymphatic drainage due to surgery, nodal dissection, or irradiation
- Diabetes mellitus
- Chronic steroid use
- Peripheral venous catheter
- Varicella infection
- Immunocompromising condition
- Human, animal, or insect bites; skin trauma
- Fungal, bacterial, or mycobacterial skin infections
- IV drug abuse
- Residence in endemic areas of filariasis

GENERAL PREVENTION
- Reduce chronic lymphedema with compression devices or by treating underlying process.
- Insect repellent; arthropod bite precautions
- Proper wound and skin care

COMMONLY ASSOCIATED CONDITIONS
- Lymphedema
- Prior lymph node dissection
- Tinea pedis (athlete’s foot)
- Sporotrichosis
- Cellulitis, erysipelas
- Filarial infection (W. bancrofti)

DIAGNOSIS

HISTORY
- Trauma to skin, cut, abrasion, or fungal infection
- Systemic symptoms:
  - Malaise
  - Fever and chills
  - Loss of appetite
  - Headache
  - Muscle aches
- Travel to a tropical zone or region with filariasis

PHYSICAL EXAM
Local signs:
- Erythematous, macular linear streaks from site of infection toward regional lymph nodes
- Tenderness and warmth over affected skin or lymph nodes
- Blistering of affected skin
- Fluctuance, swelling, or purulent drainage
- Nodular lymphangitis can present with subcutaneous swellings along the lymphatic channels.
- Sporotrichosis may present with papulonodular lesions that may ulcerate.
- Sites may be painless.
DIFFERENTIAL DIAGNOSIS
- Superficial thrombophlebitis
  - Thrombus or infection within the thrombosis (septic thrombophlebitis)
- Contact dermatitis
- Allergic reaction: less likely to be allergic if >24 hours after exposure (e.g., insect bite)
- Lymphangitis carcinomatosa
- Malignancy-related inflammation

DIAGNOSTIC TESTS & INTERPRETATION
- CBC may show leukocytosis; blood smear may show filarial infection.
- Blood or wound cultures
- Biopsy cultures
- FNAC for filariasis of testiculoscrotal swelling but not for other superficial locations (3)

Initial Tests (lab, imaging)
Plain films are unnecessary; consider lymphangiography for lymphedema (4)[C].

Diagnostic Procedures/Other
- Swab, aspirate, and/or biopsy primary site; purulent discharge; nodule or distal ulcer for culture; acid fast staining; histology; and microscopy
- Blood cultures if systemically ill
- Serology (e.g., Francisella tularensis, histoplasma)
- Blood film/smear (e.g., filaria)
- Lymphangiography to determine lymphedema or lymphatic obstruction

TREATMENT

GENERAL MEASURES
- Hot, moist compresses to affected area
- Compression garments and weight loss may help lymphedema.
- Abstinence from sexual activity (for sclerosing lymphangitis)

MEDICATION
- Treat common organisms empirically. Use culture and susceptibility to guide antibiotic treatment.
- If mild disease, outpatient oral antibiotics
- If no improvement after 48 hours of oral antibiotics, reassess and consider IV antibiotics and/or hospitalization.
- IV antibiotics if systemically ill
- If necrotizing fasciitis is suspected, treat aggressively with antibiotics and surgical intervention.

First Line
Antibiotics for group A streptococcal infection
- Amoxicillin (if known group A Streptococcus)
  - Dosing
    - Adults
- **Mild to moderate:** 500 mg PO q12h
- **Severe:** 875 mg PO q12h or 500 mg PO q8h
  - Children <3 months: 30 mg/kg/day PO divided q12h
  - Children ≥3 months, ≤40 kg
    - **Mild to moderate:** 25 mg/kg/day PO divided q12h or 20 mg/kg/day divided q8h
    - **Severe:** 45 mg/kg/day PO divided q12h or 40 mg/kg/day divided q8h
  - Children ≥40 kg same as adult dosing
- **Common adverse effects**
  - Diarrhea
- **Serious adverse effects**
  - Anaphylaxis, Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN)
- **Drug interactions**
  - Methotrexate, venlafaxine, warfarin, hormonal contraceptives
- **Contraindications**
  - Hypersensitivity to penicillin

- **Ampicillin/subactam**
  - **Dosing**
    - Adults and children ≥40 kg: 1.5 to 3.0 g IV/IM q6h
    - Children <40 kg: 200 mg/kg/day IV infusion, in divided doses q6h; maximum 8 g ampicillin per day
  - **Common adverse effects**
    - Diarrhea, injection site reactions
  - **Serious adverse effects**
    - Clostridium difficile diarrhea, pseudomembranous enterocolitis
  - **Drug interactions**
    - Hormonal contraceptives
  - **Contraindications**
    - Hypersensitivity reactions

- **Ceftriaxone**
  - **Dosing**
    - Adults: 1 to 2 g IV/IM q24h
    - Children: 50 to 75 mg/kg/day IV/IM once daily or in divided doses q12h; maximum 2 g/day
  - **Common adverse effects**
    - Injection site reactions, diarrhea
  - **Serious adverse effects**
    - Same as amoxicillin or ampicillin
  - **Drug interactions**
    - Do not administer calcium-containing solutions in the same IV line.
  - **Contraindications**
    - Hypersensitivity to cephalosporins
    - Concurrent calcium-containing IV fluids
    - Increased risk of kernicterus, salt precipitation in lungs and kidneys in neonates <28 days (use cefotaxime instead)

- **Cephalexin**
  - **Dosing**
Adults: 500 mg PO q12h
Children: 25 to 50 mg/kg/day divided q12h

- **Common adverse effects**
  - Diarrhea
- **Serious adverse effects**
  - SJS, TEN, interstitial nephritis, renal failure, pseudomembranous enterocolitis, anaphylaxis
- **Contraindications**
  - Hypersensitivity to cephalosporins

**Azithromycin (if penicillin or cephalosporin allergy)**

- **Dosing**
  - Adults: 500 mg PO on day 1 followed by 250 mg/day PO on days 2 to 5
  - Children ≥2 years: 12 mg/kg/day PO (maximum dose: 500 mg/day) once daily for 5 days
    (FDA off-label use for skin infections in children)
- **Common adverse effects**
  - Abdominal pain, nausea, vomiting, diarrhea, headache
- **Serious adverse effects**
  - Prolonged QT interval, torsades de pointes, liver failure, Lambert-Eaton syndrome, myasthenia gravis, corneal erosion, anaphylaxis
- **Drug interactions**
  - Nelfinavir, warfarin, other medications with potential to prolong QT interval
- **Contraindications**
  - Hepatic dysfunction or cholestatic jaundice with prior treatment
  - Hypersensitivity to macrolide (azithromycin, erythromycin, clarithromycin)

**Diethylcarbamazine, ivermectin, albendazole, and doxycycline are used to treat filarial infection.**

**Acetaminophen or ibuprofen (NSAIDs) for pain and fever**

**SURGERY/OTHER PROCEDURES**

- Incision and drainage of abscess if present
- Necrotizing fasciitis requires surgical evaluation and likely débridement.
- Nodular lymphangitis may benefit from I&D.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admit for signs of serious illness: fluids if in hypotensive shock.
- Fever, chills, systemic toxicity
- IV antibiotics, ICU, or surgery as indicated
- Discharge on oral antibiotics after systemic symptoms resolve. Home IV antibiotics are an option depending on clinical setting.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Elevate affected area.
- 48-hour follow-up to ensure improvement
- Work up recurrent lymphangitis to ascertain underlying cause (other infectious organism,
anatomic abnormality, etc.).

**Patient Monitoring**
Close follow-up to ensure decreasing inflammation

**PATIENT EDUCATION**
Instruct patients on proper wound and skin care.

**PROGNOSIS**
- Good prognosis for uncomplicated cases
- Antimicrobial therapy is effective in 90% of patients.
- Untreated, can spread rapidly, especially group A Streptococcus

**COMPLICATIONS**
Sepsis, cellulitis, necrotizing fasciitis, myositis

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- I89.1 Lymphangitis
- L03.91 Acute lymphangitis, unspecified
- N48.29 Other inflammatory disorders of penis

**CLINICAL PEARLS**
- Lymphangitis classically presents with erythematous linear streaks of the skin from site of entry (e.g., bite, cut, abrasion) to regional lymph nodes.
- Patients with prior surgical lymph node dissection are predisposed to lymphangitis.
- Patients with severe systemic symptoms should be admitted for treatment with IV antibiotics.
- Parasitic or fungal infections can cause acute or chronic lymphangitis.
- Treatment of underlying skin infection (such as tinea pedis) may prevent recurrence.
LYMPHEDEMA
Khalid Bashir, MD

BASICS

DESCRIPTION
- Accumulation of lymphatic fluid in the interstitial tissue causing swelling
- Lymphedema can develop when lymphatic vessels are missing or impaired (primary) or when lymph vessels are damaged or lymph nodes are removed (secondary).
- Most common in the lower limb(s) (80%) but also can occur in the arm(s), face, trunk, and external genitalia

EPIDEMIOLOGY

Incidence
- Predominant sex: female > male
- Predominant age: any age
- 13% of patients with breast cancer treated with surgery; 42% of those treated with surgery and radiation therapy; 25% after GYN cancer surgery
- Milroy disease presents at birth; estimated to be between 1/6,000 and 1/300 live births
- Meige disease develops during puberty.

Prevalence
- 120 million people worldwide are affected with lymphatic filariasis in 73 countries but no primary infections in United States.
- 10 million people are affected by nonfilarial secondary lymphedema in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

Secondary lymphedema:
- Postoperative: gradual failure of distal lymphatics, which have to "pump" lymph at a greater pressure through damaged proximal ducts
- Risk is higher with postoperative radiation because radiation reduces regrowth of ducts due to fibrous scarring.
- Trauma; recurrent infection; malignancy, including metastatic disease; and marked obesity
- Lymphangiogenesis inhibition and tissue fibrosis promotion by T cells appear to promote lymphedema.
- Developing countries: Most common cause is filariasis (Wuchereria bancrofti).

Genetics
- Milroy disease: autosomal dominant; diagnosed either at birth or the 1st year of life
- Lymphedema praecox has onset between the ages of 1 and 35 years.
- Lymphedema tarda occurs in those >35 years of age.
- Genetics referral: primary and lymphedema tarda

RISK FACTORS
- Filariasis: most common cause worldwide
- Mastectomy, melanoma surgery
Prior trauma, serious burns, infection of affected limb
- Lymphadenectomy or radiation therapy for malignancy
- Obesity (>50 body mass index)
- Inflammatory disorders: arthritis, sarcoidosis, dermatitis

**GENERAL PREVENTION**
Healthy body weight maintenance; treatment of congestive heart failure (CHF), early recognition of infection and cancer, and venous insufficiency

**COMMONLY ASSOCIATED CONDITIONS**
Venous disease, morbid obesity, regional cancer, filarial disease (Africa and Asia)

**DIAGNOSIS**

**HISTORY**
Recent surgery: Vein stripping can significantly exacerbate mild lymphedema:
- First symptom: painless swelling
- Feeling of heaviness in the limb, especially at the end of the day and in hot weather

**ALERT**
After 1st year, edema becomes nonpitting.

**PHYSICAL EXAM**
- Initial: pitting edema, can spread proximally or distally
- Later: nonpitting; after 1st year, does not spread proximally/distally, but spreads radially
- Hyperkeratosis (thicker skin)
- Papillomatosis (rough skin)
- Increase in skin turgor
- Positive Stemmer sign (inability to pinch the skin of the dorsum of the second toe between the thumb and forefinger); false positives are rare.

**DIFFERENTIAL DIAGNOSIS**
- CHF, renal failure, lipedema
- Hypoalbuminemia, protein-losing nephropathy
- Deep vein thrombosis (DVT), chronic venous disease
- Postoperative complications following ipsilateral surgery
- Cellulitis, Baker cyst, idiopathic edema

**DIAGNOSTIC TESTS & INTERPRETATION**
- Lack of response to elevation or diuretic therapy may indicate a lymphatic insufficiency.
- Diuretics increase excretion of salt and water, thereby decreasing plasma volume, venous capillary pressure, and filtration. Diuretics improve filtration edema but do not improve lymph drainage over the long term.
- Some relevant protein biomarkers for lymphedema have been identified and show promise for early- and latent-stage diagnosis.

**Initial Tests (lab, imaging)**
- Comprehensive chemistry panel: hepatic or renal impairment
TSH: hypothyroidism
Urinalysis: protein-losing nephropathy
Ultrasound: evaluates for acute/chronic DVT; gives information about soft tissue changes but does not inform about truncal anatomy of the lymphatics
Duplex ultrasound: Lymphedema causes gradual impedance of venous return that aggravates the edema; 82% of patients with unexplained limb edema were diagnosed using a combination of duplex ultrasound and lymphoscintigram.

Follow-Up Tests & Special Considerations
- Lymphangiogram: direct cannulation of lymphatics through the skin; risk for infection, local inflammation; rarely used now
- Fluorescence microlymphography may be highly sensitive (91.4%) and specific (85.7%), atraumatic, and is without radiation in diagnosis of leg lymphedema.
- Lymphoscintigram: radiolabeled protein technetium-99m–labeled colloid
  - Measures lymphatic function, lymph movement, lymph drainage, and response to treatment
  - Sensitivity, 73–97%; specificity, 100%
  - Best to use 1 hour and delayed images together
- Indocyanine green lymphography: reported
  - Superior to lymphoscintigraphy in early diagnosis of arm
  - Accurately screens postsurgically for subclinical lymphedema (1)
- CT scan: calf skin thickening, thickening of the subcutaneous (SC) compartment, increased fat density, thickened perimuscular aponeurosis; typical honeycomb appearance
- MRI: circumferential edema, increased volume of SC tissue, honeycomb pattern above the fascia between the muscle and subcutis; cannot differentiate primary from secondary lymphedema

TREATMENT

GENERAL MEASURES
- Seek optimal weight; early treatment of cellulitis; avoid trauma to affected area (direct injury, venipunctures, inept nail care, extreme heat/cold).
- Achieve mechanical reduction and maintenance of limb size: compression garments via professionals.
- Elevate affected limb/area, but avoid stasis.
- Avoid blood pressure (BP) cuffs and other focal constriction in affected limbs.
- Prevent skin infection with daily cleansing, inspection, and skin care (with emollients).
- Nonsurgical treatment of varicose veins in some
- Doubtful that air travel is associated with increased limb volumes

MEDICATION

ALERT
No medications, including diuretics, are useful.

ISSUES FOR REFERRAL
- Refer to physical therapist with lymphedema training for manual decongestive therapy.
  - In patients with recurrent or metastatic disease, discuss with oncologist prior to initiation of
complete decongestive therapy in order not to promote the spread of cancer.

- Provide education for patient/family for self-administration of therapy in future.
- Education for family about bandaging
- Fitting for compression garments (2)[A]

ADDITIONAL THERAPIES

- Exercise: Lymph flow occurs as a result of inspiratory reduction in the intrathoracic pressure associated with inspiration. Best results are achieved with combination of flexibility, strength, and aerobic training.
- Compression with custom-made elastic stocking (minimum pressure is 40 mm Hg)
  - Protection against external incidental trauma
  - Decreases the intrinsic trauma on the skin due to chronically increased interstitial pressures, which cause stretch of the skin and SC tissues
  - No data on preference of custom made versus prefabricated
  - Replace every 3 to 6 months or when starting to lose elasticity
- Multilayer bandaging: inner layer of tubular stockinette followed by foam and padding to protect the joint flexures and to even out the contours of the limb so that pressure is distributed evenly; outer layer of at least two short-stretch extensible bandages; more effective than hosiery alone
- Pneumatic pumps develop high pressures like systolic BP and can reduce limb girth significantly; wear a compression sock afterward (2)[A].
- Advanced pneumatic compression devices (APCDs) are programmable, offer a more individualized fit, reduce rates of cellulitis by at least 75%, and reduce early treatment costs by 37–54% depending on health care setting (3)[B].

SURGERY/OTHER PROCEDURES

- Bypass procedures: Creation of lymphatic–venous anastomosis or lymph node transplantation (most effective) via microsurgery showed a reduction in use of conservative compression therapy (4)[C]: reserved for refractory cases only
- Low-level laser therapy in smaller studies was shown to be noninferior to manual lymphatic drainage or in combination in arm volume reduction among breast cancer patients in half the treatment time (4)[C].
- Axillary reverse mapping during axillary node dissection in selected preclinical breast cancer can significantly reduce lymphedema incidence (5)[A].
- Debulking procedures (Charles procedure): radical excision of SC tissue with primary or staged skin grafting
  - Men had less improvement than women.
  - Main risk is infection and necrosis of the skin graft.
  - Liposuction is cosmetically preferred to debulking (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Heat therapy: Microwave and electromagnetic irradiation may be helpful.
- Selenium ingestion has been reported to reduce lymphedema volume (not approved indication in United States).
Benzopyrene oral medicine (flavonoids and coumarin; neither are approved in the United States)
- Flavonoids: Micronized purified flavonoid fraction (Daflon 500 mg) reported to decrease venous stasis and idiopathic cyclic edema, chronic venous insufficiency, and postmastectomy lymphedema.
- Coumarin reduces edema fluid by increasing the number of macrophages and enhancing proteolysis, resulting in the removal of protein, some reports of bleeding, and hepatotoxicity (4)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Systemic signs of infection
  - May admit to specialized rehabilitation unit for combination treatment in patients with heart failure or severe pulmonary disease
  - IV antibiotics for infection; cellulitis is most common.
- Affected extremity positioning with some distal elevation
- Encourage patient mobilization/exercise.
- Patient education for bandaging/wound care
- Discharge criteria
  - Improved signs/symptoms of infection (e.g., elevated white blood cell count, fever, abnormal vital signs)
  - Clinical improvement in wound appearance

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Lymphedema will return in several days if patient stops wearing compression garments during the day and bandaging at night.

Patient Monitoring
- Daily visit to therapist for acute treatment
- Monthly visits for maintenance care

DIET
Lower sodium, healthy protein, and weight loss-oriented (if needed)

PATIENT EDUCATION
- Use compression garments, especially when exercising.
- Avoid affected limb(s) being dependent for long period of time: Patient should perform daily skin examination.

PROGNOSIS
No cure, but treatment can produce good results with daily care.

COMPLICATIONS
- Infection (local vs. systemic): common
- Risk of wound formation (punctures/abrasions) that are difficult to heal: common
Lymphangiosarcoma: found in lymphedematous arms of patients following radical mastectomy, also in patients with Milroy disease. Treatment is radiotherapy with surgery; reserved for patients with discrete nonmetastatic disease.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- I89.0 Lymphedema, not elsewhere classified
- Q82.0 Hereditary lymphedema
- I97.89 Oth postproc comp and disorders of the circ sys, NEC

CLINICAL PEARLS

- Affected skin has a heavy feeling, with painless swelling initially, later nonpitting swelling
- No medications, including diuretics, are useful.
- Rule out DVT if unilateral limb or CHF if bilateral.
- Early referral to lymphedema therapist for manual therapy, compression devices/wrappings
- Aggressive weight loss and health promotion as needed
- High risk for cutaneous-sourced infections, so promote therapeutic skin care.
- Lymphoscintigram is standard diagnostic if clinic diagnosis is uncertain, and refer primary lymphedema and lymphedema tarda to genetics.
BASICS

DESCRIPTION

- Age-related macular degeneration (ARMD) is the leading cause of irreversible, severe visual loss in persons age >65 years.
- ARMD can be classified as:
  - Atrophic/nonexudative, such as drusen or macular pigmentary changes
  - Neovascular/exudative

EPIDEMIOLOGY

- Neovascular/exudative form is rare in blacks and more common in whites.
- Predominant sex: female

Incidence

- In the Framingham Eye Study (FES), drusen were noted in 25% of all participants who were ≥52 years of age. ARMD-associated visual loss was noted in 5.7%.
- Atrophic/nonexudative stage accounts for 20% of cases of severe visual loss.
- Neovascular/exudative stage accounts for 80% of cases of severe visual loss.

Prevalence

- Per FES study:
  - People 65 to 74 years old: 11%
  - People ≥75 years old: 27.9%

ETIOLOGY AND PATHOPHYSIOLOGY

- Atrophic/nonexudative
  - Visible light can result in the formation and accumulation of metabolic by-products in the retinal pigment epithelium (RPE), a pigment layer underneath the retina that normally helps remove metabolic by-products from the retina. Excess accumulation of these metabolic by-products interferes with the normal metabolic activity of the RPE and can lead to the formation of drusen.
  - Drusen and/or pigmentary changes in the macula. Drusen are deposits of hyaline material between the RPE and Bruch membrane (the limiting membrane between the RPE and the choroid)
  - Most do not progress beyond the atrophic/nonexudative stage; however, those who do are at a greater risk of severe visual loss.

- Neovascular/exudative
  - Neovascular stage generally arises from the atrophic stage.
    - In type 1 neovascularization, breaks in the Bruch membrane allow choroidal neovascular membranes (CNVMs) to grow in the sub-RPE space. This corresponds to occult CNVMs. Fluid leakage and bleeding can produce a vascularized serous or fibrovascular RPE detachment.
    - In type 2 neovascularization, the CNVM passes through the RPE and is located in the
subretinal space. Typically appears as a lacy or gray-green lesion. This corresponds to classic CNVM.

- Type 3 neovascularization, also known as retinal angiomatous proliferations (RAPS), the neovascularization develops from the deep capillary plexus of retina and grows downward toward the RPE.
- Polypoidal choroidal vasculopathy is a subtype of exudative ARMD and often presents with multiple, recurrent serosanguineous RPE detachments.

**Genetics**
- Genetic susceptibility may be a factor in ARMD: ~25% genetically determined
- Complement factor H Y402H genotype is an important susceptibility gene for ARMD.
- Although the development of ARMD may be predicted by specific alleles, the clinical response to antivascular endothelial growth factor (VEGF) is not.

**RISK FACTORS**
- Obesity
- Ethnicity: non-Hispanic whites
- Cigarette smoking
- Chlamydia pneumoniae infection
- Family history
- Excess sunlight exposure
- Blue or light iris color
- Hyperopia
- History of cardiovascular disease
- Short stature
- High plasma high-density lipoprotein cholesterol levels are associated with an increased risk for ARMD.
- Physical activity is associated with lower risk of early and late ARMD in white populations.
- Female sex

**GENERAL PREVENTION**
- Ultraviolet (UV) protection for eyes
- Routine ophthalmologic visits
  - Every 2 to 4 years for patients age 40 to 64 years
  - Every 1 to 2 years after age 65 years

**DIAGNOSIS**

**HISTORY**
Patients frequently notice distortion of central vision. On Amsler grid testing, the horizontal or vertical lines may become broken, distorted, or missing.

**PHYSICAL EXAM**
- Atrophic/nonexudative stage
  - Drusen (small yellowish white lesions)
    - Subtypes: hard drusen and soft drusen
  - Atrophy of the RPE
When the area of absent or attenuated RPE is contiguous, the condition is termed geographic atrophy (GA) of the RPE.

- Neovascular/exudative stage
  - Blood vessels growing underneath the retina from the choroid are called CNVMs or subretinal neovascularization (SRN). The choroid is the vascular layer underneath the RPE.
  - Subretinal fluid or hemorrhage
  - Exudates
- Disciform scar: an advanced stage resulting in a fibrovascular scar

**DIFFERENTIAL DIAGNOSIS**
- Idiopathic SRN
- Presumed ocular histoplasmosis syndrome
- Diabetic retinopathy
- Hypertensive retinopathy
- Central serous chorioretinopathy
- Topiramate can cause a macular neurosensory retinal detachment.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**
- Fluorescein angiography (FA)
  - Detection of CNVMs
  - Differentiates between atrophic and neovascular ARMD
- Indocyanine green video angiography: may identify occult or hidden CNVMs
- Optical coherence tomography (OCT) is useful in determining the presence of subretinal fluid, the degree of retinal thickening, and the presence of a pigment epithelial detachment (PED).
  - Newer generation OCT modalities, including spectral domain OCT (SD-OCT) and OCT angiography (OCTA) are preferred for evaluating ARMD.
  - OCTA visualized anatomic subtypes of neovascularization include type 1 (sub-RPE), type 2 (subretinal), and type 3 (intraretinal vascular proliferation).

**TREATMENT**

**GENERAL MEASURES**
Low-vision aids may be helpful.

**MEDICATION**

**First Line**
- Ranibizumab (Lucentis)
  - Antibody fragment that inhibits all active forms of VEGF
  - Injected intravitreally, at a dose of 0.5 mg, every 4 weeks.
  - 1 year after treatment, up to 40% of patients treated with ranibizumab gained at least three lines of vision, and ~95% maintained vision.
  - The PrONT0 study demonstrated OCT-guided, variable-dosing regimen with ranibizumab resulted in similar results to the MARINA (minimally classic/occult CNVM trial) and ANCHOR (predominantly classic CNVM trial) studies with monthly injections of ranibizumab.
When comparing ranibizumab and bevacizumab in a multicenter study, both treatments were effective in stabilizing visual loss, and no difference was found in the visual outcome between the two treatment groups.

- In this study, treatment as needed resulted in less gain in visual acuity, whether instituted at enrollment or after 1 year of monthly treatment.
- Visual gains during the first 2 years were not maintained at 5 years. At the 5-year visit, 50% of eyes had vision of 20/40 or better and 20% had vision of 20/200 or worse (1)[A].

Eyes with ≥50% of the lesion composed of blood had a similar visual prognosis compared to other treated eyes in the Comparison of Age-related Macular Degeneration Treatments Trials (CATT). Neovascular ARMD lesions composed of >50% blood can be managed similarly to those with less or no blood.

- The treat and extend regimen (TER) is commonly used to decrease the treatment burden. Once no signs of CNVM activity are detected, patient follow-ups and treatments are then extended by intervals of 2 weeks as long as no signs of CNVM activity are present, up to a maximum interval of 12 weeks. If examination shows any sign of recurrence, the interval is shortened by 2 weeks at a time, until the disease is considered to be inactive. Interval extension is then restarted, with the maximum final interval being 2 weeks less than the period when the previous recurrence was observed.

- Aflibercept (Eylea)
  - A VEGF receptor decoy that binds both VEGF and placental-like growth factor
  - Injected intravitreally, at a dose of 2 mg, every 4 weeks for 12 weeks and then every 8 weeks
  - Dosed as needed after the 12-week fixed dosing schedule resulted in a 5.3-letter gain in best corrected visual acuity at 52 weeks.
  - Routine use of prophylactic antibiotics after intravitreal injections (IVIs) may be unnecessary.
  - May be beneficial in patients who are not responding to ranibizumab or bevacizumab.
  - Anti-VEGF treatment with either ranibizumab or aflibercept showed limited efficacy for the complete resolution of PED.
  - Patients with a PED tend to have worse outcomes when switched from a fixed regimen to a PRN strategy.

**Second Line**

- Bevacizumab (Avastin) is a full-length antibody to VEGF, administered intravitreally at a dose of 1.25 mg; widely used off-label because of its lower cost
- Brolucizumab is being investigated. It is a humanized single-chain antibody fragment that inhibits all isoforms of VEGF-A. It is the smallest of the anti-VEGF antibodies. A 12-week treatment cycle may be a viable option, which would help reduce the frequency of IVIs (2)[B].
- Conbercept is being investigated for the treatment of neovascular age-related macular degeneration. It has high affinity for all isoforms of VEGF-A; it also binds to placental growth factor and VEGF-B. A 12-week treatment cycle may be possible (3)[B].
- No FDA-approved stem cell therapies for macular degeneration exist.

**SURGERY/OTHER PROCEDURES**

- Laser treatment for CNVMs located ≥200 microns from the center of the macula has been evaluated in the Macular Photocoagulation Study (MPS).
  - Anti-VEGF treatment is first-line therapy for subfoveal CNVMs.
Vitrectomy has been used to remove CNVMs, but this is generally not recommended. CNVMs can bleed spontaneously, leaving blood underneath the retina. Vitrectomy to remove subretinal blood may be of benefit and should be performed within 7 days of the bleed. Tissue plasminogen activator (tPA) instilled into the eye may help remove a subretinal hemorrhage. In some cases, intravitreal gas with or without tPA may displace submacular blood:
- Intravitreal anti-VEGF monotherapy may be helpful in the treatment of neovascular ARMD associated with a submacular hemorrhage.
- Photodynamic therapy (PDT) with verteporfin is not frequently used anymore.
  - Patients should be informed of a <4% risk of acute, severe vision loss after PDT.
  - Ranibizumab has greater clinical efficacy than PDT.
  - Combination treatment with intravitreal ranibizumab and PDT appears to offer similar gain in visual acuity when compared with ranibizumab monotherapy.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Free radical formation in the retina, induced by visible light, may play a role in cellular damage that results in atrophic/nonexudative macular degeneration. The Age-Related Eye Disease Study (AREDS) found that a high-dose regimen of antioxidant vitamins and mineral supplements reduced progression of ARMD in some cases.
- Recommended daily doses: Vitamin C 500 mg, vitamin E 400 IU, β-carotene 15 mg, zinc oxide 80 mg, and cupric oxide 2 mg
  - Exercise caution with β-carotene use in smokers due to potential link to lung cancer.
- The AREDS2 found that the addition of lutein with zeaxanthin alone or in combination with omega-3 fatty acids had no overall effect in further reducing the risk of progression to advanced ARMD. The recommended daily doses: vitamin C 500 mg, vitamin E 400 IU, lutein 10 mg, zeaxanthin 2 mg, zinc 80 mg

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Amsler grid can aid in discovering visual disturbances.
- Patients with soft drusen or pigmented changes in the macula are at an increased risk of visual loss. They should monitor their vision, such as by daily Amsler grid testing, and subjective measures of visual acuity, such as reading ability; if no new symptoms, follow-up examination in 6 to 12 months

**DIET**
- Eating dark green, leafy vegetables (spinach/collard greens), which are rich in carotenoids, may decrease the risk of developing the neovascular/exudative stage.
- Fish consumption with omega-3 fatty acid intake may reduce the risk of ARMD.
- A Western-type diet characterized by higher intake of red meat, processed meat, high-fat dairy products, French fries, refined grains, and eggs increases the risk of ARMD as compared to an Oriental-type diet characterized by higher intake of vegetables, legumes, fruit, whole grains, tomatoes, and seafood, which decreases the risk of ARMD.
  - A Mediterranean diet may reduce the risk of developing ARMD.
**PROGNOSIS**

- Patients with bilateral soft drusen and pigmentary changes in the macula, but no evidence of exudation, have an increased likelihood of developing CNVMs and subsequent visual loss.
- Patients with bilateral drusen carry a cumulative risk of 14.7% over 5 years of suffering significant visual loss in one eye from the neovascular stage of ARMD.
- Patients with neovascular stage in one eye and drusen in the opposite eye are at an annual risk of 5–14% of developing the neovascular stage in the opposite eye with drusen.
- Macular atrophy progression and severity were the primary anatomic determinants of visual outcomes 7 years after treatment with ranibizumab.
- Attainment of good vision by the fourth injection of a VEGF inhibitor was strongly associated with 3-year visual outcomes (4)[B].
- Patients with exudative age-related macular degeneration with stable preoperative fluid on OCT generally do not have worsening of their neovascular process after cataract surgery (5)[C].

**COMPLICATIONS**

- Blindness
- The intraocular pressure should be monitored in eyes receiving intravitreal anti-VEGF injections.
  - Seven or more IVI of bevacizumab annually is associated with a higher risk of glaucoma surgery compared to less frequent administration (6)[B].

**REFERENCES**

**CODES**
ICD10
- H35.32 Exudative age-related macular degeneration
- H35.31 Nonexudative age-related macular degeneration
- H35.3190 Nonexudative age-related macular degeneration, unspecified eye, stage unspecified

CLINICAL PEARLS
- Patients may notice straight lines appear crooked (e.g., telephone poles).
- The ARED study found that a high-dose regimen of antioxidant vitamins and mineral supplements reduces progression of ARMD in some cases.
MALARIA
Kathrine R. Tan, MD, MPH • Francisca Abanyie-Bimbo, MD, MPH

BASICS

DESCRIPTION
- Infection with Plasmodium species protozoa, transmitted to humans by Anopheles spp. mosquitoes
- Most morbidity and mortality is caused by Plasmodium falciparum.
- Nonimmune individuals are most susceptible to rapid progression to severe disease.
- System(s) affected: cardiovascular, hematologic, renal, respiratory, cerebral, lymphatic, immunologic, hepatic

EPIDEMIOLOGY
- Cases imported to the United States: 68% P. falciparum; 12% Plasmodium vivax; 3% Plasmodium malariae; 5% Plasmodium ovale; 1% mixed; 11% unknown
- Occurs worldwide in tropical latitudes: P. falciparum, P. malariae, P. vivax, and P. ovale; Plasmodium knowlesi in parts of Southeast Asia
- Malaria is responsible for 1–3 million deaths/year (primarily children in sub-Saharan Africa)
- 300–500 million cases annually across the globe.
- Most prevalent in rural tropics (altitude below 1000 m)

Incidence
- Most U.S. cases (>99%) are imported.
- There are ~30 million travelers to tropical areas each year. 10,000–30,000 travelers from the U.S. and Europe contract malaria annually
- ~2,000 cases and 5 deaths per year in the U.S.

Prevalence
- Predominant age: all ages
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY
- Plasmodia are transmitted via saliva from infected Anopheles mosquito during a blood meal. Circulating plasmodia enter red blood cells (RBC), digest RBC proteins, and alter the RBC membrane, causing hemolysis, increased splenic clearance, and anemia.
- RBC lysis stimulates release of cytokines and tumor necrosis factor (TNF-α), causing fever and systemic symptoms.
- P. falciparum alters RBC viscosity, causing obstruction and end-organ ischemia.

Genetics
Unknown, but inherited conditions may affect disease severity and susceptibility (glucose-6-phosphate dehydrogenase [G6PD] deficiency, sickle cell disease or trait, Duffy-negative blood group, and hereditary elliptocytosis).

RISK FACTORS
- Travel to or migration from endemic areas
Rarely, blood transfusion, mother-to-fetus transmission, and local autochthonous transmission

GENERAL PREVENTION

- Mosquito avoidance: Use insect repellent, wear clothing to cover exposed skin, use mosquito nets treated with insecticides such as permethrin, and avoid outdoor activity from dusk to dawn (when feeding activity of Anopheles mosquito is the greatest).
- Malarial chemoprophylaxis in endemic areas
  - Atovaquone/proguanil: Begin 1 to 2 days before arrival and continue for 1 week after leaving area. Adults, 1 adult tablet daily; children 5 to 8 kg, 1/2 pediatric tablet daily; children 9 to 10 kg, 3/4 pediatric tablet daily; children >10 to 20 kg, 1 pediatric tablet daily; children >20 to 30 kg, 2 pediatric tablets daily; children >30 to 40 kg, 3 pediatric tablets daily; children >40 kg, 1 adult tablet daily
    - Caution: don’t use in pregnant women and infants <5 kg.
  - Chloroquine: Begin 1 to 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 500 mg salt (300-mg base) weekly; children, 8.3 mg/kg salt (5-mg base/kg) weekly up to 500 mg salt.
    - Caution: chloroquine-resistant areas, can make psoriasis worse.
  - Doxycycline: Begin 1 to 2 days before arrival and continue for 4 weeks after leaving area. Adults, 100 mg daily; children >8 years old, 2 mg/kg up to 100 mg daily
    - Caution: don’t use in pregnant women and children ≤ 8 years old.
  - Hydroxychloroquine sulfate: Begin 1 to 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 400 mg salt (310 mg base) weekly; children, 6.5 mg/kg salt (5 mg base/kg) weekly up to 400 mg salt.
    - Caution: chloroquine-resistant areas, can make psoriasis worse.
  - Mefloquine: Begin at least 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 250 mg (1 tablet) weekly; children ≤9 kg, 5 mg/kg weekly; children >9 to 19 kg, 1/4 tablet weekly; children >19 to 30 kg, 1/2 tablet weekly; children >30 to 45 kg, 3/4 tablet weekly; children >45 kg as adult dosing
    - Caution: mefloquine-resistant areas; don’t use if history of psychiatric disorders.
  - Primaquine: Begin 1 to 2 days before arrival and continue for 1 week after leaving area; adults, 30 mg/day; children, 0.5 mg/kg/day up to adult dose
    - For use only in areas predominantly endemic for P. vivax
    - Caution: Exclude G6PD deficiency prior to first use, do not use in pregnant women or breastfeeding women unless infant has been tested for G6PD deficiency.
  - Tafenoquine: Take daily 3 days before arrival, weekly during travel, and 1 week after leaving area; adults 200 mg per dose
    - Caution: Exclude G6PD deficiency prior to first use; don’t use if history of psychiatric disorders; don’t use in children; do not use in pregnant or breastfeeding women.

COMMONLY ASSOCIATED CONDITIONS

- Bacterial coinfections sometimes occur.
- Sickle cell trait confers an element of protection against malaria due to changes in the RBC cytoskeleton.

DIAGNOSIS
HISTORY

- Initial malaria symptoms are nonspecific. Suspect malaria in ill patients returning from an endemic area with:
  - Fever, malaise, myalgias, chills, headache, nausea, splenomegaly (with chronic infection), hypotension, anemia (with chronic or severe disease), thrombocytopenia, jaundice, vomiting, and/or diarrhea (resembling gastroenteritis)

- P. falciparum
  - Incubation usually 7 to 14 days, symptoms within 1 month of infection in most individuals (Partially immune individuals such as immigrants may become ill up to 1 year after last exposure.)
  - Severe disease and complications: vascular collapse, central nervous system impairment, renal failure, and acute respiratory distress syndrome

- P. vivax and P. ovale
  - Incubation period 9 to 18 days for primary infection and up to 12 months (and longer) for relapses; generally presents with fevers
  - Dormant parasites may remain in liver and reactivate years after initial infection.
  - Can be severe

- P. malariae
  - Incubation period 18 to 40 days
  - May become chronic; untreated can persist asymptptomatically in human host for years

- P. knowlesi
  - Incubation period 9 to 12 days
  - Possibly severe

PHYSICAL EXAM

- Often not specific
  - General: elevated temperature, fatigue, tachycardia, tachypnea, jaundice
  - Neurologic: change in mental status and motor–sensory findings (cerebral malaria)
  - Cardiopulmonary exam: hemodynamic stability and signs of vascular leak (effusion; pulmonary edema)
  - Skin exam: pallor, rash
  - Abdominal exam: organomegaly

DIFFERENTIAL DIAGNOSIS

- Infections (disseminated or localized): abscess, viral, gastroenteritis, typhoid/paratyphoid, other bacteremias, rickettsial disease, mycobacteria
- Collagen vascular disease
- Neoplasms (lymphoma, leukemia, other blood dyscrasias, other tropical causes of splenomegaly)
- Severe malaria infection may mimic hepatitis, pneumonia, meningitis, stroke, or sepsis.

DIAGNOSTIC TESTS & INTERPRETATION

- Malaria microscopy, thick and thin blood smears (1)[A]
  - Blood is spread on a slide in both a thick and thin preparation, stained with Giemsa smear, and examined under 100× oil immersion.
  - Thick smear used to evaluate for presence of parasite forms (rings, trophozoites, schizonts)
  - Thin smear used to determine species and quantify the percentage of RBCs that are infected
Rapid antigen testing: can detect the presence of malaria parasites within minutes.

Other tests: species-specific PCR; species confirmation by PCR is encouraged.

General laboratory findings (nonspecific)
- In uncomplicated infection
  - Elevated liver function tests and lactate dehydrogenase
  - Thrombocytopenia, anemia, and leukopenia

Note: A low to low-normal platelet count or a slightly high bilirubin should alert the clinician to the diagnosis after exposure in an endemic setting.

**Initial Tests (lab, imaging)**
- Complete blood count with differential and platelets
- Basic chemistry panel, including bilirubin
- Malaria thick and thin blood films (If negative, repeat q12–24h for at least three sets.)
- Imaging necessary only for respiratory disease (chest x-ray) or cerebral malaria (CT scan prior to lumbar puncture)

**Follow-Up Tests & Special Considerations**
Submit specimens from suspected or confirmed malaria cases to the CDC for diagnostic confirmation, speciation, and drug resistance surveillance.

**Test Interpretation**
- Microscopy: Results should include both species of malaria and percent of red cells infected to determine the most appropriate treatment regimen.
- Rapid diagnostic test: use as a preliminary determination of presence of malaria infection, not to determine species of malaria. Perform smears to confirm results, determine species, and quantify percentage of red cells infected.

---

### TREATMENT

**MEDICATION**

**First Line**
- PO therapy for uncomplicated chloroquine-resistant P. falciparum (most P. falciparum), chloroquine-resistant P. vivax (see “For uncomplicated chloroquine-sensitive P. vivax” below for additional treatment for dormant stage), or when species is unknown, the following regimens are recommended:
  - Artemether-lumefantrine (Coartem): Tablet contains 20 mg artemether and 120 mg lumefantrine. Treatment schedule is a total of 6 doses over 3 days. On day 1, the initial dose is given and then second dose is 8 hours later. On days 2 and 3, doses are given BID. Persons 5 to <15 kg: 1 tablet per dose; persons 15 to <25 kg: 2 tablets per dose; persons 25 to <35 kg: 3 tablets per dose; persons ≥35 kg: 4 tablets per dose. (Call 1-855-COARTEM to locate pharmacy with stock.)
    - Caution: not recommended in infants weighing <5 kg.
  - Atovaquone-proguanil (Malarone): adult tablet: 250 mg atovaquone and 100 mg proguanil. Pediatric tablet: 62.5 mg atovaquone and 25 mg proguanil. Adults: 4 adult tablets QD for 3 days. Children 5 to 8 kg: 2 pediatric tablets QD for 3 days; children >8 to 10 kg: 3 pediatric tablets QD for 3 days; children >10 to 20 kg: 1 adult tablet QD for 3 days; children >20 to
30 kg: 2 adult tablets QD for 3 days; children >30 to 40 kg: 3 adult tablets QD for 3 days; children >40 kg: 4 adult tablets QD for 3 days
- Caution: not recommended in pregnant women and infants <5 kg. However, may be used if other treatment options are not available or are not being tolerated, and the potential benefit is judged to outweigh the potential risks.
- Quinine sulfate plus doxycycline or clindamycin: adults: quinine sulfate 650 mg (salt) TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia). Doxycycline 100 mg BID for 7 days. Clindamycin 20 mg (base)/kg/day divided TID for 7 days; children: quinine sulfate 10 mg (salt)/kg TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia) plus clindamycin dosed as above or doxycycline 2.2 mg/kg po every 12 hours for 7 days for children >8 years old.
- Caution: doxycycline is not recommended in pregnant women and children ≤8 years old. However, may be used if other treatment options are not available or are not being tolerated, and the potential benefit is judged to outweigh the potential risks.
- Mefloquine: adults: 750 mg followed by 500 mg 8 hours later; children: 15 mg/kg followed by 10 mg/kg 8 hours later (max total dose: 1,250 mg)
- Caution: not recommended in persons who have acquired infections from Southeast Asia due to drug resistance.
- PO therapy for chloroquine-sensitive P. vivax, P. ovale, P. malariae, and chloroquine-sensitive P. falciparum (rare); in addition to the treatment regimens listed above, other options include:
  - Chloroquine: adults: 1 g (600-mg base) followed by 500 mg (300-mg base) at 6, 24, and 48 hours after first dose; children: 16.6 mg/kg (10-mg base/kg) on day 1 (max 1,000 mg [600-mg base]) and then 8.3 mg/kg (5-mg/kg base) at 6, 24, and 48 hours after first dose
  - Hydroxychloroquine sulfate: adult: 800 mg salt (620 mg base) followed by 400 mg salt (310 mg base) at 6, 24, and 48 hours after first dose; children: 13 mg/kg salt (10 mg base/kg) followed by 6.5 mg/kg salt (5 mg base/kg) at 6, 24, and 48 hours after first dose
  - For P. vivax or P. ovale, add primaquine or tafenoquine to treat dormant parasites:
    - Primaquine: adults: 30-mg base (52.6 mg salt) daily for 2 weeks; children: 0.6 mg base/kg/day for 2 weeks
      - Caution: Exclude G6PD deficiency prior to first use; do not use in pregnant women.
    - Tafenoquine: patients age >16; 300 mg single dose
      - Caution: Exclude G6PD deficiency prior to first use; do not use in pregnant women.
- Therapy for severe malaria
  - Clinical features defining severe malaria:
    - Impaired level of consciousness (LOC)
    - Respiratory distress, jaundice
    - Repeated convulsions, shock
    - Renal failure
  - Laboratory features:
    - Parasitemia >5%
    - Hypoglycemia
    - Acidosis (usually lactic acidosis)
- Parenteral therapy
  - Artesunate: adults and children ≥20 kg, 2.4 mg/kg per dose, in children <20 kg 3.0 mg/kg
per dose. Dose at 0, 12, 24, 48 hours.
- Contact CDC to request artemisin: 770-488-7100; http://www.cdc.gov/Malaria/
- Can administer oral medications such as artemether-lumefantrine, atovaquone-proguanil, or quinine (dose as above) before artemisin arrives. Give via nasogastric tube if patient is unable to tolerate orals.

**ISSUES FOR REFERRAL**
Infectious disease or tropical medicine consultation. Malaria is reportable: https://www.cdc.gov/malaria/report.html.

**ADDITIONAL THERAPIES**
None

**Pediatric Considerations**
- Children are particularly susceptible to severe disease.
- All children, even infants, should receive chemoprophylaxis if traveling to an endemic area.
- Malaria can resemble acute gastroenteritis in children.
- Children with severe disease are prone to hypoglycemia. Use IV fluids with glucose for maintenance and monitor blood glucose frequently.

**Pregnancy Considerations**
- Chloroquine is safe in the doses recommended for prevention and treatment of malaria. Mefloquine is safe in the doses recommended for prevention and treatment of malaria.
- Artemether-lumefantrine (Coartem) is safe in the 2nd and 3rd trimesters in the doses recommended for the treatment of malaria. There is some evidence for its safety in the 1st trimester.
- Atovaquone-proguanil (Malarone) has limited evidence for its safety in pregnant women; it has not been shown to cause birth defects or other problems in animal studies.
- No primaquine, tafenoquine, or tetracyclines should be used in pregnancy or lactation. Quinine should be used during pregnancy because benefit outweighs risk.

**SURGERY/OTHER PROCEDURES**
Rarely, splenectomy with splenic rupture.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
None.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient care for all cases of P. falciparum malaria. Hospitalize patients with severe illness, regardless of species; outpatient care for others.
- Follow up all treated as outpatient within 24 hours.
- Add glucose to maintenance IV fluids because of risk of hypoglycemia if unable to tolerate fluids by mouth.
- Observe for fluid excess, renal insufficiency (reduced urine output), and hypoglycemia.
- Discharge criteria: clinical improvement and ability to tolerate oral medications and fluids, with documented decreasing parasitemia levels.
ONGOING CARE

PATIENT EDUCATION
- Malaria chemoprophylaxis prior to travel
- Travel information may be obtained at the CDC travel Web site: http://www.cdc.gov/travel.

PROGNOSIS
Malaria infection (particularly P. falciparum) can carry a high mortality if untreated. If diagnosed early and treated appropriately, the prognosis is excellent.

COMPLICATIONS
- If not treated early: cerebral malaria, acute renal failure, respiratory distress syndrome, disseminated intravascular coagulation, and massive hemolysis with severe anemia
- Other complications: seizures, anuria, delirium, coma, dysentery, algid malaria, blackwater fever, hyperpyrexia
- P. malariae: Nephrotic syndrome may develop in patients with chronic infection.

REFERENCES

CODES

ICD10
- B51.9 Plasmodium vivax malaria without complication
- B50.9 Plasmodium falciparum malaria, unspecified
- B52 Plasmodium malariae malaria

CLINICAL PEARLS
- Test for malaria in travelers returning from endemic areas presenting with fever or flulike illness.
- Early identification and aggressive treatment of persons with malaria is essential.
- Consult CDC for appropriate chemoprophylaxis recommendations when traveling to endemic areas.
- Treat patients with clinical malaria with a different medication than what was used for chemoprophylaxis.
- P. falciparum malaria can be rapidly fatal; inpatient treatment is recommended.
MARIJUANA (CANNABIS) USE DISORDER
J.E. Lambrecht, MD, PharmD, FACP, FSHM ● Paul G. Millner, MD

BASICS

DESCRIPTION

- Marijuana use leading to clinically significant impairment or distress, manifested by two or more of the following symptoms within a 12-month period:
  - Consumption of larger amounts over a longer period of time than intended
  - Persistent desire or unsuccessful efforts to cut down or control amount used
  - Inordinate amount of time spent in activities is necessary to obtain, use, or recover from use.
  - Presence of craving for cannabis
  - Recurrent use resulting in failure to fulfill major role obligations at work, school, or home
  - Continued use despite having persistent or recurrent social or interpersonal problems due to cannabis use
  - Important social, occupational, or recreational activities are given up or reduced.
  - Recurrent use in physically hazardous situations
  - Use is continued despite knowledge of having a persistent physical or psychological problem caused or exacerbated by cannabis.
  - Tolerance defined by using increased amounts of cannabis to achieve the desired effect or intoxication or diminished effect with continued use of the same amount
  - Withdrawal occurs following cessation of prolonged use, and has at least 3 behavioral symptoms such as anxiety, restlessness, depression, irritability, insomnia, odd dreams, or physical symptoms such as tremors and/or decreased appetite
  - Legal problems are no longer a criteria. Dependence and abuse have been merged into a single category.

- According to Diagnostic and Statistical Manual of Mental Disorders, 5th edition, marijuana or cannabis use disorder is defined as being mild, moderate, or severe depending on how many symptoms are present. Mild: 2 to 3; moderate: 4 to 5; severe: 6+ (1)

EPIDEMIOLOGY

- Cannabis use disorder applies to a subset of marijuana users, ~20% lifetime marijuana users meet criteria for cannabis use disorder, 23% of these individuals meet severe use criteria
- Cannabis is the most widely used illicit psychoactive substance in the United States, with 15% of U.S. adults reporting use in the past year (2).
- In 2014, an estimated 22 million Americans, age >12 years, self-identified as current marijuana users
- Approximately 30% of students have used marijuana at the time of college entry (3).
- In the United States, 10% of marijuana users become daily users, 20–30% become weekly users.
- Younger users have a higher rate of addiction; 1 in 6 adolescents become addicted with repeated use.
- Marijuana use is increasing in pregnant women. with 7% of pregnant women aged 18 to 25
years reporting use in 2014

- In the United States, the legal landscape is changing rapidly. Many states have legalized marijuana in some form.
- Popular opinion has changed over time. In 1969, only 12% of people approved of legalizing marijuana. In 2015, 58% approved of legalization.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- There are two therapeutically active cannabinoids in marijuana, δ9-tetrahydrocannabinol (THC) and cannabidiol (CBD).
- THC is the psychoactive component responsible for marijuana’s analgesic, antiemetic, and intoxicating properties.
- Cannabidiol is the nonpsychoactive component responsible for marijuana’s antianxiety, antidepressant, antipsychotic, antispastic, anticonvulsant, and antineoplastic properties.
- THC concentrations in marijuana have risen to an average of 6% (3).
- Smoking marijuana results in 25–50% absorption of THC, which rapidly passes into the circulation. The oral bioavailability of THC is much less (3–10%).
- Effects of smoked marijuana occur within minutes and last several hours.
- Effects from marijuana consumed in foods or beverages appear after 30 minutes to 1 hour and can last up to 4 hours.
- 12% of frequent users experience withdrawal.
- Use in men is reported at 3.5% and women 1.7%; females have a faster transition from use to cannabis use disorder (4).

**RISK FACTORS**

- Young individuals, especially 18 to 29 year olds, are at more risk for severe cannabis use disorder (4).
- Cigarette smokers are at higher risk for cannabis use disorder compared to nonsmokers.
- Higher potency marijuana increases risk of cannabis use disorder and increases severity of symptoms (5).
- Marijuana use is an independent risk factor for heart failure (6).
- Family history of chemical dependence
- Comorbid psychiatric disorders (i.e., antisocial personality disorder)
- Other substance use (i.e., alcohol, tobacco)
- Lower educational achievement (rates of dependence are lowest among college graduates)
- Low socioeconomic status
- Ease of acquisition of marijuana

**DIAGNOSIS**

- Significant impairment or distress results from use (1)[A].
- Screen for marijuana (similar to tobacco and alcohol).
- Ask for frequency and amount used (e.g., “How often do you use marijuana? Daily? Weekly?”; “How long does a typical ‘eighth’ [1/8 oz] last?”).
- Usage is defined by: occasional = 1/8 oz/week, moderate = 1/4 oz/week, heavy = 1/2 oz/week. (1 oz = 28.5 g, which is equivalent to about 50 to 60 cigarettes)
- Unexplained deterioration in school or work performance is a red flag for abuse.
- Problems with, or changes in, social relationships (e.g., spending more time alone or with
persons suspected of using drugs) and recreational activities (e.g., giving up activities that were once pleasurable) may also indicate abuse.

- If possible, obtain information from concerned parents or significant others.

**HISTORY**

- Clinical presentation of acute intoxication:
  - Euphoria, elation, laughter, heightened sensory perception, altered perception of time, increased appetite
  - Poor short-term memory, concentration
  - Fatigue, depression
  - Occasionally, distrust, fear, anxiety, panic
  - With large doses, acute psychosis: delusions, hallucinations, loss of sense of identity (7)
- Withdrawal symptoms include:
  - Irritability
  - Anxiety
  - restlessness
  - Nausea
  - Weight loss
  - Decreased appetite
  - Insomnia
  - Depressed mood
  - Tremors

**PHYSICAL EXAM**

- Evaluate for:
  - Conjunctival injection
  - Xerostomia
  - Nystagmus
  - Increased heart rate
  - Decreased coordination
  - Altered mental status
- Withdrawal findings (nonspecific, similar to other drugs of abuse) include:
  - Restlessness/agitation
  - Irritability
  - Tremor
  - Diaphoresis
  - Increased body temperature

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urine drug screen.
- Cannabinoids can be detected in urine weeks to months after marijuana use. Blood testing is preferred for interpreting acute effects and levels. In the United States, there is no consensus for acceptable legal limits for marijuana levels while driving. Hair testing can be unreliable and may reflect secondhand exposure. In general, testing identifies cannabis use (not necessarily cannabis use disorder).
TREATMENT

Currently, there are no specific treatment guidelines for cannabis use disorder. No intervention has proved consistently effective for marijuana abuse. Users often have a hard time quitting (1)[A].

Behavioral interventions include:
- Cognitive-behavioral therapy
- Motivational interviewing
- Contingency management
- Social network behavior therapy
- 12-step approach
- Family-oriented therapy
- Brief intervention
- Relapse prevention
- Community reinforcement approach

Cognitive-behavioral therapy and contingency management show better outcomes for reducing use and maintaining abstinence.

The addition of a comprehensive parenting training curriculum does not further enhance efficacy.

Treating comorbid behavioral health disorders may help reduce use, particularly among heavy users.

To help manage withdrawal:
- Reduce amount used before quitting entirely.
- Delay first use of marijuana until later in the day.
- Consider nicotine replacement therapy if concomitant tobacco use is present.
- Avoid cues and triggers associated with use.

Prescribe short-term analgesia and sedation for withdrawal symptoms, if required.

With marked irritability and restlessness, consider very-low-dose diazepam for 3 to 4 days.

Provide user and family members with information regarding abuse and withdrawal to increase understanding of abuse and reduce likelihood of relapse.

Withdrawal symptoms peak on day 2 or 3; generally subside by day 7. Vivid dreams can continue for 2 to 3 weeks.

MEDICATION

No effective medication currently exists to treat marijuana abuse.

Oral THC may help abate marijuana withdrawal in individuals who are trying to quit.

Medications used to treat other drug use disorders, such as buspirone, lithium, and fluoxetine, may have therapeutic benefit.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Monitor cessation by testing urine over several weeks for the inactive cannabis metabolites (carboxy-THC).

Drug screening of heavy smokers may remain positive for marijuana up to 6 weeks after last
PATIENT EDUCATION

National Institute on Drug Abuse (NIDA):
- http://www.drugabuse.gov
- https://drugpubs.drugabuse.gov/promotions/back-to-school
- http://www.drugabuse.gov/drugs-abuse/marijuana
- https://teens.drugabuse.gov/

COMPLICATIONS

Acute adverse effects
- Acute panic or paranoid reactions can occur, especially in drug-naive individuals or those with a history of psychosis or other behavioral health conditions.
- Psychotic symptoms with high doses
- Driving under the influence of marijuana increases the risk for motor vehicle accidents.
- Chronic adverse effects: abnormal brain development; diminished lifetime achievement
- Chronic bronchitis and impaired respiratory function in regular smokers
- Smoking marijuana is harmful in transplant patients and other immunosuppressed individuals (increased risk of inhaled aspergillosis and other infections).
- Marijuana use is associated with an increased risk of fibrosis in hepatitis C patients.
- Marijuana may contribute to or result in pancreatitis.
- Psychotic symptoms in heavy users, especially those with a personal or family history of schizophrenia
- Marijuana use increases the risk for addiction to other substances.
- An increased risk of heart failure, hypertension, ischemic stroke, and overall mortality in heavy cannabis users (6)
- Cannabinoid hyperemesis syndrome is characterized by episodes of cyclic nausea and vomiting in association with chronic cannabis use.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- F12.10 Cannabis abuse, uncomplicated
- F12.20 Cannabis dependence, uncomplicated
- F12.288 Cannabis dependence with other cannabis-induced disorder

CLINICAL PEARLS

- Marijuana abuse may result in poor performance in school or work, legal problems, and family dysfunction.
- Effects of smoked marijuana have an almost immediate onset and can last 1 to 3 hours. Effects from foods or beverages containing marijuana appear later, usually in 30 minutes to 1 hour but can last up to 4 hours. Smoking marijuana delivers significantly more THC into the bloodstream than through oral consumption.
- Acute marijuana intoxication is manifested by conjunctival injection, increased heart rate, euphoria, heightened sensory perception, altered perception of time, increased appetite, poor short-term memory and concentration, and fatigue. Large doses may result in acute psychosis, panic or paranoid reactions, delusions, or hallucinations.
- Withdrawal symptoms include weight loss, decreased appetite, insomnia, and depressed mood. These symptoms peak on day 2 or 3 and resolve by day 7.
- Cognitive-behavioral therapy, motivational interviewing, motivational enhancement therapy, and contingency management are four methods of behavioral-based interventions used to treat marijuana abuse.
MASTITIS
Montiel T. Rosenthal, MD  Melissa Christina Saab, MD, BS, BA

BASICS

DESCRIPTION
- Mastitis is an inflammation of the breast parenchyma and possibly associated tissues (areola, nipple, subcutaneous [SC] fat).
- Usually associated with bacterial infection (and milk stasis in the postpartum mother)
- Usually an acute condition but can become chronic cystic mastitis

EPIDEMIOLOGY
- Predominantly affects females
- Mostly in the puerperium; epidemic form rare in the age of reduced hospital stays for mothers and newborns
- Neonatal form
- Posttraumatic: ornamental nipple piercing increases risk of transmission of bacteria to deeper breast structures: Staphylococcus aureus is the predominant organism.

Incidence
- 3–20% of breastfeeding mothers develop nonepidemic mastitis.
- Greatest incidence among breastfeeding mothers 2 to 6 weeks postpartum
- Neonatal form occurs at 1 to 5 weeks of age, with equal gender risk and unilateral presentation.
- Pediatric form
- Around or after puberty
- 82% of cases in girls

ETIOLOGY AND PATHOPHYSIOLOGY
- Microabscesses along milk ducts and surrounding tissues
- Inflammatory cell infiltration of breast parenchyma and surrounding tissues
- Nonpuerperal (infectious)
  - S. aureus, Bacteroides sp., Peptostreptococcus, Staphylococcus (coagulase neg.), Enterococcus faecalis
  - Histoplasma capsulatum
  - Salmonella enterica
  - Rare case of Actinomyces europaeus
- Puerperal (infectious)
  - Staphylococcus aureus, Streptococcus pyogenes (group A or B), Corynebacterium sp., Bacteroides sp., Staphylococcus (coagulase neg.), Escherichia coli, Salmonella sp.
  - Methicillin-resistant S. aureus (MRSA)
- Rare secondary site for tuberculosis in endemic areas (1% of mastitis cases in these areas): single breast nodule with mastalgia
- Tuberculosis mastitis in non-endemic areas has also been reported in patients with exposure to TNF-alpha inhibitors and other immunomodulating compounds (1)[C].
- Corynebacterium sp. associated with greater risk for development of chronic cystic mastitis
- Granulomatous mastitis
– Idiopathic
  o Predilection for Asian and Hispanic women
  o Association with α₁-antitrypsin deficiency, hyperprolactinemia with galactorrhea, oral contraceptive use, Corynebacterium sp. infection, and breast trauma
  o Most women have a history of lactation in previous 5 years.
  o New cases have been reported in male-to-female transgender patients in setting of exogenous progesterone and estrogen treatment (2)[B].
– Lupus; autoimmune
• Puerperal
  – Retrograde migration of surface bacteria up milk ducts
  – Bacterial migration from nipple fissures to breast lymphatics
  – Secondary monilial infection in the face of recurrent mastitis or diabetes
  – Seeding from mother to neonate in cyclical fashion
• Nonpuerperal
  – Ductal ectasia
  – Breast carcinoma
  – Inflammatory cysts
  – Chronic recurring SC or subareolar infections
  – Parasitic infections: Echinococcus; filariasis; Guinea worm in endemic areas
  – Herpes simplex
  – Cat-scratch disease
• Lupus

RISK FACTORS
• Breastfeeding
• Milk stasis
  – Inadequate emptying of breast
  o Scarring of breast due to prior mastitis
  o Scarring due to previous breast surgery (breast reduction, biopsy, or partial mastectomy)
  – Breast engorgement: interruption of breastfeeding
• Nipple trauma increases risk of transmission of bacteria to deeper breast structures: S. aureus predominant organism
• Neonatal colonization with epidemic Staphylococcus
• Neonatal
  – Bottle-fed babies
  – Manual expression of “witch’s milk”
  – Can predispose to lethal necrotizing fasciitis
• Maternal diabetes
• Maternal HIV
• Maternal vitamin A deficiency (in animal models)
• Smoking

GENERAL PREVENTION
Regular emptying of both breasts and nipple care to prevent fissures when breastfeeding; also good hygiene including hand washing and washing breast pumps after each use

COMMONLY ASSOCIATED CONDITIONS
Breast abscess

**DIAGNOSIS**
- Fever >38.5°C and malaise
- Nausea ± vomiting
- Localized breast tenderness, heat, swelling, and redness
- Possible breast mass

**HISTORY**
- Breast pain
- “Hot cords burning in chest wall”
- Consider yeast infection if nipple pain and burning and/or infant with thrush.

**PHYSICAL EXAM**
- Breast tenderness
- Localized breast induration, redness, and warmth
- Peau d’orange appearance to overlying skin

**DIFFERENTIAL DIAGNOSIS**
- Abscess (bacterial, idiopathic granulomatous mastitis, fungal, tuberculosis)
- Tumor
  - Idiopathic granulomatous mastitis
  - Inflammatory breast cancer
  - Wegener granulomatosis
  - Sarcoidosis
  - Foreign body granuloma
  - Vasospasm (may be presentation for Raynaud)
- Ductal cyst (ductal ectasia)
- Consider monilial infection in lactating mother, especially if mastitis is recurrent.
- Mondor disease: thrombophlebitis of the superficial veins of the breast and anterior chest wall

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Mastitis is typically a clinical diagnosis. Labs rarely needed. In those ill enough to need hospitalization, consider the following:
- CBC
- Blood culture
- In epidemic puerperal mastitis
  - Milk leukocyte count
  - Milk culture
  - Neonatal nasal culture
- No imaging required for postpartum mastitis in a breastfeeding mother that responds to antibiotic therapy
- Mammography for women with nonpuerperal mastitis
- Breast ultrasound to rule out abscess formation in women
  - Special consideration for this in women with breast implants who have mastitis
Follow-Up Tests & Special Considerations
Lactating mothers produce salty milk from affected side (higher Na and Cl concentrations) as compared with unaffected side. Consider breast milk culture if suspect MRSA. Also consider testing for tuberculosis as may be initial presentation.

Diagnostic Procedures/Other
Options if further progression to abscess formation
- Needle aspiration
- Incision and drainage
- Excisional biopsy
- Ultrasound (US)-guided core needle biopsy is diagnostic method of choice for idiopathic granulomatous mastitis

TREATMENT

A Cochrane review found that insufficient evidence exists to confirm or refute the effectiveness of antibiotic therapy for the treatment of lactational mastitis (3)[A]. If present <24 hours and symptoms are mild, conservative management with milk removal and supportive measures is recommended.

MEDICATION
- Prioritized on the basis of likelihood of MRSA as etiologic factor and clinical severity of condition
- Treat for 10 to 14 days.
- For idiopathic granulomatous mastitis and localized infection, usually resolves with antibiotics and drainage

First Line
- Outpatient
  - Effective milk removal is most important management step
  - Dicloxacillin 500 mg QID
  - Cephalexin 500 mg QID
  - Trimethoprim/sulfamethoxazole (TMP/SMX); DS BID (If mastitis not improving within 48 hours after starting first-line treatment, consider MRSA.)
  - Lactobacillus fermentum or Lactobacillus salivarius 9 log 10 CFU/day
- Inpatient
  - Nafcillin 2 g q4h
  - Oxacillin 2 g q4h
  - Vancomycin 1 g q12h (MRSA possible)
- Breastfeeding beyond 1 month
  - Penicillin, ampicillin, or erythromycin
- If idiopathic granulomatous mastitis, consider corticosteroids ± methotrexate; surgical excision reserved for refractory cases (4)[C]
- May consider mycophenolate mofetil in patient refractory to treatment with antibiotics, steroids, and methotrexate (5)[C]

Pediatric Considerations
TMP/SMX given to breastfeeding mothers with mastitis can potentiate jaundice for neonates.

Second Line
- If mastitis is odoriferous and localized under areola, add metronidazole 500 mg TID IV or PO.
- If yeast is suspected in recurrent mastitis, add topical and oral nystatin.

ISSUES FOR REFERRAL
- Abscess formation
- Need for breast biopsy

ADDITIONAL THERAPIES
- Warm packs to improve blood flow and milk letdown and/or ice packs to reduce inflammation to affected breast for comfort
- The use of a breast pump may aid in breast emptying, especially if the infant is unable to assist in doing this.
- Wear supporting bra that is not too tight.

SURGERY/OTHER PROCEDURES
In cases of biopsy-proven idiopathic granulomatous mastitis, surgical removal can result in a 5–50% chance of recurrence, fistula formation, and poor wound healing.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- If a new mother is admitted to the hospital for treatment of her mastitis, rooming-in of the infant with the mother is mandatory so that breastfeeding can continue. In some hospitals, rooming-in may require hospital admission of the infant.
- Admission criteria/initial stabilization
  - Failure of outpatient/oral therapy
    - Patient unable to tolerate oral therapy
    - Patient noncompliant with oral therapy
    - Severe illness without adequate supportive care at home
  - Neonatal mastitis
  - Antibiotics
  - Frequent emptying of breasts, if breastfeeding
  - Analgesics for pain
    - Ibuprofen
    - Acetaminophen
- Breastfeeding/pumping of breasts encouraged
- Start infant with feedings on affected side.
- Abscess drainage is not a contraindication for breastfeeding.
- Massage in direction from blocked area toward nipple.
- Positioning infant at breast with chin or nose pointing to blockage will help drain affected area.
- Discharge criteria
  - Afebrile
  - Tolerating oral antibiotics well

ONGOING CARE
DIET
- Encourage oral fluids.
- Multivitamin, including vitamin A

PATIENT EDUCATION
- Encourage oral fluids.
- Rest is essential.
- Regular emptying of both breasts with breastfeeding
- Nipple care to prevent fissures

PROGNOSIS
- Puerperal
  - Good with prompt (within 24 hours of symptom onset) antibiotic treatment and breast emptying; 96% success rate
  - 11% risk of abscess if left untreated with antibiotics
  - Antibodies develop in breast glands within first few days of infection, which may provide protection against infection or reinfection.
- Rare risk of abscess formation beyond 6 weeks postpartum if no recurrent mastitis
- Idiopathic granulomatous mastitis recurrence rates high, encourage close follow-up

COMPLICATIONS
- Breast abscess 3% of women with puerperal mastitis
- Recurrent mastitis with resumption of breastfeeding or with breastfeeding after next pregnancy
- Bacteremia
- Sepsis

Algorithms: Breast Discharge; Breast Pain

CODES

ICD10
- N61 Inflammatory disorders of breast
- O91.22 Nonpurulent mastitis associated with the puerperium
- O91.23 Nonpurulent mastitis associated with lactation

CLINICAL PEARLS
- Complete emptying of the breasts on a regular schedule, avoiding constrictive clothing or bras that might obstruct breast ducts. Meticulous attention to nipple care, “adequate rest,” and a liberal intake of oral fluids for the mother can all reduce the risk of a breastfeeding mother’s developing mastitis.
- First-line treatment for puerperal mastitis is dicloxacillin 500 mg PO QID for 10 to 14 days. Most mastitis can be treated with oral therapy.
- Among breastfeeding mothers, if the symptoms of mastitis fail to resolve within several days of appropriate management, including antibiotics, further investigations may be required to confirm resistant bacteria, abscess formation, an underlying mass, or inflammatory or ductal carcinoma.
- More than two recurrences of mastitis in the same location or with associated axillary lymphadenopathy warrant evaluation with US or mammography to rule out an underlying mass.
**MASTOIDITIS**
Megan Finneran, MS, DO ● Emilio Nardone, MD

**BASICS**
Mastoiditis is an inflammatory process of the mastoid bone. It is most commonly a complication of acute otitis media (AOM).

**DESCRIPTION**
- Clinical manifestations of mastoiditis typically appear days to weeks after the first middle ear symptoms.
- Acute mastoiditis: symptoms <1 month in duration.
- Subdivided according to the pathologic stages:
  - Acute mastoiditis with periostitis (incipient mastoiditis): purulent material in the mastoid cavities
  - Coalescent mastoiditis (acute mastoid osteitis): destruction of the thin bony septae between air cells; followed by the formation of abscess cavities with pus dissecting into adjacent areas
- Masked mastoiditis (subacute mastoiditis): low grade, persistent infection with destruction of the bony septae between air cells; occurs in patients with persistent middle ear effusion or recurrent episodes of inadequately treated AOM
- Chronic mastoiditis: associated with failed treatment of chronic otitis media. Often associated with cholesteatoma; symptoms last months to years

**EPIDEMIOLOGY**
Highest incidence in children <2 years
- Similar to population susceptible to AOM (male, daycare attendance)
- Less common if immunizations up-to-date and antibiotics used to treat suppurative AOM

**Incidence**
1 to 2 cases per 100,000 children per year in U.S. (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Subclinical stage begins with AOM and inflammation of mastoid air cells
- Mastoid is part of petrous temporal bone composed of air-filled cells
- Mastoid aditus and antrum form a narrow connection between middle ear and mastoid air cells
  - Fluid in the middle ear can cause obstruction at aditus or antrum, blocking outflow tract of mastoid air cells
  - Edema and accumulation of purulent material most commonly spreads from mastoid air cells to periosteum via mastoid emissary veins with penetration of periosteum (acute mastoiditis with periostitis) (1)
- Increased pressure from fluid within the air cells leads to destruction of bony septae (acute mastoid osteitis/acute coalescent mastoiditis)
- Acute mastoid osteitis can spread to adjacent areas in head and neck with abscess formation:
  - Subperiosteal abscess (most common complication), Bezold abscess, suppurative labyrinthitis, suppurative central nervous system (CNS) complications
- AOM: Streptococcus pneumoniae, nontypeable Haemophilus influenzae
- Acute mastoiditis: Streptococcus pneumoniae (most common), group A streptococci/Streptococcus pyogenes, Staphylococcus aureus (including methicillin-resistant S. aureus [MRSA]), Haemophilus influenzae, Fusobacterium necrophorum
- Chronic mastoiditis: Pseudomonas aeruginosa, S. aureus, anaerobic bacteria, polymicrobials (organisms present in external ear canal), rarely Mycobacterium tuberculosis
- Abscess: S. aureus, mycobacteria, Aspergillus
- Increased incidence of penicillin-resistant S. pneumoniae infections has gradually lead to higher incidence of mastoiditis as complication of AOM (2)

**Genetics**
No known genetic pattern

**RISK FACTORS**
- Cholesteatoma-appears as squamous pearl in anterosuperior area of middle ear near tympanic membrane (TM)
- Recurrent AOM or chronic suppurative otitis media
- Immunocompromised state

**GENERAL PREVENTION**
- Ensure appropriate vaccinations (particularly pneumococcal vaccine) are up-to-date.
- Referral to ear/nose/throat (ENT) for chronic otitis media
- Appropriate diagnosis and treatment of AOM; prevent recurrent AOM
  - Chemoprophylaxis for AOM is an area of active research. Consider in children with two episodes of AOM in first six months of life or in older children, three episodes in 6 months or four episodes in 1 year
  - Chemoprophylaxis not currently recommended by American Academy of Pediatrics due to concern for multidrug resistance.
- Wear ear plugs when swimming or showering to keep water out of the ears with AOM.
- Treat chronic eustachian tube dysfunction (pressure equalization tubes).
- Early diagnosis of cholesteatoma

**COMMONLY ASSOCIATED CONDITIONS**
Acute otitis media

**DIAGNOSIS**

**HISTORY**
- Most common symptoms in infancy
  - Lethargy/malaise/irritability
  - Fever
  - Poor feeding/decreased appetite
- Recent ear infection
- Otorrhea (drainage from an ear infection)
- Otalgia and/or pain on mastoid bone behind the ear
- Swelling or redness over mastoid
- Swelling of the ear lobe
- Headache
- Hearing loss
- Chronic: Persistent ear drainage, persistent ear pain
- Chronic: AOM nonresponsive to antibiotic
- Suspicion for mastoiditis increases when symptoms of AOM persist >2 weeks

**PHYSICAL EXAM**

- Acute:
  - Fever
  - Erythema, tenderness, and/or edema overlying mastoid (postauricular)
  - Palpable postauricular fluctuance (later finding): most commonly postauricular in children >1 year and above ear in children <1 year
  - Displaced pinna up and outward in children >1 year or down and outward in children <1 year (2)
  - Otoscopic exam: AOM present, may have perforation of TM with or without purulent discharge
- Chronic mastoiditis:
  - Persistent or intermittent mucopurulent drainage
  - Decreased hearing
  - May be painless from chronic process
  - Otoscopic exam: may have mucopurulent discharge, perforation of TM

**DIFFERENTIAL DIAGNOSIS**

- Scalp infection
- Mumps, parotitis
- Severe otitis externa
- Periauricular cellulitis
- Benign neoplasm: aneurysmal bone cyst, fibrous dysplasia
- Malignant neoplasm: acute lymphocytic leukemia, acute myelogenous leukemia, Burkitt lymphoma, non-Hodgkin lymphoma, rhabdomyosarcoma, neuroblastoma
- Deep neck space infections (2)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- CBC with differential: elevated WBC count
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) in acute but may be normal in chronic
- Blood cultures
- Myringotomy/tympanocentesis: send for cultures, Gram stain, acid-fast stain
- Aspiration if postauricular fluctuance is present: send for cultures
- Plain films of mastoid has low diagnostic yield but may show loss of sharpness of mastoid outline, clouding of mastoid air cells, or demineralization of bony septa (3). These changes are not diagnostic and can also be seen in AOM.
- Preferred: CT of the temporal bone (97% sensitivity; 94% positive predictive value for identifying intracranial complications) (4)
  - Clouding/opacification of air cells (also in AOM)
  - Mastoid air cell coalescence
– Cortical bone erosion
– Rim-enhancing fluid collections
– Absence of mastoid opacification excludes the diagnosis

**Use CT with contrast if complications are suspected (suppurative extension)**

**Due to radiation, CT in children should be performed when clinically appropriate. Indications include:**
– Neurologic signs
– Vomiting/lethargy
– Suspected cholesteatoma
– Fever after 48 to 72 hours of therapy

**Technetium-99m bone scan is more sensitive to osteolytic changes than CT**

**MRI: partial-to-complete opacification of the mastoid air cells ± middle ear cleft**
– Needed to evaluate for intracranial complications if clinical or radiographic suspicion

**Consider magnetic resonance angiography (MRA) if venous sinus thrombosis suspected.**

### Follow-Up Tests & Special Considerations

**Send all cultures for aerobic and anaerobic growth.**

**Interpret normal WBC with caution in symptomatic, immunocompromised patients.**

**One study found 23-fold increased risk of intracranial complication in children who had already received antibiotics for AOM and had CRP >93.5mg/L. Consider early imaging in these patients**

**If TM is ruptured, sample may be contaminated by colonizing ear canal flora.**

**Lumbar puncture if meningitis is suspected**

**Consider immunologic evaluations in children with recurrent episodes of OM leading to mastoiditis.**

### Diagnostic Procedures/Other

**Tympanocentesis to obtain middle ear fluid for culture and sensitivity**

**Myringotomy with culture (also therapeutic)**

**Audiography if suspected hearing loss**

**Obtain CSF if intracranial extension suspected.**

**Biopsy tissue protruding through TM or tympanostomy tube**

---

## TREATMENT

**IV antibiotics and myringotomy (± tympanostomy tubes) is the preferred treatment for uncomplicated acute mastoiditis (reflecting a shift away from more invasive surgical treatment).**

**To avoid intracranial complications, simple mastoidectomy is recommended if patients do not respond to treatment after 3 to 5 days.**

**Myringotomy or incision and drainage may be necessary if an abscess is present in mastoid air cells.**

### GENERAL MEASURES

Inpatient care during acute phase for IV antibiotics

### MEDICATION
First Line
- Empiric antibiotics against most common organisms: S. pneumoniae (including multiple resistant strains), S. pyogenes, S. aureus (including MRSA), P. aeruginosa
- Use combination therapy with 3rd-generation cephalosporin (ceftriaxone or cefotaxime) plus clindamycin with coverage for resistant strains.
- Ceftriaxone 2 g IV q24h
  - Pediatric dosing: 50 to 75 mg/kg/day IV divided q12–24h
  - Precaution: Adjust dose with renal impairment.
  - Consider levofloxacin 750 mg IV q24h if severe β-lactam allergy.
- Clindamycin for coverage of ceftriaxone-resistant S. pneumoniae in pediatric patients:
  - Clindamycin pediatric dosing: 20 to 40 mg/kg/day IV divided q6–8h
- Cefotaxime 1 to 2 g IV q4–8h, depending on severity
  - Pediatric dosing: 100 to 200 mg/kg/day q6–8h
- Add vancomycin 30 to 60 mg/kg/day divided q8–12h if concerned for MRSA or acute on chronic exacerbation:
  - Pediatric dosing: 15 mg/kg/dose q6–8h
  - Precaution: Adjust dose with renal impairment.
- For patients with a history of recurrent AOM or recent antibiotic administration, treat with piperacillin and tazobactam 3.375 g IV q6h:
  - Pediatric dosing: 300 mg/kg/day based on piperacillin component divided q6–8h
- Once culture results are available, use target treatment based on antibiotic sensitivities.

Second Line
- Oral antibiotics after 7 to 10 days of IV antibiotics and once myringotomy/blood cultures identify pathogen and sensitivities. Common oral antibiotics:
  - Amoxicillin-clavulanate (Augmentin) or clindamycin + 3rd-generation cephalosporin for 3 weeks or total treatment duration of 4 weeks or longer for intracranial complications (5)
- For chronic mastoiditis: Use topical drops, ofloxacin otic solution (0.3%) or neomycin, polymyxin B, hydrocortisone 3 drops, 3 to 4 times per day

ISSUES FOR REFERRAL
- Consult ENT for mastoiditis in adults and children.
- Consult neurosurgery for intracranial complications.
- Consider infectious disease consult for assistance with antibiotic management.

SURGERY/OTHER PROCEDURES
- Perform tympanocentesis to obtain cultures and guide antibiotic choice.
- Myringotomy and tympanostomy tubes allow for middle ear drainage.
- Clean ear canal under microscopic guidance to ensure pressure-equalization tube patency and adequate drainage of middle ear.
- Simple mastoidectomy is most effective for management of subperiosteal abscesses if a trial of conservative therapy with drainage, myringotomy, and IV antibiotics fails.

COMPLEMENTARY & ALTERNATIVE MEDICINE
No known home remedies

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
– Clinical or imaging evidence of acute mastoiditis
– Hospitalize patients with acute mastoiditis and start IV antibiotics immediately

• Avoid getting affected ear wet

• Discharge criteria
  – Afebrile for 48 hours before IV antibiotics are discontinued
  – Clinical improvement
  – Able to tolerate oral antibiotics

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

• Oral antibiotics for 3 weeks following course of IV antibiotics (total duration of antibiotics is 4 weeks or longer for intracranial complications)
• For chronic mastoiditis, consider several months of antimicrobial prophylaxis with amoxicillin.

Patient Monitoring

• Assess for hearing loss postoperatively (audiogram) after acute condition has subsided
• Follow-up with ENT and/or neurosurgery, particularly patients with hearing loss and/or intracranial complications

PATIENT EDUCATION

• Avoid getting the affected ear wet
• Complete full course of antibiotics

PROGNOSIS

• Depends on severity and stage of disease
• Most cases of mastoiditis recover fully if the diagnosis is made early and treated appropriately.
• Conductive hearing loss may require reconstructive surgery. Hearing loss may be permanent.

COMPLICATIONS

Complication rate 5–29% (5)

• Extracranial
  – Subperiosteal abscess (most common)
  – Bezold abscess (abscess of sternocleidomastoid muscle, insidious, risk of mediastinitis)
  – Citelli abscess (osteomyelitis of the calvaria)
  – Osteomyelitis of the temporal bone
  – Suppurative labyrinthitis
  – Permanent hearing loss
  – Facial nerve paralysis (2)

• Intracranial
  – Intracranial abscess: epidural/subdural/cerebral
  – Meningitis/cerebritis/perioistitis
  – Hearing loss
  – Otitis hydrocephalus: decreased venous drainage causes benign intracranial hypertension, manifesting as increased intracranial pressure, headache, papilledema, and sixth nerve palsy
  – Encephalitis
  – Brain abscess
Gradenigo syndrome (sixth nerve palsy, severe pain in distribution of fifth nerve, and suppurative OM) (2)
- Sigmoid sinus thrombophlebitis or thrombosis
- Lateral sinus thrombosis
- Central venous sinus thrombosis (3)

REFERENCES

ADDITIONAL READING

CODES
ICD10
- H70.90 Unspecified mastoiditis, unspecified ear
- H70.009 Acute mastoiditis without complications, unspecified ear
- H70.099 Acute mastoiditis with other complications, unspecified ear

CLINICAL PEARLS
- Suspect mastoiditis if symptoms of AOM persist >2 weeks despite a normal-appearing TM.
- Temporal bone CT is best diagnostic tool, use only when mastoiditis is suspected to limit radiation exposure in children.
- Hospitalize patients with acute mastoiditis for IV antibiotics. Consult ENT for drainage procedure.
• Treat with broad-spectrum IV antibiotics; collect middle ear fluid cultures to guide-specific therapy. Total duration of antibiotics is 4 weeks or longer for intracranial complications.
• If conservative treatment fails after 3 to 5 days, perform mastoidectomy to avoid intracranial complications.
MEASLES (RUBEOLA)
Wail Yar, MD, MPH • Jason Chao, MD, MS

BASICS
DESCRIPTION
- A highly communicable, acute viral illness characterized by an exanthematous maculopapular rash that begins at the head and spreads inferiorly to the trunk and extremities
- Rash is preceded by fever and the classic triad of cough, coryza, and conjunctivitis (3 Cs). Koplik spots are pathognomonic lesions of the oral mucosa early in the course of the infection.
- Public health problem in the developing world, with significant morbidity and mortality; rising incidence in developed nations with declining vaccination rates
- One dose of MMR vaccine is 93% effective, and 2 doses are 97% effective against measles.
- System(s) affected: hematologic; lymphatic; immunologic; pulmonary; skin
- Synonym(s): rubeola

EPIDEMIOLOGY
- Transmission: direct contact with infectious droplets; highly contagious; 90% of nonimmune close contacts likely to become infected on exposure
  - Droplets can remain in the air for hours
- Infectivity is greatest during the prodromal phase
  - Patients are considered contagious from 4 days before symptoms until 4 days after rash appears
  - Immunocompromised patients are considered contagious for the entire duration of disease
- Incubation period: averages 12.5 days from exposure to onset of prodromal symptoms
- Predominant age: varies based on local vaccine practices and disease incidence. In developing countries, most cases occur in children <2 years.

Incidence
- No longer considered an endemic disease in the United States; isolated outbreaks still occur.
- As of September of 2019, 1,241 cases of measles were reported to the Centers for Disease Control and Prevention (CDC) since the beginning of 2019. This is the greatest number of cases in the US since 1992. Most of these cases were linked to outbreaks in New York.
- Most recent outbreaks in the US occurred among unvaccinated US residents who traveled internationally (1).
- Worldwide: An estimated 20 million measles cases occur each year, with 117,000 measles deaths in 2017. >95% of measles deaths occur in impoverished countries with limited health infrastructure (2).

ETIOLOGY AND PATHOPHYSIOLOGY
Measles virus enters through the respiratory mucosa and replicates locally. It spreads to regional lymphatic tissues and other reticuloendothelial sites via the bloodstream.
- Measles virus is a spherical, enveloped, nonsegmented, single-stranded, negative-sense RNA virus of genus Morbillivirus, family Paramyxoviridae
- Humans are the only natural host
RISK FACTORS
- For developing measles:
  - Lack of adequate vaccination (2 doses)
  - Travel to countries where measles is endemic
  - Contact with exposed individuals
- For severe measles or measles complications:
  - Immunodeficiency
  - Malnutrition
  - Pregnancy
  - Vitamin A deficiency
  - Age <5 years or >20 years

GENERAL PREVENTION
- 100% preventable with proper vaccination
- Measles vaccine (active immunization)
  - Vaccine is usually given in combination with MMR or with added varicella (MMRV; ProQuad).
  - Primary vaccination requires 2 doses
    - First dose at 12 to 15 months of age; 95% develop immunity
    - Second dose at time of school entry (4 to 6 years of age) or any time >4 weeks after first measles vaccine; the 5% of initial nonresponders almost always develop immunity after the second dose.
    - Health care workers should have immunity verified and, if not immune, should receive the vaccine if not contraindicated.
  - Common adverse reactions to vaccine
    - Fever
    - Febrile seizures are rare (<5%) and occur 6 to 12 days after vaccination. Risk of febrile seizures increases if initial immunization is delayed past age 15 months (3).
    - Transient, mild, measles-like rash 7 to 10 days after vaccination (2%, with decreasing incidence during second vaccination)
    - If hypersensitivity reaction occurs, test for immunity; if immune, second dose not needed.
    - There is no substantiated link between MMR vaccine and autism.
  - Contraindications
    - Live viral vaccines are contraindicated in immunosuppressed patients. For MMR, vaccinate asymptomatic HIV-infected children with adequate CD4 count.
    - Live vaccine is contraindicated in pregnancy (risk of fetal infection).
    - Anaphylactic reaction to gelatin or neomycin; consult allergist before vaccination.
    - Egg anaphylaxis is not a contraindication.

COMMONLY ASSOCIATED CONDITIONS
- Immunosuppression
- Malnutrition

DIAGNOSIS

HISTORY
Prodromal period: usually 2 to 3 days before rash (may be up to 8 days)
- Fever
  - May begin 8 to 12 days after exposure; can persist until 2 to 3 days after rash onset
  - Temperature often >102°F (39–40.5°C); can precipitate febrile seizures
  - Fever onset >3 days after rash suggests complicated course
- “3 Cs” triad: cough, coryza, and conjunctivitis
- Cough may persist for 2 weeks
- Prodromal symptoms typically intensify over 2 to 4 days, peaking on 1st day of rash before subsiding.
- Other symptoms: loose stools, malaise, irritability, photophobia (from iridocyclitis), sore throat, headache, and abdominal pain

PHYSICAL EXAM
- Koplik spots
  - Pathognomonic of prodromal measles
  - 2- to 3-mm, gray-white, raised lesions on erythematous base on buccal mucosa
  - Occur ~48 hours before measles exanthem
- Exanthematous rash (characteristic but not pathognomonic)
  - Maculopapular blanching rash
  - Begins at ears and hairline and spreads head to toe, reaching hips by day 2
  - Discrete erythematous patches become confluent over time, particularly on the upper body.
  - Clinical improvement usually occurs within 48 hours after rash appears.
  - Rash fades in 3 to 4 days changing to a brownish color, followed by fine desquamation.
- Lymphadenopathy and pharyngitis may be seen during exanthematous period.

DIFFERENTIAL DIAGNOSIS
- Drug eruptions
- Rubella
- Mycoplasma pneumoniae infection
- Infectious mononucleosis
- Parvovirus B19 infection, roseola
- Enteroviruses
- Rocky Mountain spotted fever, dengue
- Toxic shock syndrome
- Meningococccemia
- Kawasaki disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Obtain serum sample and throat (or nasopharyngeal) swab. Molecular testing of serum and respiratory specimens is the most accurate method to confirm measles infection; IgM assay and measles RNA by real-time polymerase chain reaction (RT-PCR)
- Measles virus–specific IgM assay from serum and saliva. Antibodies may be undetectable on 1st day of exanthem but are usually detectable by day 3.
  - Sensitivity: 77% within 72 hours of rash onset; 100% within 4 to 11 days after rash onset. If negative but rash lasts >72 hours, repeat.
  - IgM falls to undetectable levels 4 to 8 weeks after rash onset.
Measles virus–specific IgG may be undetectable up to 7 days after exanthem; levels peak 14 days after exanthem.
- A 4-fold increase in IgG titers 14 days after an initial titer that was measured at least 7 days after rash onset is confirmatory.

Viral cultures for measles are not usually performed.
Mild neutropenia is common.
Liver transaminases and pancreatic amylase may be elevated, particularly in adults.
Chest x-ray if concern for secondary pneumonia

**ALERT**
Report suspected measles cases to public health authorities

**TREATMENT**

**GENERAL MEASURES**
- Place all patients with measles in respiratory isolation until 4 days after onset of rash; immunocompromised patients should be isolated for duration of illness.
- Supportive therapy (i.e., antipyretics, antitussives, humidification, increased oral fluid consumption)

**MEDICATION**
- No approved antiviral therapy is available. Immunosuppressed children with severe measles have been treated with IV or aerosolized ribavirin. No controlled trial data exist; use is not FDA-approved.
- Vitamin A: World Health Organization recommends daily dosages for 2 consecutive days:
  - Children <6 months of age 50,000 IU
  - Children 6 to 12 months of age 100,000 IU
  - Children >12 months of age 200,000 IU
- Ribavirin
  - Measles virus is susceptible to ribavirin in vitro; data are limited.
  - In one randomized trial including 100 children with measles treated with ribavirin or supportive care, ribavirin group had a shorter duration of fever, constitutional symptoms, and length of hospitalization.
- Antibiotics
  - Reserve for patients with clinical signs of bacterial superinfection (pneumonia, purulent otitis, pharyngitis/tonsillitis) (4).
  - A small trial resulted in an 80% (number needed to treat [NNT] = 7) decrease in measles-associated pneumonia with prophylactic antibiotics; consider in patients with a high risk of complications.
- Outbreak control
  - A single case of measles constitutes an outbreak, and local health authorities should be reported with suspected or confirmed cases.
  - In the inpatient setting: measles is considered an airborne disease and appropriate precaution should be taken for 4 days after the onset of the rash.
  - Measles may remain active for 2 hours in the air.
  - Immunize contacts (individuals exposed or at risk of having been exposed) within 72 hours.
Monovalent vaccine may be given to infants 6 months to 1 year of age, but 2 further doses of vaccine after 12 months must be given for adequate immunization.

Monovalent or combination vaccine may be given to all measles-exposed susceptible individuals age >1 year if not contraindicated.

Individuals not immunized within 72 hours of exposure should be excluded from school, child care, and health care settings (social quarantine) until 2 weeks after onset of rash in last case of measles.

- Immunoglobulin therapy (passive immunity) for high-risk individuals exposed to measles for whom vaccine is inappropriate:
  - Children age <1 year (infants 6 to 12 months of age may receive MMR vaccine in place of immunoglobulin if given within 72 hours of exposure)
  - Pregnant women
  - Severe immunosuppression
  - Give IM immunoglobulin within 6 days of measles exposure; CDC recommends 0.25 mL/kg to maximum of 15 mL for infants and pregnant women; dose for immunocompromised is 0.5 mL/kg to a maximum of 15 mL.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Inpatient setting: airborne transmission precautions for 4 days after the onset of rash in otherwise healthy patients and for the duration of illness in immunocompromised patients
- Outpatient care is appropriate, except where complications develop (e.g., encephalitis, pneumonia).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Signs of complications needing close follow-up:
- Difficulty breathing or noisy breathing
- Changes in vision
- Changes in behavior, confusion
- Chest or abdominal pain

**PATIENT EDUCATION**

- Adhere to recommended immunization schedules.
- Avoid exposure, particularly to unimmunized children and adults, pregnant women, and immunocompromised persons, until 4 days after rash onset.
- Avoid contact with potential pathogens until respiratory symptoms resolve.
- CDC: measles: [www.cdc.gov/measles/about/index.html](http://www.cdc.gov/measles/about/index.html)

**PROGNOSIS**

- Typically self-limited; prognosis good
- About 3% of adults will develop pneumonia that will require hospitalization.
- High fatality rates may be seen among malnourished or immunocompromised children, particularly in developing countries.
- Pregnant women, immunocompromised patients, children under age of 5, and adults older than 20 are at the greatest risk of developing measles complications.
COMPLICATIONS

- GI complications: diarrhea (may lead to dehydration) is the most common complication.
- Otitis media (5–15%), which may lead to hearing loss
- Respiratory complications:
  - Bronchopneumonia (5–10%)
    - Accounts for most measles-related deaths
    - May be viral or bacterial
  - Interstitial pneumonitis (immunocompromised patients)
  - Laryngotracheobronchitis (“measles croup”): occurs in younger age group (<2 years)
- Neurologic complications
  - Febrile seizures
  - Acute disseminated encephalomyelitis with seizures and neurologic abnormalities (occurs in 1/1,000 cases): presents within 2 weeks of rash, probably an autoimmune response
  - Inclusion body encephalitis is rare but fatal in those with defective cellular immunity.
  - Subacute sclerosing panencephalitis
    - Rare degenerative central nervous system disease resulting from persistent measles infection following natural disease; usually fatal
    - Presents 5 to 15 years after infection
    - Most often in persons infected before age 2 years
- The immune response to measles infection paradoxically depresses response to non–measles-virus antigens, rendering individuals more susceptible to pneumonia and diarrhea.
- Ocular complications
  - Keratitis
    - Can lead to permanent scarring, blindness
  - Vitamin A deficiency predisposes to more severe keratitis and its complications.
- Cardiac complications include myocarditis and pericarditis.
- Secondary bacterial infections: Measles can cause systemic secondary infection especially in developing countries.
- Death: results from complications, mainly pneumonia, rather than the virus itself. CDC statistics show that for every 1,000 children who get measles, 1 or 2 will die.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- B05.9 Measles without complication
- B05.2 Measles complicated by pneumonia
- B05.89 Other measles complications

CLINICAL PEARLS
- There is no substantiated link between MMR vaccine and autism.
- A single case of measles constitutes an outbreak; report suspected measles cases to state or local health departments immediately.
- Immunization requires 2 doses: one at 12 to 15 months of age and one at school age (4 to 6 years of age).
- The clinical presentation of measles includes a prodrome of fever, cough, coryza, and conjunctivitis, followed by a descending maculopapular rash beginning on the face and progressing to the chest and lower body (centrifugal).
- Consider measles in the differential diagnosis of a febrile rash illness (especially in unvaccinated individuals with recent international travel).
- Measles-associated pneumonia is the most common cause of mortality.
MEASLES, GERMAN (RUBELLA)
Jeffrey M. Milch, DO  Cody D. Mead, DO

BASICS

DESCRIPTION
- A generally self-limited viral infection of children and adults characterized by a mild, maculopapular rash, lymphadenopathy, and slight fever. Complications in normal, immunocompetent populations are rare. Nonimmune women infected with rubella while pregnant may have devastating fetal effects.
- 25–50% of all rubella infections are asymptomatic (1,2)[A].
- System(s) affected: hematologic; nervous; pulmonary; exocrine; ophthalmologic; skeletal
- Synonym(s): German measles; 3-day measles

Pregnancy Considerations
- Pregnancy-associated rubella infection may lead to congenital rubella syndrome (CRS) with potentially devastating fetal outcomes. CRS most commonly manifests as sensorineural deafness, eye abnormalities, and/or congenital heart disease.
- CRS is present in up to 90% of fetuses exposed during the 1st trimester (2)[A].
- Screening pregnant women for rubella immunity and vaccinating nonimmune women is the most effective strategy to prevent CRS (2)[A].
- Although no case of vaccine-associated CRS has been reported, women should not become pregnant for at least 28 days after vaccination because vaccine-type virus can cross the placenta (2)[A].
- Polymerase chain reaction (PCR) determination of viral RNA in amniotic fluid and fetal blood sampling allow for rapid diagnosis of fetal infection after 15 weeks’ gestation (3)[B].

EPIDEMIOLOGY
- 50- to 70-nm RNA togavirus of genus Rubivirus (1)
- 13 genotypes have been identified (4).
- A live attenuated vaccine has been available in the United States since 1969. Primary use is to prevent CRS.
- Since 2004, all U.S. cases of rubella have been imported; most cases are inadequately immune travelers (1).
- Average incubation: 14 days; ranges 12 to 23 days
- Infectious period between 7 days before and 5 to 7 days after rash onset
- Transmitted primarily via respiratory droplets
- Most common in late winter and early spring
- Humans are only natural hosts (1).

Incidence
- U.S. incidence: <10/100,000 since 2001
- Declared eliminated (no endemic transmission for 12+ months) from the United States in 2004. However, primarily due to disease in international travelers, vaccine avoidance, and lack of routine pediatric care in migrant populations, cases are still reported annually.
- 667 cases from 27 states (a record number) reported to the Centers for Disease Control and
Prevention (CDC) in 2015
Still occurs in developing countries with 100,000 cases of CRS reported annually worldwide

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Virus invades the respiratory epithelium, replicates in nasopharynx and regional lymph nodes, and spreads hematogenously. Infected patients shed virus from the nasopharynx 3 to 8 days after inoculation. Shedding lasts 7 or more days after onset of rash.
- Disease typically progresses from a prodromal stage (1 to 5 days) to lymphadenopathy (5 to 10 days) to an exanthematous, pruritic, maculopapular rash. Petechiae on the soft palate (Forchheimer spots) may precede or accompany the rash. Rash starts on the face and spreads outward to the trunk and extremities, sparing the palms and soles (14 to 17 days after onset of prodromal symptoms). The rash typically lasts an average of 3 days.
- Rubella first described by German scientists in the early 1800s as a variant of measles or scarlet fever
- 1962 to 1965: global pandemic resulting in an estimated 12.5 million cases in the United States, with 2,000 cases of encephalitis; 11,250 cases of therapeutic or spontaneous abortions; 2,100 neonatal deaths; and 20,000 infants born with CRS (1)[A]

**Genetics**

Children with CRS and children with type 1 diabetes share a high frequency of HLA-DR3 histocompatibility Ag and a high prevalence of islet cell Ab.

**RISK FACTORS**

Inadequate immunization, inadequate immunity after prior vaccination, immunodeficiency states, immunosuppressive therapy, crowded living/working conditions, international travel (1)[A]

**GENERAL PREVENTION**

- Vaccination is the most effective preventive strategy.
- Available combined with mumps, measles, rubella (MMR) or with varicella (MMR-V).
  - Isolated rubella vaccine is not available in the United States.
  - Adults: 1- or 2-dose MMR vaccine schedule is recommended for those born after 1957. When 2 doses are used, each must be ≥28 days apart.
  - Pediatric: A 2-dose MMR vaccine schedule is recommended with the first dose given at ages 12 to 15 months; second dose recommended either at 4 to 6 years or at 11 to 12 years of age.
  - Special pediatric cases: In special circumstances (e.g., upcoming international travel), the second dose may be given prior to 4 years of age but no sooner than 28 days since the initial dose.
  - Children 6 to 11 months of age may also receive a single dose prior to international travel but should be revaccinated with full 2-dose schedule starting at 12 months of age.
  - Children with HIV should receive MMR vaccine at 12 months of age if no contraindications exist. In the event of an outbreak, immediate vaccination of infants 6 to 11 months old is recommended (2)[A].
  - Vaccination is recommended for nonimmune people in the following groups: prepubertal boys and girls, all women of reproductive age, college students, daycare personnel, health care workers, and military personnel.
- Contraindications to vaccine: pregnancy, immunodeficiency (except HIV infection), within 3
months of IVIG or blood administration, severe febrile illness, or hypersensitivity to vaccine components. Patients who receive rubella vaccine do not transmit rubella to others, although the virus can be isolated from the pharynx. Breastfeeding is not a contraindication to vaccination (1)[A].

- During outbreaks, serologic screening before vaccination is not recommended because rapid mass vaccination is needed to stop disease spread (2)[A].
- MMR vaccine is not associated with autism (4)[A], (5)[B].
- Children who receive the MMR-V vaccine have a 2-fold increase in risk of febrile seizures compared with those who receive MMR and varicella vaccines separately (5)[B].
- Routine rubella antibody (IgG) screening is recommended during pregnancy (4)[A].

### DIAGNOSIS

**Council of State and Territorial Epidemiologists (CSTE) case definition of rubella (1)[A]**

- **Clinical case definition**
  - Acute onset of pink, coalescent macules on the face spreading to the trunk and extremities, becoming discrete macules that become confluent over (on average) 3 days
  - Temperature >99°F (37.2°C; if measured)
  - Arthralgia or arthritis, lymphadenopathy, or conjunctivitis
- **Laboratory criteria for diagnosis**
  - Isolation of virus from throat or nasopharynx, serum, cerebrospinal fluid (CSF), urine, or cataracts (postmortem)
  - 4-fold rise in acute- and convalescent-phase titers of serum IgG Ab
  - Positive serologic test for IgM Ab
  - PCR positive for virus

### HISTORY

- Most cases of postnatal rubella are inadequately immunized travelers returning from endemic areas.
- Rubella spreads quickly if living in close quarters.
- Postnatal rubella: low-grade fever, lymphadenopathy (postcervical, occipital, and postauricular), sore throat, nausea, anorexia, arthritis, arthralgia, malaise. 25–50% are asymptomatic.
- CRS: parental concerns about hearing or vision impairment, jaundice, or developmental delay
- Deafness could be the only manifestation and may not be noticed until 2nd year of life (2).

### PHYSICAL EXAM

- Postnatal rubella: low-grade fever, lymphadenopathy (posterior auricular, occipital, posterior cervical), exanthem (mild, pink, discrete 1- to 4-mm maculopapular rash), soft palate petechiae (Forchheimer sign) (20%) (1)
- CRS: microcephaly, large anterior fontanelle, sensorineural hearing loss (58%), cataracts, glaucoma, microphthalmia, pigmentary retinopathy, purpuric (“blueberry muffin”) skin lesions, murmur (50%) consistent with patent ducstus arteriosus (PDA), hepatosplenomegaly, jaundice, cryptorchidism, inguinal hernia, radiolucent bone disease (2)

### DIFFERENTIAL DIAGNOSIS

- Postnatal rubella
- Measles virus (rubeola)
- Scarlet fever (strep A)
- Infectious mononucleosis
- Erythema infectiosum (parvovirus B19)
- Roseola infantum (i.e., exanthem subitum)
- Toxoplasmosis
- Drug eruptions
- Other exanthematous enteroviral infections

- Congenital rubella
  - Measles
  - Parvovirus B19
  - Human herpesvirus 6
  - Other exanthematous entero- or arboviruses

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Because 50% of cases are subclinical, laboratory testing to confirm the diagnosis is preferred (1,2)[A].
- Detection of wild-type virus is gold standard (1)[A].
- Enzyme immunoassay (EIA): preferred testing for IgM antibodies, which may not be detectable until 5 days after the onset of rash (1)[A]
- Hemagglutination inhibition (HAI) test: A 4-fold increase of IgG Ab levels from acute to convalescent phase is diagnostic for recent infection (1)[A].
- Latex agglutination (LA) test: sensitive and specific but dependent on experience of lab personnel (1)[A]
- Immunofluorescent antibody (IFA) assay: used for detection of viral IgG and IgM Ab (1)[A]
- Avidity test: not routinely used; use only in reference labs; distinguishes recent versus past infections (1)[A]

  Most rubella cases are virus positive on the day of the rash onset and remain positive for the next 7 to 10 days. Perform serum collection during this period. When testing for IgM, repeat collection may be necessary if sample taken before day 5. When testing for seroconversion, collect a second IgG sample 2 to 3 weeks after the first (acute to convalescent phase); IgG usually detectable 8 days after rash onset (1)[A]

- Virus may also be isolated from 1 week prior to 2 weeks after the onset of rash. Maximal viral shedding occurs up to day 4 after rash onset. Best results are from throat swab samples (1)[A].
- Epidemiologically, viral genotyping by reverse transcription (RT)-PCR helps determine the country of origin. Collect throat swabs 4 days after the rash onset and send to CDC (1)[A].
- Reserve viral cultures of CSF for suspected cases of CRS or rubella encephalitis (1)[A].
- If a pregnant female is exposed, amniotic fluid PCR or fetal blood sampling may be done at 15 weeks’ gestation for viral detection. Placental biopsy (less common) may be done at 12 weeks’ gestation. If positive, offer genetic counseling (1)[A].
- As the incidence of rubella decreases, the positive predictive value (PPV) of IgM results decreases. False-positive findings occur in patients with parvovirus B19, mononucleosis, and positive rheumatoid factor (1)[A].
- After reexposure, individuals with a low level of Ab (from past infection or prior vaccination) may acutely show a small rise in Ab levels. This is not associated with a high risk of contagion to others or fetal complications (1)[A].
Follow-Up Tests & Special Considerations
- Reporting is state dependent. Send samples to the CDC for genotyping. Report cases of CRS to the National Congenital Rubella Syndrome Registry (1,2)[A].
- Infants with CRS may shed virus up to 1 year; contact isolation precautions during all hospitalizations until child turns 1 year old (unless child has two negative throat cultures and urine specimens a month apart after 3 months of age) (2)[A].

TREATMENT
- Supportive for mild cases
- Isolate patients for 5 to 7 days after rash onset.
- Postnatal rubella: mild and self-limited; treat symptomatically. Hospitalize for complications: idiopathic thrombocytopenic purpura (ITP) or encephalitis (1)[A].
- CRS: supportive care unless neurologic or hemorrhagic complications develop; phototherapy may be indicated for jaundice; multidisciplinary management of long-term complications (2)[A]

MEDICATION
No specific therapy available for mild cases

First Line
- Age- and dose-appropriate antipyretics
- Nonsteroidal anti-inflammatory drugs can be used for arthritis and arthralgias in adults and infants age >6 months.
- IVIG can be given for severe thrombocytopenia; most cases, however, are self-limited.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Individuals immune to rubella through natural infection or vaccine may be reinfected when reexposed; such infection is usually asymptomatic and detectable only by serology. Those who have received the vaccine have lower measurable IgG levels than those who had the natural disease.
- In CRS, it is important to detect auditory and visual impairment early (2)[A].
- 2/3 of internationally adopted children have no written record of immunizations (4)[A].

PATIENT EDUCATION
http://www.cdc.gov/rubella/

PROGNOSIS
- Postnatal rubella: Complete recovery is typical.
- CRS
  - Varied and unpredictable spectrum, ranging from stillbirth to normal infancy/childhood (1,2)[A]
Detectable levels of IgG persist for years and then may decline (does not drop at the expected 2-fold dilution per month). By age 5 years, 20% have no detectable antibody (2) [A].

- IgM may not be detectable until 1 month after birth and may persist for 6 to 12 months (2) [A].

- Overall mortality (up to 10%) is greatest during first 6 months.
- 70% of encephalitis cases develop residual neurologic defects, including autistic syndrome.
- Prognosis is excellent if only minor congenital defects are present.

COMPLICATIONS

- Arthralgia/arthritis in up to 70% of women (6)
- Postinfectious encephalitis (1/5,000 cases)
- Thrombocytopenic purpura (1/3,000 cases)
- CRS: incidence dependent on trimester exposed
- Rubella vaccine may rarely cause encephalitis or ITP.
  - ITP is self-limited and is not a contraindication to vaccination.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- B06.9 Rubella without complication
- B06.00 Rubella with neurological complication, unspecified
- P35.0 Congenital rubella syndrome

**CLINICAL PEARLS**
- Rubella is typically a self-limited viral exanthem in children and adults.
- Congenital rubella syndrome (CRS) in nonimmune women may have devastating fetal effects.
- Immunization is the key prevention strategy.
MEDIAL TIBIAL STRESS SYNDROME (MTSS)/SHIN SPLINTS
Vasilios Chrisostomidis, DO

BASICS

DESCRIPTION
- The term medial tibial stress syndrome (MTSS) is currently preferred to “shin splints.” MTSS is aching pain along the inner edge of the tibial shaft that develops when the musculature and/or periosteum in the (lower) leg become irritated by repetitive activity. The condition is part of a continuum of stress-related injuries to the lower leg. MTSS does not encompass pain from ischemia (compartment syndrome) or stress fractures.
- Tendonitis/periostitis of the medial soleus muscles, anterior tibialis, and posterior tibialis muscles
- Synonyms: tibial stress reaction, anterior muscle syndrome, tibial periostitis, perimyositis, soleus syndrome, shin splints

EPIDEMIOLOGY

Incidence
Common, can account for between 5% and 35% of novice-running injuries; frequently occurs bilaterally (1)

Pediatric Considerations
MTSS may account for up to 31% of all overuse injuries in high school athletes.

ETIOLOGY AND PATHOPHYSIOLOGY
- Multifactorial anatomic and biomechanical factors
  - Overuse injuries causing or limited by
    o Microtrauma from repetitive motion leading to periosteal inflammation
    o Overpronation of the subtalar joint and tight gastrocnemius/soleus complex with increased eccentric loading of musculature inserting along the medial shin
    o Interosseous membrane pain
    o Periostitis
    o Tears of collagen fibers
    o Enthesopathy
  - Anatomic structures affected include:
    o Flexor hallucis longus
    o Tibialis anterior
    o Tibialis posterior
    o Soleus
    o Crural fascia
- Pathogenesis: theorized to be due to (i) calf muscle traction on periosteum and (ii) persistent repetitive loading on tibia, which leads to inadequate bone remodeling with subsequent tibial cortex changes and possible microfissures causing pain without evidence of fracture or ischemia
RISK FACTORS
- Intrinsic (personal) risk factors:
  - Greater ranges of internal and external (>65 degrees) hip rotation
  - Significant overpronation at the ankle
  - Imbalance of musculature of the ankle and foot (inversion/eversion misbalance)
  - Female gender
  - Lean calf girth
  - Femoral neck anteversion
  - Navicular drop
  - Genu varum
  - History of previous MTSS
- External (environmental) risk factors
  - Lack of physical fitness
  - Inexperienced runners—particularly those with rapid increases in mileage and inadequate prior conditioning
  - Excessive overuse or distance running, particularly on hard or inclined (crowned) surfaces
  - Prior injury
  - Equipment (shoe) failure
- Other risk factors
  - Elevated BMI
  - Lower bone mineral density
  - Tobacco use
- Those typically affected by MTSS include:
  - Runners
  - Military personnel—common in recruit/boot camp
  - Gymnasts, soccer and basketball players
  - Ballet dancers

GENERAL PREVENTION
- Proper technique for guided calf stretching and lower extremity strength training, although supplementary gastrocnemius and soleus stretching has no statistical significance in reducing risk of shin splints
- Rehabilitate prior injuries adequately.
- Other recommendations
  - Gait analysis and retraining, particularly for overpronation
  - Orthotic footwear inserts

COMMONLY ASSOCIATED CONDITIONS
- Rule out stress fracture and compartment syndrome.
- Pes planus (flat feet)

DIAGNOSIS
HISTORY
- Patients typically describe dull, sharp, or deep pain along the lower leg that is resolved with rest.
Patients are often able to run through the pain in early stages. Pain is commonly associated with exercise (also true with compartment syndrome), but in severe cases, pain may persist with rest.

**PHYSICAL EXAM**
- Tenderness to palpation is typically elicited along the posteromedial border of the middle-to-distal 3rd of the tibia.
- Pain with plantar flexion
- Preservation of neurovascular integrity via palpable distal pulses, intact sensation, reflexes, and muscular strength

**DIFFERENTIAL DIAGNOSIS**
- **Bone**
  - Tibial stress fractures
    - Typically, pain persists at rest or with weight-bearing activities.
    - Focal tenderness over the anterior tibia
    - Hopping on involved leg will reproduce pain (less likely with MTSS).
- **Muscle/soft tissue injury**
  - Strain, tear, tendinopathy
  - Muscle hernia
- **Fascial**
  - Chronic exertional compartment syndrome (2)[C]
    - Pain without direct tenderness on exam
    - Pain increases with exertion and resolves at rest.
    - Pain is described as cramping or squeezing.
    - Pain with possible weakness or paresthesias on exam
    - Intersosseous membrane tear
- **Nerve**
  - Spinal stenosis
  - Lumbar radiculopathy
  - Common peroneal nerve entrapment
- **Vascular**
  - DVT
  - Popliteal arterial entrapment
    - Rare but limb-threatening disease
    - History of intermittent unilateral claudication
    - MRI reveals compression of the artery by the medial head of the gastrocnemius muscle.
- **Infection**
  - Osteomyelitis
- **Malignancy**
  - Bone tumors

**DIAGNOSTIC TESTS & INTERPRETATION**
- Plain radiographs help rule out stress fractures if >2 weeks of symptoms (3).
- Bone scintigraphy
  - Diffuse linear vertical uptake in the posterior tibial cortex on the lateral view.
  - Stress fractures demonstrate a focal ovoid uptake.
High-resolution MRI reveals abnormal periosteal and bone marrow signals, which are useful for early discrimination of tibial stress fractures.

Increased pain and localized tenderness warrant further imaging with MRI due to concern for tibial stress fracture.

Exclude compartment syndrome using intracompartmental pressure testing.

**TREATMENT**

**GENERAL MEASURES**
- Activity modification with a gradual return to training based on improvement of symptoms
- Running on flat and firm surfaces can help minimize pain.
- Patients should maintain fitness with low-impact activities such as swimming and cycling.
- Continue activity modification until pain free on ambulation.

**MEDICATION**
- Analgesia with acetaminophen or other oral nonsteroidal anti-inflammatory agent
- Cryotherapy (ice massage) is also advised to relieve acute-phase symptoms (4)[C].

**ADDITIONAL THERAPIES**
- Calf stretch, peroneal stretch, TheraBand exercises, and eccentric calf raises may improve endurance and strength (5)[A].
- Compression stockings have been used to treat MTSS with mixed results.
- Structured running programs with warm-up exercises have not been demonstrated to reduce pain in young athletes (6)[B].
- CAM boot for people with significant pain with weight-bearing

**SURGERY/Others PROCEDURES**
- Surgical intervention includes a posterior medial fascial release in individuals with both
  - Severe limitation of physical activity and
  - Failure of 6 months of conservative treatment
  - Counsel patients that complete return of activity to sport may not be always achieved postoperatively. Surgical risks include infection and hematoma formation.
- Extracorporeal shock wave therapy (ESWT) may decrease recovery time when added to a running program (5)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Individualized polyurethane orthoses may help chronic running injuries.
- Special insoles, low-energy laser treatment, pulsed electromagnetic field, and knee braces have not been shown to improve outcomes (5)[A].
- Ultrasound, acupuncture, aquatic therapy, electrical stimulation, whirlpool baths, cast immobilization, taping, and steroid injection may help improve pain.
- Physical therapy approaches including Kinesio tape and fascial distortion massage may yield quicker return to activity.
- Osteopathic manipulative treatment may yield quicker return to athletic activity as well.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Once well, recommend gradual return to preinjury running pace.
- Maintain stretching and strengthening exercises.
- Identify and correct preinjury training errors.
- Good supportive footwear is recommended as is replacing running shoes every 350 to 450 miles.
- Allow a gradual return to activity dictated by symptoms (pain).

PROGNOSIS
The condition is usually self-limiting, and most patients respond well with rest and nonsurgical intervention.

COMPLICATIONS
- Stress fractures and compartment syndrome
- Undiagnosed MTSS or chronic exertional compartment syndrome can lead to a complete fracture or tissue necrosis, respectively.

REFERENCES

ADDITIONAL READING
CODES

ICD10
- S86.899A Other injury of other muscle(s) and tendon(s) at lower leg level, unspecified leg, initial encounter
- S86.891A Other injury of other muscle(s) and tendon(s) at lower leg level, right leg, initial encounter
- S86.892A Other injury of other muscle(s) and tendon(s) at lower leg level, left leg, initial encounter

CLINICAL PEARLS
- MTSS is the preferred term for “shin splints.”
- Diagnosis is based on a reliable history of repetitive overuse accompanied by characteristic shin pain; imaging only if strong suspicion for stress fracture
- MTSS pain is typically along the middle and distal 3rd of the posteromedial tibial surface, worsened with activity and relieved with rest.
- Treatment includes ice, activity modification, analgesics, eccentric stretching, gait retraining, and a gradual return to activity.
- Symptoms recur if return to activity is “too much too fast.”
BASICS
Medical marijuana refers to the use of cannabis or cannabinoids as medical therapy to treat disease or alleviate symptoms.

DESCRIPTION
- Marijuana contains >100 phytocannabinoids.
- The most active ingredients include Δ-9-tetrahydrocannabinol (THC) and cannabidiol (CBD).
- Most of the psychoactive properties come from THC.
- Routes of administration include inhaled, intranasal, oral (extract, mixed into food, or made into tea), sublingual, and topical.
- Cannabinoids can be taken in herbal form, extracted naturally from the plant, gained by isomerization of CBD, or manufactured synthetically.

EPIDEMIOLOGY
- Cannabis is the most widely used illicit substance worldwide.
- An estimated 192 million people ages 15 to 64 years used cannabis in 2016.
- In the United States in 2016, 8.9% of individuals 12 years old had smoked cannabis in the previous month and 13.9% in the past year and 46% of 12- to 17-year-olds have used marijuana in 2016.
- Use among high school seniors now exceeds tobacco use and is commonly seen in lower socioeconomic groups.
- More than half of the states in the United States have legalized marijuana, although it remains illegal under federal law (schedule 1 substance).

Prevalence
Prevalence rates are higher in western USA.

RISK FACTORS
Cannabis use is more common in young unmarried males with poor socioeconomic status. Smokers and alcoholics have increased use of cannabis.

GENERAL PREVENTION
Education about the adverse effects of cannabinoids and overall education beyond high school can decrease use.

DIAGNOSIS
Diagnosis relies on careful history taking, collateral information from family and friends, as well as drug screening.

DIAGNOSTIC TESTS & INTERPRETATION
THC is lipophilic, thus can be detected in urine, blood, and hair for many days after use, while saliva tests can only detect THC for a few hours. While blood tests can only detect THC for 3–4 hours, urine tests can remain positive up to 30 days (1), depending on the type and frequency of use.

- Tests may be positive for about 3 days, after the initial use of marijuana.
- For those who smoke marijuana 3 or 4 times a week, the detection window increases to 5–7 days.
- Tests may be positive for 30 days or even longer in those who smoke daily.

**TREATMENT**

In order to qualify for medical marijuana in states where it is legal, patients have to fail first- and second-line therapies, including an FDA-approved cannabinoid, and cannot have a substance-use disorder, psychotic disorder, or unstable mood disorder.

**MEDICATION**

FDA-approved cannabinoids and indications

- **Dronabinol (Marinol):** capsule with synthetically derived THC dissolved in oil. Indications include:
  - Refractory chemotherapy-induced nausea and vomiting
  - Anorexia resulting in weight loss in patients with AIDS
- **Nabilone (Cesamet):** a capsule with synthetic cannabinoid that mimics THC
  - Indications above as dronabinol
  - Spasticity due to spinal cord injury
- **Nabiximols (Sativex):** an oromucosal spray containing THC and CBD in 1:1 ratio
  - Used for treating spasticity in multiple sclerosis (MS), cancer-related pain, and neuropathic pain

**Conditions**

- **Chronic pain (2) [B]**
  - May benefit in refractory pain, neuropathic pain, and pain associated with cancer. In a recent meta-analysis of 27 randomized trials, there is low-strength evidence that cannabis alleviates neuropathic pain but insufficient evidence in treating other types of pain.
  - Head-to-head studies have failed to show superiority to codeine or amitriptyline.
  - Dronabinol has been shown to have longer lasting pain reduction and fewer side effects than non–FDA-approved cannabinoids.
- **MS (3) [B]**
  - Spasticity: In a meta-analysis of 11 studies, cannabinoids improved spasticity, but effect did not reach statistical significance.
  - Pain: Oral cannabinoid extracts reduced pain in a small number of studies, but these results were limited by significant placebo effect and were also lacking statistical power.
  - Bladder dysfunction: no consistent evidence showing benefit
  - Tremor: Available data show probably ineffective.
  - Smoked marijuana has unclear efficacy and has been shown to negatively affect posture and balance.
  - Several studies showed an increase in cognitive impairment among MS patients who use cannabis. This occurred even in patients who used as infrequently as once per month.
Side effects of increased weakness, mood changes including suicidal ideation, dizziness, and fatigue were noted, which MS patients are already at risk of experiencing.

- **HIV/AIDS**
  - Low-quality evidence showed some weight gain on dronabinol, although the effect was similar to megestrol (2)[A].
  - Concern for exacerbation of HIV-associated cognitive deficits (4)[C]
  - Evidence of any long-term benefit and/or change in morbidity and mortality is lacking.

- **Post-traumatic stress disorder (PTSD) (5)[B]**
  - Conflicting data exist for the use of marijuana for PTSD. Most of these studies showed negative outcomes and worsening of PTSD symptoms.

- **Seizures (6)[B]**
  - Insufficient evidence per American Academy of Neurology
  - Best available meta-analysis includes only 48 patients in four studies. Included studies have multiple major flaws including no information on randomization, data reported only on side effects but not primary outcome. One study is an abstract only with no statistical analysis performed.
  - One study showed total seizure freedom compared to placebo group (two patients); all other studies showed no improvement.
  - Overall well tolerated, mild drowsiness noted in one study

- **Chemotherapy-induced nausea and vomiting**
  - Low-quality evidence suggests that cannabinoids are associated with improvements in nausea and vomiting due to chemotherapy (dronabinol and nabiximols) (4)[C].
  - Improvement was more noticeable for nausea than vomiting due to limitations of oral route of administration and length of time to peak plasma level.
  - Repeated use has been linked with increased nausea and vomiting in some patients.

- **Inflammation**
  - Cannabinoids induce apoptosis, inhibit cell proliferation, and suppress cytokine production.
  - Initial studies in animal models suggest possible benefit in rheumatoid arthritis and inflammatory bowel disease, but this research is in very preliminary stages.
  - A recent study in patients with MS failed to show any effect on disease progression.

- **Probably not effective**
  - **Acute pain**
  - **Glaucoma**
  - **Other neurologic conditions: tremor, Tourette syndrome, Huntington disease, and Parkinson disease**

---

**ONGOING CARE**

- **Side effects**
  - Dizziness, dry mouth, nausea, vomiting, fatigue, somnolence, disorientation, drowsiness, confusion, loss of balance, and hallucination
  - Acute psychological effects include euphoria, dysphoria, sedation, and altered perception.
  - Acute intoxication can cause tachycardia, hypertension, ataxia, paranoia, and psychosis.
  - Withdrawal syndrome can include symptoms of irritability, sleeping difficulties, dysphoria, craving marijuana, and anxiety.
ALERT
Overdose by children can cause respiratory depression. Several states with legalized marijuana have noted an increase in hospitalizations after accidental ingestion by children.

- **Long-term complications**
  - **Respiratory (4)[C]:**
    - Chronic bronchitis
    - Increased rates of respiratory infections and pneumonia
  - **Cardiovascular risk:**
    - Associated with hypertension, dyslipidemia, and increased caloric intake
    - 4.8-fold increase in incidence of myocardial infarction (MI) in 1st hour after use but became nonsignificant after 2nd hour
    - 4.2-fold increase in MI mortality rate for marijuana users versus nonusers
    - Several case reports of cerebrovascular events related to marijuana in patients with no other risk factors (17% increased risk among users)
    - Possible mechanisms include increased platelet coagulability, detrimental effects on microcirculation, and artery spasm.
  - **Cancer risk:**
    - Associated with increased incidence of lung cancer and upper airway/esophageal cancer; however, association disappeared when adjusted for cigarette smoking.
    - A recent review of six studies showed no association.
  - **Psychological (4)[C]:**
    - Increased anxiety, psychosis, and depression (noncausal association)
    - Increased risk of schizophrenia in early chronic users
    - Addiction occurs in 9% of all users, with higher rates among adolescents (17%) and daily users (20–25%).
    - Interference with cognitive function and short-term memory results in difficulty learning.
    - Increased motor vehicle accidents, relative risk (RR) = 2, compared to RR = 5 for blood alcohol level >.08
    - “Gateway drug” phenomenon persists even in states where marijuana use is legal.
      - Marijuana reduces dopamine activity in reward centers, increasing susceptibility to drug abuse.
      - Concurrent use primes brain for enhanced response to other drugs.
  - **Psychological (4)[C]:**
    - Increased anxiety, psychosis, and depression (noncausal association)
    - Increased risk of schizophrenia in early chronic users
    - Addiction occurs in 9% of all users, with higher rates among adolescents (17%) and daily users (20–25%).
    - Interference with cognitive function and short-term memory results in difficulty learning.
    - Increased motor vehicle accidents, relative risk (RR) = 2, compared to RR = 5 for blood alcohol level >.08
    - “Gateway drug” phenomenon persists even in states where marijuana use is legal.
      - Marijuana reduces dopamine activity in reward centers, increasing susceptibility to drug abuse.
      - Concurrent use primes brain for enhanced response to other drugs.
  - **Psychological (4)[C]:**
    - Increased anxiety, psychosis, and depression (noncausal association)
    - Increased risk of schizophrenia in early chronic users
    - Addiction occurs in 9% of all users, with higher rates among adolescents (17%) and daily users (20–25%).
    - Interference with cognitive function and short-term memory results in difficulty learning.
    - Increased motor vehicle accidents, relative risk (RR) = 2, compared to RR = 5 for blood alcohol level >.08
    - “Gateway drug” phenomenon persists even in states where marijuana use is legal.
      - Marijuana reduces dopamine activity in reward centers, increasing susceptibility to drug abuse.
      - Concurrent use primes brain for enhanced response to other drugs.

**Pediatric Considerations**
Adolescents have increased vulnerability to adverse long-term outcomes (4)[C].
- Brain endocannabinoid system actively develops during adolescence.
- Initial use during adolescence is associated with long-term brain changes:
  - Increased school drop out
  - Lower IQ
  - Diminished life satisfaction

**Pregnancy Considerations**
- Marijuana use is associated with decreased sperm count and reduced sperm motility.
- Studies show that cannabis reduces spermatogenesis by impairing hypothalamic-pituitary axis.
A study among Danish men between 18–28 years revealed that chronic use reduced the sperm count by 55%.
- Also thought to interfere with ovulation
- Chemicals produced by marijuana use are known to cross the placenta and into breast milk.
- Current evidence suggests that cannabis use during pregnancy and lactation may adversely affect neurodevelopment of fetal brain, with effects on neuropsychiatric, behavioral, and executive functioning.
- Three retrospective studies showed no adverse neonatal outcomes in cannabinoid users; however, may reduce lactation by inhibiting prolactin.
- Use is strongly discouraged because of concern for impact on fetal and infant neurocognitive development.

Areas of future consideration
- The risk of secondhand marijuana smoke exposure is unstudied.
- Increasing legal status contributes to public misconception of safety. The frequency of use and population health effects of recent changes in law should be carefully monitored.

REFERENCES

ADDITIONAL READING
CODES
ICD10
F12.90 Cannabis use, unspecified, uncomplicated

CLINICAL PEARLS

- There is scant robust clinical evidence supporting benefits of medical marijuana, and little to no evidence that alternate formulations have increased benefits compared to FDA-approved formulations.
- Medical marijuana has a narrow therapeutic index, with significant patient-to-patient variability in benefits and adverse effects.
- Chronic use in adolescents must be avoided due to the increased risk of long-term negative outcomes.
MELANOMA
Lloyd A. Runser, MD, MPH, FAAFP • Pratibha Sonam Vashista, DO

BASICS

DESCRIPTION

● Melanoma is a tumor arising from malignant transformation of pigment-containing cells called melanocytes, which are found in the stratum basale of the epidermis.
  – Most arise in the skin but may also present as a primary lesion in any tissue: ocular (uvea), GI, GU, lymph node, paranasal sinuses, nasal cavity, anorectal mucosa, and leptomeninges.
  – Extracutaneous sites have an adverse prognosis.
  – Metastatic spread to any site in the body

● Types of invasive cutaneous melanomas include:
  – Superficial-spreading melanoma: approximately 70% of cases; occurs in sun-exposed areas (trunk, back, and extremities); most <1 mm thick at diagnosis; when seen in younger patients, presents as a flat, slow growing, irregularly bordered lesion
  – Nodular: 15–30% of cases; present in older patients; tendency to ulcerate and hemorrhage; most commonly thick and pigmented; most common melanoma >2 mm
  – Lentigo maligna (subtype of melanoma in situ): slowest growing; older population; occurs in sun-exposed areas (head, neck, forearms) Lentigo maligna melanoma (LMM) is its invasive counterpart seen in 10–15% of cases; it is most commonly seen in elderly patients, most often in the head and neck regions.
  – Acral lentiginous: <5% of all melanomas; however, most common melanoma in black or Asian patients; found in palmar, plantar, and subungual areas; can mimic other skin abnormalities, including warts, calluses, tinea pedis, or ingrown toenails
    o An important subtype of acral lentiginous melanoma is subungal melanoma. From the nail matrix, presents as dark stripe under the nail plate; Hutchinson nail sign when brown or black pigment extends from the nail to the cuticle and proximal or lateral nail folds
  – Amelanotic melanoma: <5% of cases; can be missed and diagnosed at a later stage because it can mimic benign skin conditions, and thus is referred to as a “great pretender”
  – Desmoplastic melanoma: ~1% of cases; “neurotropic melanoma” or “spindled melanoma” with an abundance of fibrous tissue; demonstrates sarcoma-like tendencies with increased hematogenous spread; presents as a slow-growing lesion that is scar-like (no history of injury at the site is noted); often seen in the head and neck

● System(s) affected: skin/exocrine

Geriatric Considerations
Lentigo maligna is most common in elderly patients. This type is usually found on the face, beginning as a circumscribed macular patch of mottled pigmentation showing shades of dark brown, tan, or black.

Pediatric Considerations
Large congenital nevi (>5 cm) are risk factors and have a >2% lifetime risk of malignant conversion. Blistering sunburns in childhood significantly increase risk.

Pregnancy Considerations
No increased risk of melanoma in pregnancy. In the case of recent melanoma treatment, it is recommended to wait 1 to 2 years prior to becoming pregnant because melanoma can spread to the placenta.

**EPIDEMIOLOGY**

**Incidence**
- In 2019, 96,480 Americans are estimated to be newly diagnosed with melanoma, with approximately 7,230 expected deaths (1).
- Predominant age: median age at diagnosis 65 years (https://www.cancer.gov/); >50% of all individuals with melanoma are between 20 and 40 years of age.
- Predominant sex: male > female (1.5 times)
- Melanoma is >20 times more common in whites than in African Americans (1).
- Minority groups demonstrate increased rates of metastasis, advanced stages at diagnosis, thicker initial lesions, earlier age at diagnosis, and overall poorer outcomes.
- Low socioeconomic status associated with higher incidence of melanoma

**Prevalence**
- Melanoma is the fifth most common type of cancer in the United States
- Lifetime risk: men: 1/27; female: 1/40
- Lifetime risk in whites is ~2.6% (1/38), 0.1% (1/1,000) in blacks, and 0.58% (1/172) in Hispanics (1).
- 1.2% of all cancer deaths

**ETIOLOGY AND PATHOPHYSIOLOGY**
- DNA damage by UVA/UVB exposure
- Tumor progression: initially may be confined to epidermis with lateral growth, may then grow into dermis with vertical growth

**Genetics**
- Dysplastic nevus syndrome is a risk factor for development of melanoma. Close surveillance is warranted.
- 8–12% of patients with melanoma have a family history of disease.
- Mutations in BRAF (V600E) implicated in 50–60% of cutaneous melanomas
- Familial atypical mole malignant melanoma (FAMMM) syndrome characterized by >50 atypical moles, +FH of melanoma, clinical diagnosis (2)

**RISK FACTORS**
- Genetic predisposition, personal/family history of melanoma
- UVA and UVB exposure
- History of >5 sunburns during lifetime, blistering sunburns in childhood
- Previous pigmented lesions (especially dysplastic melanocytic nevi)
- Fair complexion, freckling, blue eyes, blond/red hair
- Highest predictor of risk is increased number of nevi (>50).
- 70% of melanomas are de novo, not existing from previous nevi (2)
- Tanning bed use: 75% increased risk if first exposure before age 35 years
- Changing nevus (see ABCDE criteria)
- Large (>5 cm) congenital nevi
- Chronic immunosuppression (chronic lymphocytic leukemia, non-Hodgkin lymphoma, AIDS,
or posttransplant)
- Living at high altitude (>700 meters or 2,300 feet above sea level)
- Occupational exposure to ionizing radiation

**GENERAL PREVENTION**
- Avoidance of sunburns, especially in childhood. Seek shade and avoid midday sun.
- Use of broad-spectrum sunscreen with at least SPF 30 to all skin exposed to sunlight reapplying regularly and after toweling or swimming
- Avoid tanning beds; class 1 carcinogen by World Health Organization (WHO)
- Screening of high-risk individuals, especially males >50 years
- Education for proper diagnosis plays a large factor in prevention.
- Any suspicious lesions should be biopsied with a narrow excision with 1- to 3-mm margins that encompass the entire breadth plus sufficient depth of the lesion. Options include elliptical excisions, punch, or deep shave biopsies.

**COMMONLY ASSOCIATED CONDITIONS**
- Dysplastic nevus syndrome
- >50 nevi. These individuals have higher lifetime risk of melanoma than the general population because 30% of all melanoma arise in preexisting nevi (3).
- Giant congenital nevus: 6% lifetime incidence of melanoma
- Xeroderma pigmentosum is a rare condition associated with an extremely high risk of skin cancers, including melanoma.
- Psoriasis after psoralen-UV-A (PUVA) therapy

**DIAGNOSIS**

**HISTORY**
- Change in a pigmented lesion: either hypo- or hyperpigmentation, bleeding, scaling, ulceration, or changes in size or texture
- Obtain family and personal history of melanoma or nonmelanoma skin cancer.
- Obtain social history including occupation, sunbathing, tanning, and other sun exposure.

**PHYSICAL EXAM**
- ABCDE: Asymmetry, Border irregularity, Color variegation (especially red, white, black, blue), Diameter >6 mm, Evolution over time
- Any new and/or changing nevus, bleeding/ulcerated
- Location on Caucasians is primarily back and lower leg; on African Americans, it is the hands, feet, and nails.
- May include mucosal surfaces (nasopharynx, conjunctiva)
- Individuals at high risk for melanoma should have careful ocular exam to assess for presence of melanoma in the iris and retina.

**DIFFERENTIAL DIAGNOSIS**
- Dysplastic and blue nevi
- Vascular skin tumor
- Pigmented actinic keratosis
- Traumatic hematoma
- Pigmented basal cell carcinomas, seborrheic keratoses, other changing nevi
- Common or atypical melanocytic nevi
- Lentigo
- Pyogenic granuloma

**DIAGNOSTIC TESTS & INTERPRETATION**
- Lactate dehydrogenase (LDH), chest/abdomen/pelvic CT with or without PET/CT at baseline and in monitoring progression in metastatic disease (stage IV); brain MRI if any central nervous system symptoms or physical findings (4)
- Imaging studies only helpful in detecting and evaluating for progression of metastatic disease

**Diagnostic Procedures/Other**
- Dermoscopy allows for magnification of lesions; evidence limited on utility (2)[C]
- Full-thickness excisional biopsy remains the gold standard for diagnosis. Any suspicious nevus should be excised, either by elliptical excision, punch biopsy, or a scoop shave (saucerization) biopsy. Avoid superficial shave of suspicious lesion. Goal for full-thickness excision with 1 to 3 mm margins. Orient excisional biopsy to optimize future treatment (4)[C].
- Sentinel lymph node biopsy, a staging procedure, remains an important factor for prognosis (4)[A].

**Test Interpretation**
- Nodular melanoma is primarily vertical growth, whereas the other three types are horizontal.
- An estimated 1/10,000 dysplastic nevi become melanoma annually.
- Immunohistochemical testing increases sensitivity of lymph node biopsies.
- Staging is based on the tumor-node-metastasis (TNM) criteria by current American Joint Committee on Cancer (AJCC) criteria, including:
  - (T) thickness (mm) and ulceration
  - (N) number of regional lymph nodes involved
  - (M) distant metastases and serum LDH

**TREATMENT**

**GENERAL MEASURES**
Full surgical excision of melanoma is the standard of care. See below for recommended surgical margins.

**MEDICATION**
- For stages I to III, surgical excision is curative in most cases; in patients with stage IV disease, systemic treatment with chemotherapy is recommended.
- Preferred regimens include the following (4)[A]:
  - Anti PD-1 monotherapy
    - Pembrolizumab (Keytruda)
    - Nivolumab (Opdivo)
    - Nivolumab with ipilimumab
  - Combo therapy demonstrated 61% response versus ipilimumab alone (5)[B].
- If BRAF V600 activating mutation is present, can opt for target therapy with combinations of:
  o Dabrafenib/trametinib
  o Vemurafenib/cobimetinib
  o Encorafenib/binimetinib
- Additional active regimens (e.g., dacarbazine [DTIC], temozolomide, paclitaxel, carmustine [BCNU], cisplatin, carboplatin, vinblastine) often limited to those who are not candidates to preferred regimens
- Imatinib (Gleevec) in tumors with c-KIT mutation
- Interferon-α as adjuvant therapy received FDA approval in 1995 (high dose) and 2011 (pegylated) to treat stage IIB to III melanoma; shown to improve 4-year relapse rate but no overall effect on survival; 1/3 of patients will discontinue due to toxicity (granulocytopenia, hepatotoxicity) (4)[B].

ISSUES FOR REFERRAL
- Consultation with oncologist for consideration of chemotherapeutic options
- Surgical specialties may be required based on the extent of nodal and/or metastatic disease, if present.

SURGERY/OTHER PROCEDURES
- Standard of care for melanoma includes early surgical excision with the following recommended margins (4)[A]:
  - In situ tumors: 0.5 to 1.0 cm margin
  - Thickness of ≤1 mm (T1): 1 cm margin
  - Thickness of 1.01 to 2.00 mm (T2): 1 to 2 cm margins
  - Thickness of 2–4 mm (T3): 2 cm margins
  - Thickness of >4 mm (T4): 2 cm margins
- Sentinel lymph node biopsy is indicated in patients with T1b, T2-, T3-, and T4-staged melanomas.
  - Not recommended in melanoma in situ or T1a
- Mohs micrographic surgery is being increasingly used for melanoma in situ, but in general, it is not considered a treatment modality for melanoma because it relies on frozen section technique.
- Radiotherapy can be used to treat lentigo maligna in addition to certain head and neck lesions.
- Palliative radiation therapy can be used with metastatic melanoma.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Molecular and mouse tumor model studies support role of topical silymarin (milk thistle derivative) in decreasing UV radiation–induced inflammation, oxidative stress, and carcinogenesis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Most monitoring and treatment completed in the outpatient setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
After diagnosis and treatment, close follow-up and skin protection (i.e., sunblock, UV protective clothing) are highly advised.

**Patient Monitoring**
- Routine screening clinical skin examination annually for all persons >40 years is controversial and without proven benefit.
- Total body photography and dermoscopy should be used for surveillance of skin lesions, most commonly used for patients with >5 atypical nevi.
- For patients with a history of cutaneous melanoma, National Comprehensive Cancer Network guidelines recommend screening every 3 to 12 months depending on recurrence risk (4)[C], with annual examinations if there is no disease progression for 5 years.
- Lab and imaging tests after diagnosis and treatment of stage I to II melanoma are low yield, have high false-positive rates, and are not recommended (4)[B].

**PATIENT EDUCATION**
- Teach all patients to perform regular full-body skin examinations looking for ABCDEs, especially those at high risk, or who have had melanoma.
- High-risk patients should perform monthly skin self-examinations and be taught to examine inaccessible areas.
- Patients with a history of melanoma or dysplastic nevus syndrome should have regular total body examinations by a dermatologist.

**PROGNOSIS**
- Breslow depth (thickness) in millimeters remains among strongest predictors of prognosis.
- Median age at death is 70 years.
- Highest survival seen in women <45 years of age at diagnosis
- Metastatic melanoma has an average survival of 6 to 9 months; 15–20% 5-year survival with current treatment
- Stages I and II, appropriately treated, have 20-year survival rates of 90% and 80%, respectively.

**COMPLICATIONS**
- Metastatic spread and subsequent death
- Often referred to as the “great imitator,” given that metastatic disease may present in a variety of ways
- Unsatisfactory cosmetic results

**REFERENCES**

SEE ALSO

Atypical Mole (Dysplastic Nevus) Syndrome

CODES

ICD10

- C43.9 Malignant melanoma of skin, unspecified
- C43.30 Malignant melanoma of unspecified part of face
- C43.4 Malignant melanoma of scalp and neck

CLINICAL PEARLS

- Remember that amelanotic melanomas exist; pigmentation is not required.
- 70% of melanomas are de novo, not from preexisting nevi. Still, any changing nevi should be biopsied, preferably utilizing an excisional method to ensure that complete margins are taken (2).
- The prognosis is excellent with early detection and treatment.
MÉNIÈRE DISEASE
Jason E. Cohn, DO  Nadir Ahmad, MD, FACS  Thomas C. Spalla, MD

BASICS

DESCRIPTION
- An inner ear (labyrinthine) disorder characterized by recurrent attacks of hearing loss, tinnitus, vertigo, and sensations of aural fullness due to an increase in the volume and pressure of the inner ear endolymph fluid (endolymphatic hydrops)
- Often unilateral initially; nearly half become bilateral over time.
- Severity and frequency of vertigo may diminish with time, but hearing loss is often progressive and/or fluctuating.
- Usually idiopathic (Ménière disease) but may be secondary to another condition causing endolymphatic hydrops (Ménière syndrome)
- System(s) affected: nervous
- Synonym(s): Ménière syndrome; endolymphatic hydrops

EPIDEMIOLOGY
- Predominant age of onset: 40 to 60 years
- Predominant gender: female > male (1.3:1)
- Race/ethnicity: white, Northern European > blacks

Incidence
Estimates 1 to 150/100,000 per year

Prevalence
Varies from 7.5 to >200/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Not fully understood; theories include increased pressure of the endolymph fluid due to increased fluid production or decreased resorption. This may be caused by endolymphatic sac pathology, abnormal development of the vestibular aqueduct, or inflammation caused by circulating immune complexes. Increased endolymph pressure may cause rupture of membranes and changes in endolymphatic ionic gradient.
- Ménière syndrome may be secondary to injury or other disorders (e.g., reduced middle ear pressure, allergy, endocrine disease, lipid disorders, vascular, viral, syphilis, autoimmune). Any disorder that could cause endolymphatic hydrops could be implicated in Ménière syndrome.

Genetics
Some families show increased incidence, but genetic and environmental influences are incompletely understood.

RISK FACTORS
May include
• Stress
• Allergy
• Increased salt intake
• Caffeine, alcohol, or nicotine
• Chronic exposure to loud noise
• Family history of Ménière
• Certain vascular abnormalities (including migraines)
• Certain viral exposures (especially herpes simplex virus [HSV])

GENERAL PREVENTION
Reduce known risk factors: stress; salt, alcohol, and caffeine intake; smoking; noise exposure; ototoxic drugs (e.g., aspirin, quinine, aminoglycosides).

COMMONLY ASSOCIATED CONDITIONS
• Anxiety (secondary to the disabling symptoms)
• Migraines
• Hyperprolactinemia
• Hypothyroidism

DIAGNOSIS
Diagnosis is clinical.

HISTORY
• Symptomatic episodes are typically spontaneous but may be preceded by an aura of increasing fullness in the ear and tinnitus. These may occur in clusters, with long periods of symptom-free remissions.
• Formal criteria for diagnosis from American Academy of Otolaryngology–Head and Neck Surgery:
  – At least two episodes of rotational-horizontal vertigo >20 minutes in duration
  – Tinnitus or aural fullness
  – Hearing loss: Low frequency (sensorineural) is confirmed by audiometric testing.
  – Other causes (e.g., acoustic neuroma) excluded
  – During severe attacks: pallor, sweating, nausea, vomiting, falling, prostration
  – Symptoms are exacerbated by motion.

PHYSICAL EXAM
• Physical exam rules out other conditions; no finding is unique to Ménière disease.
• Horizontal nystagmus may be seen during attacks.
• Otoscopy is typically normal.
• Triggering of attacks in the office with Dix–Hallpike maneuver suggests diagnosis of benign paroxysmal positional vertigo, not Ménière disease.

DIFFERENTIAL DIAGNOSIS
• Acoustic neuroma or other CNS tumor
• Syphilis
• Third window syndromes
• Endolymphatic sac tumor
Viral labyrinthitis
- Transient ischemic attack (TIA), migraine
- Vertebrobasilar disease
- Other labyrinthine disorders (e.g., Cogan syndrome, benign positional vertigo, temporal bone trauma)
- Diabetes or thyroid dysfunction
- Vestibular neuritis
- Medication side effects
- Otitis media
- Autoimmune inner ear disease
- Autosomal dominant sensorineural hearing loss

**DIAGNOSTIC TESTS & INTERPRETATION**
Testing is done to rule out other conditions but does not necessarily confirm or exclude Ménière disease.

**Initial Tests (lab, imaging)**
- Consider serologic tests specific for Treponema pallidum in at-risk populations.
- Thyroid, fasting blood sugar, and lipid studies
- Consider MRI to rule out acoustic neuroma or other CNS pathology, including tumor, aneurysm, and multiple sclerosis (MS).

**Diagnostic Procedures/Other**
- **Auditory**
  - Audiology using pure tone and speech to show low-frequency sensorineural (nerve) loss and impaired speech discrimination; usually shows low-frequency sensorineural hearing loss
  - Tuning fork tests (i.e., Weber and Rinne), ABR, or MRI to rule out acoustic neuroma
  - Electrocochleography may be useful to confirm etiology.
- **Vestibular**
  - Caloric testing: Reduced activity on either side is consistent with Ménière diagnosis but is not itself diagnostic.
  - Head-impulse testing (1)[C]

**Test Interpretation**
- Histologic temporal bone analysis (at autopsy); dilation of inner ear fluid system, neuroepithelial damage with hair cell loss, basement membrane thickening, and perivascular microvascular damage
- Cytochemical analysis can reveal altered AQP4 and AQP6 expression in the supporting cell, altered cochlin, and mitochondrial protein expression (2)[B].
- Familial Ménière disease has been associated with DTNA and FAM136A genes (3)[B].

**TREATMENT**
- Usually managed in outpatient setting
- A paucity of evidence-based guidelines exists; therefore, there is no gold standard treatment.
- Medications are primarily for symptomatic relief of vertigo and nausea.
During attacks, bed rest with eyes closed prevents falls. Attacks rarely last >4 hours.

**MEDICATION**

**First Line**
- Acute attack: Initial goal is stabilization and symptom relief; for severe episodes
  - Benzodiazepines (such as diazepam): decrease vertigo and anxiety
  - Antihistamines (meclizine/dimenhydrinate): decrease vertigo and nausea
  - Anticholinergics (transdermal scopolamine): reduce nausea and emesis associated with motion sickness
  - Antidopaminergic agents (metoclopramide, promethazine): decrease nausea, anxiety
  - Rehydration therapy and electrolyte replacement
  - Steroid taper for acute hearing loss
- Maintenance (goal is to prevent/reduce attacks)
  - Lifestyle changes (e.g., low-salt diet) are needed.
  - Diuretics may help reduce attacks by decreasing endolymphatic pressure and volume; there is insufficient evidence to recommend routine use:
    - Hydrochlorothiazide; hydrochlorothiazide/triamterene (Dyazide, Maxzide)
    - Acetazolamide (Diamox)
- Contraindications/warnings:
  - Atropine: cardiac disease, especially supraventricular tachycardia and other arrhythmias, prostatic enlargement
  - Scopolamine: children and elderly, prostatic enlargement
  - Diuretics: electrolyte abnormalities, renal disease
- Precautions:
  - Sedating drugs should be used with caution, particularly in the elderly. Patients are cautioned not to operate motor vehicles or machinery. Atropine and scopolamine should be used with particular caution.
  - Diuretics: Monitor electrolytes.
- Significant possible interactions: transdermal scopolamine: anticholinergics, antihistamines, tricyclic antidepressants, other

**Second Line**
- Steroids, both intratympanic and systemic (PO or IV), have been used for longer treatment of hearing loss:
  - Addition of prednisone 30 mg/day to diuretic treatment reduced severity and frequency of tinnitus and vertigo in one pilot study.
- In Europe, betahistine, a histamine agonist, is routinely used (unavailable in the United States). Other vasodilators, such as isosorbide dinitrate, niacin, and histamine, have also been used; evidence of their effectiveness is incomplete.
- Evidence is lacking for routine use of Famvir; may improve hearing more than balance
- Intratympanic gentamicin has shown to improve vertigo (4)[B].

**ISSUES FOR REFERRAL**
- Consider ear, nose, throat/neurology referral.
- Patients should have formal audiometry to confirm hearing loss.

**ADDITIONAL THERAPIES**
Application of intermittent pressures via a myringotomy using a Meniett device has been shown to relieve vertigo (5)B:
- Safe; requires a long-term tympanostomy tube
Vestibular rehabilitation may be beneficial for patients with persistent vestibular symptoms:
- Safe and effective for unilateral vestibular dysfunction

SURGERY/OTHER PROCEDURES
- Interventions that preserve hearing:
  - Endolymphatic sac surgery, either decompression or drainage of endolymph into mastoid or subarachnoid space
    o Less invasive; may decrease vertigo; may influence hearing/tinnitus
  - Endolymphatic sac surgery is effective in controlling vertigo in short- and long-term follow-up in at least 75% of patients with Ménière disease who failed medical therapy (6)A.
  - Vestibular nerve section (intracranial procedure)
    o More invasive
    o Decreases vertigo and preserves hearing
  - Tympanostomy tube: may decrease symptoms by decreasing the middle ear pressure
- Interventions for patients with no serviceable hearing:
  - Labyrinthectomy: very effective at controlling vertigo but causes deafness
  - Vestibular neurectomy
  - Endoscopic vestibular nerve section (7)B
  - Cochlear implantation

COMPLEMENTARY & ALTERNATIVE MEDICINE
Insufficient evidence to support effectiveness, but many integrative techniques have been tried, including the following:
- Acupuncture, acupressure, tai chi
- Niacin, bioflavonoids, Lipo-flavonoid, ginger, Ginkgo biloba, and other herbal supplements

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Due to the possibility of progressive hearing loss despite decrease in vertiginous attacks, it is important to monitor changes in hearing and to monitor for more serious underlying causes (e.g., acoustic neuroma).

DIET
- Diet is usually not a factor, unless attacks are brought on by certain foods.
- A low salt is often recommended but not proven effective in randomized controlled trials.

PROGNOSIS
- Alert patients about the nature of alternating attacks and remission.
- Between attacks, patient may be fully active but is often limited due to fear or lingering symptoms. This can be severely disabling.
50% resolve spontaneously within 2 to 3 years.  
Some cases last >20 years.  
Severity and frequency of attacks diminish, but hearing loss is often progressive.  
90% can be treated successfully with medication; 5–10% of patients require surgery for incapacitating vertigo.

COMPLICATIONS
Loss of hearing; injury during attack; inability to work

REFERENCES

SEE ALSO
- Hearing Loss; Labyrinthitis; Tinnitus
- Algorithm: Dizziness

CODES

ICD10
- H81.09 Meniere’s disease, unspecified ear
- H81.01 Meniere’s disease, right ear
- H81.02 Meniere’s disease, left ear

CLINICAL PEARLS
- Ménière disease is characterized by vertigo, hearing loss, and tinnitus +/- aural fullness.
- There is a wide differential diagnosis for Ménière disease; therefore, one must fully investigate symptoms.
- Multiple medical, surgical, and rehabilitative treatments are available to decrease the severity and frequency of attacks.
MENINGITIS, BACTERIAL
Felix B. Chang Cruz, MD, FAAMA, ABIHM

BASICS

DESCRIPTION
Life-threatening bacterial infection of the meninges

EPIDEMIOLOGY
- Predominant age: neonates, infants, and elderly
- Predominant sex: male = female

Incidence
Varies by age and pathogen
- 18–34 years 0.66 per 100,000
- 35–49 years 0.95 per 100,000
- 50–64 years 1.73 per 100,000
- ≥65 years 1.92 per 100,000
- Group B Streptococcus: 0.25/100,000
- Neisseria meningitidis: 0.19/100,000
- Haemophilus influenzae: 0.08/100,000
- Listeria monocytogenes: 0.05/100,000

Prevalence
15,000 to 25,000 cases occur annually in US.

ETIOLOGY AND PATHOPHYSIOLOGY
Bacterial infection causes inflammation of the meninges. Age and likely pathogens guide empiric antibiotic choice. Tailor therapy to culture results whenever possible:
- Community-acquired bacterial meningitis is most commonly due to S. pneumoniae (50%) and N. meningitidis (30%).
- Nosocomial or postsurgical meningitis occurs after manipulation of the CNS space allowing for entry of pathogens.
- Newborns (<2 months)
  - Group B Streptococcus
  - Escherichia coli
  - L. monocytogenes
- Infants and children
  - S. pneumoniae
  - N. meningitidis
  - H. influenzae
- Adolescents and young adults
  - N. meningitidis
  - S. pneumoniae
- Immunocompromised adults
  - S. pneumoniae, L. monocytogenes, gram-negative bacilli such as Pseudomonas aeruginosa
– Mixed bacterial infection in <1% of cases

Older adults
  – S. pneumoniae 50%
  – N. meningitidis 30%
  – L. monocytogenes 5%
  – 10% gram-negatives bacilli: E. coli, Klebsiella, Enterobacter, P. aeruginosa

**Genetics**
Some Native American populations appear to have genetic or acquired susceptibility to invasive disease.

**RISK FACTORS**
- Immunocompromised
- Alcoholism, diabetes, chronic disease
- Neurosurgical procedure/head injury
- Close living quarters
- Neonates: prematurity, low birth weight, premature rupture of membranes, maternal peripartum infection, and urinary tract abnormalities
- Abnormal communication between nasopharynx and subarachnoid space (congenital, trauma), dural fistula
- Parameningeal source: otitis, sinusitis, mastoiditis
- Trauma: skull fracture
- Adults age >65 years, immunocompromised patients, and pregnant women are at risk for listeriosis.
- Complement component deficiencies C3, C5 to C9, properdin, factor H, and factor D
- Functional or anatomic asplenia

**GENERAL PREVENTION**
- Consider CSF fistula in cases of recurrent meningitis.
- Aseptic techniques for head wounds or skull fractures
- Meningitis caused by H. influenzae type B has decreased 55% with routine vaccination.
- Conjugate vaccines against S. pneumoniae may reduce the burden of disease in childhood.
- Chemoprophylaxis for close contacts of meningococcal meningitis patients

**COMMONLY ASSOCIATED CONDITIONS**
Factors associated with a worse prognosis:
- Alcoholism, old age, infancy, diabetes mellitus, multiple myeloma, head trauma, seizures, immunocompromised
- Coma, sepsis, sinusitis

**DIAGNOSIS**

**HISTORY**
- Antecedent upper respiratory infection
- Fever, headache, vomiting, photophobia
- Seizures, confusion
- Nausea, rigors, sweats, weakness
● Elderly: subtle findings including confusion
● Infants: irritability, lethargy, poor feeding
● Altered mental status
● Food exposures (e.g., L. monocytogenes)

PHYSICAL EXAM
● The triad of fever, neck stiffness, and altered mental status has low sensitivity (44%).
● 95% of patients present with at least two of the following: headache, fever, neck stiffness, and altered mental status.
  – Meningismus
  – Focal neurologic deficits
  – Meningococcal rash: macular and erythematous at first, then petechial or purpuric
  – Purpura fulminans: more common with meningococcus
  – Papilledema
  – Kernig sign: resistance or pain with passive knee extension following 90-degree hip flexion in supine position
  – Late signs and symptoms: hemiparesis, stroke, cognitive impairment, coma, epilepsy, hearing loss, permanent visual impairment

DIFFERENTIAL DIAGNOSIS
● Bacteremia, sepsis, brain abscess
● Seizures, other nonbacterial meningitides
● Aseptic meningitis
● Inflammatory noninfectious: Behçet disease, systemic lupus erythematosus (SLE), sarcoidosis, migraine
● Stroke
● Viral meningitis
● Lyme disease
● Leptospirosis
● Subarachnoid hemorrhage
● Central nervous vasculitides

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Prompt lumbar puncture (1)[A]
  – Head CT first if focal neurologic findings, papilledema, or altered mentation
  – Typical CSF analysis: turbid
  – Adults
    o >500 cells/mL WBCs
    o Glucose <40 mg/dL
    o <2/3 blood-to-glucose ratio
    o CSF protein >200 mg/dL
    o CSF opening pressure >30 cm
    o Suspect ruptured brain abscess when WBC count is unusually high (>100,000).
● CSF Gram stain and cultures
Polymerase chain reaction (PCR) of CSF (particularly in suspected viral meningitis)
 Reserve bacterial antigen tests for cases where initial CSF Gram stain is negative and CSF culture is negative at 48 hours.
 Serum blood cultures, serum electrolytes
 Evaluate clotting function if petechiae or purpura is present.
 Chest radiograph may reveal pneumonitis or abscess.
 C-reactive protein (CRP): Normal CRP has high negative predictive value.
 Later in course, head CT if hydrocephalus, brain abscess, subdural effusions, and subdural empyema are suspected or if no clinical response after 48 hours of appropriate antibiotics
 Lactate concentration not recommended for suspected community-acquired bacterial meningitis.
 Elevated CSF protein concentration plus hypoglycorrhachia suggest ventriculitis or meningitis.

Follow-Up Tests & Special Considerations
Consider initiation of empiric antibiotics once the blood cultures are drawn if LP is delayed.

Diagnostic Procedures/Other
Lumbar puncture
 Noncontrast Head CT is recommended prior to LP to assess the risk of herniation if the patient is immunocompromised, has papilledema, a history of central nervous system disease, focal neurological deficit on exam, visual field cut, new-onset seizure 1 week or less prior to presentation or an abnormal level of consciousness.
 Lumbar puncture contraindications: signs of increased intracranial pressure (decerebrate posturing, papilledema), skin infection at site of lumbar puncture, CT or MRI evidence of obstructive hydrocephalus, cerebral edema, herniation
 Symptoms of infection plus positive CSF culture and CSF pleocytosis indicate ventriculitis or meningitis.

Test Interpretation
Bacterial Meningitis: Opening pressure > 180 mm H20; CSF protein, usually high; CSF glucose, usually low; Cell counts > 1 × 10^9/L.

TREATMENT

GENERAL MEASURES
 Initiate empiric antibiotic therapy immediately after lumbar puncture (lumbar puncture > Abx). If head CT scan is needed, initiate antibiotic therapy immediately after blood cultures (Abx > CT > lumbar puncture) (1)[A].
 Watch for seizures and aspiration precautions.

MEDICATION
Empiric antibiotic IV therapy (with dexamethasone for known or suspected S. pneumoniae meningitis) until culture results are available (1)[A]
 Consider local bacterial sensitivity patterns.

First Line
 Neonates
- Ampicillin: 150 mg/kg/day divided q8h and
- Cefotaxime: 150 mg/kg/day divided q8h
- Infants >4 weeks of age
  - Ceftriaxone: 100 mg/kg/day divided q12–24h or cefotaxime 225 to 300 mg/kg/day divided q6–8h and
  - Vancomycin: 60 mg/kg/day divided q6h

**Adults (1)[A]**
- Vancomycin loading dose 25 to 30 mg/kg IV and then 15 to 20 mg/kg q8–12h with goal trough of 15 to 20 and
  - Immunocompromised: Use vancomycin, ampicillin, ceftazidime, and acyclovir.
  - >50 years, add ampicillin: 2 g IV q4h for Listeria
  - Cefotaxime: 2 g IV q4–6h or
  - Ceftriaxone: 2 g IV q12h
- Precaution: aminoglycoside ototoxicity
- Penicillin-allergic patients
  - Chloramphenicol: 1 g IV q6h and
  - Vancomycin: loading dose 25 to 30 mg/kg IV and then 15 to 20 mg/kg q8–12h (goal trough of 15 to 20)

**Treatment duration**
- S. pneumoniae: 10 to 14 days
- N. meningitidis, H. influenzae: 7 to 10 days
- Group B Streptococcus organisms, E. coli, L. monocytogenes: 14 to 21 days
- Neonates: 12 to 21 days or at least 14 days after a repeated culture is sterile
- No reliable evidence to support the use of preadmission antibiotics for suspected cases of nonsevere meningococcal disease

**Corticosteroids (2)[A]**
- Pediatrics
  - Early treatment with dexamethasone (0.15 mg/kg IV q6h for 2 to 4 days) decreases mortality and morbidity for patients >1 month of age with acute bacterial meningitis with no increased risk of GI bleeding.
  - Corticosteroids are associated with lower rates of hearing loss and neurologic sequelae.
- Adults
  - Initiate in adults and continue only if CSF Gram stain shows gram-positive diplococcus or if blood or CSF positive for S. pneumoniae.
    - Nonsignificant reduction in mortality (RR 0.90, 95% CI 0.53–1.05); p value = .009
    - Lower rates of severe hearing loss (RR 0.67, 95% CI 0.51–0.88), any hearing loss (RR 0.74, 95% CI 0.63–0.87), and neurologic sequelae (RR 0.83, 95% CI 0.69–1.00)
    - Decreased mortality in S. pneumoniae (RR 0.8, 95% CI 0.20–0.59) but not in H. influenzae or N. meningitidis
  - Associated with increased recurrence of fever (RR 1.27, 95% CI 1.09–1.47)
  - Dexamethasone: 0.15 mg/kg IV q6h (start 15 to 20 minutes before or with antibiotic) for 2–4 days
    - Dexamethasone should only be continued if the CSF Gram stain and/or CSF or blood culture reveal S. pneumoniae.

**Second Line**
Antipseudomonal penicillins should be given in combination with other appropriate agents.
- Aztreonam 2 g IV q6–8h
- Fluoroquinolones (e.g., ciprofloxacin) IV 400 mg q8–12h
- Meropenem IV 2 g q8h

**ISSUES FOR REFERRAL**
Consultation from infectious disease and/or critical care specialist

**SURGERY/OTHER PROCEDURES**
Postsurgical bacterial meningitis, or associated with head trauma or shunt: Empiric cover for MRSA and aerobic gram-negative organisms, such as Pseudomona spp, and Enterobacteriaceae.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Bacterial meningitis requires hospitalization.
  - ICU monitoring may be needed.
  - Patients with suspected meningococcal infection require respiratory isolation for 24 hours.
- Consider home therapy to complete IV antibiotics once clinically stable and culture/sensitivity results are known.
- Droplet precautions of hospitalized patients as soon as diagnosis is suspected through the first 24 hours of antimicrobial therapy.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Brainstem auditory—evoked response hearing test for infants before hospital discharge
- Vaccinations
  - 4 doses Hib conjugate vaccine recommended during infancy
  - Meningococcal conjugate vaccine quadrivalent (MCV4) is given to children aged 11 to 12 years with a booster at 16 years.
  - Immunizing infants <3 months old with MCV4 does not reduce morbidity or mortality, and vaccinating pregnant women does not reduce infant infections.
  - Administer 2 doses MCV4 at least 2 months apart to adults with the following:
    - HIV, functional asplenia
    - Persistent complement deficiencies
  - Administer 1 dose of meningococcal vaccine to:
    - Military recruits
    - Microbiologists routinely exposed to isolates of N. meningitidis
    - Those who travel to or live in countries where meningitis is hyperendemic or epidemic
    - 1st-year college students up through age 21 years who live in residence halls if they have not received a dose on or after their 16th birthday
  - MCV4 is preferred for adults ≤55 years of age; meningococcal polysaccharide vaccine (MPSV4) is preferred for adults aged ≥56 years.
  - Revaccination with MCV4 every 5 years is recommended for adults previously vaccinated with MCV4 or MPSV4 who are at increased risk.
  - For patients with complement deficiencies, CDC recommends meningococcal conjugate vaccine and serogroup B meningococcal vaccine.
– Patients taking eculizumab are at increased risk for meningococcal disease.

**Prophylaxis (2)[A]**

– Only for close contacts of patients, effective up to 2 weeks after treatment without leading to resistance
– Rifampin is effective in eradicating N. meningitidis up to 4 weeks after treatment but may lead to resistance.
– Rifampin: 600 mg PO BID for 2 days
– Ciprofloxacin: 500 mg PO for 1 dose
– Ceftriaxone: 250 mg IM for 1 dose
– Chemoprophylaxis for close contacts of patients with confirmed meningococcal meningitis
  – Closer than 3 feet for >8 hours or those exposed to oral secretions and exposed during the 7 days prior to and 1 day after the start of antibiotics

**DIET**

Regular, as tolerated, except with syndrome of inappropriate secretion of antidiuretic hormone

**PROGNOSIS**

– Overall case fatality: 10–14%
– Bacterial meningitis is fatal in 5–40% of children and 20–50% of adults despite treatment.
– Mortality rate of untreated disease approaches 100%

**COMPLICATIONS**

– Seizures: 20–30% focal neurologic deficit
– Cranial nerve palsies (III, VI, VII, VIII) in 10–20% of cases; usually transient
– Sensorineural hearing loss: 10% in children
– Neurodevelopmental sequelae: 30% with subtle learning deficits
– Obstructive hydrocephalus, subdural effusion
– Inappropriate antidiuretic hormone secretion
– Elevated intracranial pressure: herniation, brain swelling
– Purpura fulminants
– Meningococcal-induced microvascular thrombosis and DIC
– Septic shock

**REFERENCES**

**CODES**

**ICD10**

– G00.9 Bacterial meningitis, unspecified
– G00.2 Streptococcal meningitis
– G00.8 Other bacterial meningitis
CLINICAL PEARLS

- Rapidly evolving petechial rash (purpura fulminans) is more common in meningococcal disease.
- Do not delay empiric therapy for lumbar puncture if meningitis is suspected and lumbar puncture not immediately available.
- Brudzinski and Kernig signs of meningeal irritation are unreliable for diagnosing (or ruling out) meningitis.
- Insufficient evidence to recommend dexamethasone for meningitis caused by other bacteria rather than Streptococcus pneumoniae.
- Presentation can be indolent at the extremes of age, immunocompromised patients, and in patients with partially treated infections.
BASICS

DESCRIPTION

- A clinical syndrome characterized by fever with signs/symptoms of acute meningeal inflammation resulting from a viral infection.
- Viral meningitis (VM) is the most common cause of aseptic meningitis (no identifiable bacterial pathogen in cerebrospinal fluid [CSF]).
- System(s) affected: Nervous

EPIDEMIOLOGY

Incidence

- Estimated 30,000 to 75,000 VM cases and 26,000 to 42,000 VM hospitalizations annually in United States.
- Most common form of infectious meningitis.
  - The annual incidence of VM is higher than all other causes of meningitis combined.
- Peaks June 1 to October 31.
  - Nonpolio enteroviruses and arthropod-borne viruses predominate in warm months (70% of cases July to October).
  - Mumps- and influenza-related meningitis usually occur in the winter and spring in epidemic form. This is less common due to routine vaccination.

ETIOLOGY AND PATHOPHYSIOLOGY

- In immunocompetent hosts, VM is generally caused by virus with neurotropic predilection.
- Less commonly, direct neural transmission occurs from an acute flare up of a chronic viral illness (such as herpes simplex virus [HSV]) already present in an immunocompetent host.
- 85–95% of VM cases are caused by enterovirus family, including coxsackievirus A and B, echovirus, and enterovirus A71. These are typically transmitted via the fecal–oral route.
- Less common: HSV-1, HSV-2, varicella-zoster virus (VZV), adenovirus, lymphocytic choriomeningitis virus (LCMV), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, parvovirus B19, mumps, Toscana virus.
- Parechovirus 3 is the most common cause of VM in infants <90 days old.
- Arthropod-borne viruses: Arboviruses such as West Nile virus, St. Louis encephalitis virus, California encephalitis virus.
- Recurrent benign lymphocytic (Mollaret) meningitis is generally associated with HSV-2 (80% of cases).

Genetics

None identified

RISK FACTORS

- Close contact with known cases of VM.
- Age (most common in children <1 years with second peak in children >5 years). VM is 20 times more common in children <1 than in older children, adolescents, and adults.
Immunocompromised host (patients more susceptible to CMV, HSV, and adenovirus)

**Geriatric Considerations**
Cases of VM in the elderly are rare (most common cause is VZV, HSV); consider alternative diagnoses (e.g., carcinomatous meningitis, medication-induced aseptic meningitis).

**GENERAL PREVENTION**
- Limit exposure to known hosts; practice hand washing and general hygiene procedures.
- Avoid sharing drinks/cups and silverware with others, especially those who are ill.
- Avoid exposure to mosquitos and ticks.

**COMMONLY ASSOCIATED CONDITIONS**
Encephalitis; neurologic deficits; myopericarditis; neonatal enteroviral sepsis

**DIAGNOSIS**

**HISTORY**
Predominant adult symptoms include acute onset (hours to days) of:
- Fever (76–100% of patients)
- Headache (prominent early symptom)
- Photophobia
- Myalgias
- Nausea, vomiting
- Malaise
  - In infants, nonspecific symptoms are more common including poor feeding, fever, and irritability.
- Nuchal rigidity (>50%)
  - Note: If altered mental status (AMS), consider encephalitis. Encephalitis is associated with neurologic dysfunction, such as behavioral change, focal neurologic deficits, etc. There is a continuum between meningitis and encephalitis: “meningoencephalitis.” Encephalitis is associated with increased morbidity and mortality.
- Additional historical elements:
  - Travel and exposure history
  - Sexual activity (e.g., HSV, HIV)
  - Outdoor activities (Lyme disease)
  - Exposure to rodent feces and/or urine (LCMV—lymphocytic choriomeningitis mammarenavirus)
  - Solid-organ transplant (LCMV, CMV)
  - Immunocompromised host (CMV, HSV, adenovirus)
  - History of VZV infection
  - Immunization status (mumps virus, influenza virus, varicella-zoster virus)

**PHYSICAL EXAM**
- Altered mental status (consider encephalitis)
- Fever (>100.4°F/38°C); tachycardia; tachypnea; hypotension
- Thorough neurologic exam to look for focal deficits in cognition, motor function, sensory function, cerebellar function
Meningeal signs (should not be used exclusively to rule meningitis in or out):
- Nuchal rigidity: new neck stiffness
- Brudzinski sign: neck flexion elicits involuntary hip and knee flexion in supine patient
- Kernig sign: resistance to knee extension following flexion of hips to 90 degrees by physician
- Jolt accentuation test: rapid horizontal rotation of the head accentuates the headache

Genital lesions (85% of HSV-2 cases have active lesions; can precede meningeal symptoms by up to a week)
- Parotitis (mumps)
- Asymmetric flaccid paralysis (West Nile virus)
- Infants: bulging fontanelle and/or septic appearance possible

Mucocutaneous findings
- Vesicular rash in hand, foot, and mouth disease (coxsackievirus)
- Herpangina (coxsackievirus A)
- Herpes zoster rash or recent VZV vaccination
- Erythema migrans or cranial neuropathy (Lyme disease [Borrelia burgdorferi])
- Generalized maculopapular rash (echovirus 9, syphilis, HIV, Rocky Mountain spotted fever)
- Oropharyngeal thrush (HIV)
- Petechial rash (Neisseria meningitidis)

DIFFERENTIAL DIAGNOSIS
- Bacterial meningitis (BM)
- Fungal meningitis (consider if immunocompromised)
- Encephalitis
- Other infectious agents:
  - Tuberculosis; syphilis; leptospirosis; Lyme disease; Rocky Mountain spotted fever; ehrlichiosis; Coccidioides; Cryptococcus neoformans; amebiasis; Rickettsial infection
- Parameningeal infections (e.g., subdural empyema)
- Postinfectious encephalomyelitis
- Viral syndrome (e.g., influenza)
- Leukemia, lymphoma, or carcinomatous meningitis
- Migraine/tension headache
- Acute metabolic encephalopathy
- Chemical meningitis
- Postoperative aseptic meningitis
- Drug-induced meningitis (nonsteroidal anti-inflammatory drugs, intravenous immunoglobulin, trimethoprim/sulfamethoxazole, amoxicillin, cetuximab, natalizumab, infliximab, lamotrigine)
- Brain/epidural abscess
- Inflammatory disorders (e.g., Behçet, sarcoidosis, systemic lupus erythematosus)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Rule out BM:
  - Whether patients with low suspicion of BM need a lumbar puncture (LP) is debatable. Currently, LP remains the standard of care for suspected VM or BM. In children, early LP is associated with decreased antibiotic use and reduced hospital days.
- Bacterial Meningitis Score (BMS): a validated clinical decision rule to identify children (≥29 days of age) at very low risk of BM. Sensitivity 99%, specificity 62%. Not all institutions support use of clinical decision tools to rule in/out BM.
  - CSF Gram stain positive (2 points)
  - CSF protein >80 mg/dL (1 point)
  - Blood absolute neutrophil count ≥10,000/mm$^3$ (1 point)
  - Seizures with illness (1 point)
  - CSF neutrophils >1,000/mm$^3$ (1 point)
    - 0 points: VM likely
    - 1 point: VM less likely
    - 2 to 6 points: BM more likely
- CSF bacterial culture is positive in 80–90% of BM patients who did not receive antibiotics for 2 to 4 hours prior to LP.
- Risk factors for cerebral herniation with LP: signs of increased intracranial pressure (e.g., focal neurologic findings, papilledema, AMS, vomiting), known ventricular obstruction, new-onset seizure, immunocompromised state, hypertension with bradycardia, trauma. Consider head CT before LP.
- Contraindications for LP: local infection over potential LP site, suspected epidural abscess, use of anticoagulation or coagulopathy, and possibility of cardiorespiratory compromise due to patient positioning during procedure
- Post-LP headache: occurs in 37% of patients within 48 hours. Consider the use of an atraumatic LP needle or larger gauge (smaller diameter) LP needle to decrease the risk of post-LP headache.
- CSF analysis: glucose, protein, white blood cell count with differential, red blood cell (RBC) count, Gram stain, culture; consider CSF lactate.
  - CSF lactate helps differentiate BM from VM (decreased sensitivity if pretreated with antibiotics) (1,2)[A].

- Typical CSF findings in VM
  - Elevated WBC count: 10 to 500/mm$^3$ (can be up to 1,000), classically lymphocyte predominance (>50% lymphocytes, though this pattern is less consistent in younger patients). Note: More cases without lymphocytic pleocytosis noted in enterovirus VM; instead, may show neutrophilic predominance in first 48 hours, especially in pediatric population.
  - Decreased or normal glucose (relative to serum)
  - Protein normal to slightly elevated (<150 mg/dL)
  - Negative Gram stain and bacterial culture
  - Elevated opening pressure
  - RBCs in CSF (Consider HSV meningitis/encephalitis.)
  - Pathogen identification:
    - Current practice: Nucleic Acid Amplification Tests (NAATs) such as polymerase chain reaction (PCR), with sensitivity of 95–100% for HSV-1 and 2, EBV, enterovirus. Sensitivity for enterovirus may decrease if CSF collected >48 hours after onset of symptoms.
    - RT PCR test is approved for enteroviral meningitis; results in 2 to 3 hours
    - Serology can be performed for many arthropod-borne viruses.
- Other labs: CBC, blood culture, blood glucose; consider serum C-reactive protein (CRP) and
procalcitonin (PCT).

- CBC: normal or mildly elevated WBC
- Serum PCT elevation has been correlated with BM. PCT levels of >0.25 to 0.28 are 96% sensitive and 99% specific for BM. Elevated serum CRP was 82% sensitive and 81% specific (1)[B],(3)[A].
- PCT has also been validated in children (sensitivity 87.5–100%, specificity 66–100%); however, cutoff ranges vary from 0.2 to 3.3 ng/mL between studies and are assay dependent (4)[A]. There may be a role for CSF PCT to help differentiate BM from VM.

- Electroencephalogram if concern for encephalitis
- Fungal, mycobacterial cultures, VDRL if clinically indicated
- Indication for imaging depends on clinical scenario. Consider CT versus MRI if abnormal hospital course of VM (e.g., prolonged course or increased symptoms).
- Historic gold standard: CSF viral culture for enteroviruses, HSV, and mumps. This has low sensitivity (<6–20%); viral culture may yield no additional information over nucleic acid amplification.

**Follow-Up Tests & Special Considerations**

Disorders that may alter lab results:
- Diabetes: Consider current blood sugar level to correlate with CSF glucose level.
- Preexisting neurologic diseases (e.g., history of stroke or transient ischemic attack, intracranial neoplasm, demyelinating disease)

---

**TREATMENT**

**GENERAL MEASURES**

Management includes supportive care (e.g., pain control, IV fluids) and low threshold for empiric antibiotics for BM pending laboratory results.

**MEDICATION**

**First Line**
- Analgesics (adult doses; titrate doses to pain relief)
  - Morphine 2.5 to 5.0 mg IV q3–4h
  - Hydromorphone (Dilaudid) 0.2 to 2.0 mg IV q2–3h
  - Hydrocodone (Norco) 5/325 mg 1 to 2 tablets PO q6h OR oxycodone (Percocet) 5/325 mg 1 to 2 tablets PO q4–6h
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg IV q8h
  - Metoclopramide (Reglan) 10 to 20 mg IV/IM q4–6h
- Antipyretics: acetaminophen (Tylenol) 650 mg PO or rectal suppository q4h
- Antiviral agents (adult dose): Initiate empiric acyclovir at 10 mg/kg IV q8h for patients with CSF pleocytosis, negative Gram stain, and suspicion for HSV while awaiting results of definitive (e.g., HSV PCR) testing.
- Antibiotics (targeted to most likely pathogen)
  - Not indicated for treatment of VM; however, low threshold for empiric treatment if BM is suspected. Consider especially in elderly, those pretreated with antibiotics, and immunocompromised patients. In pediatrics, treat with antibiotics in suspected VM if ill-
appearing, <3 months old, or immunocompromised.
  – If unclear etiology but very low risk for BM, treat symptomatically and observe in the inpatient setting pending laboratory results.

- IVIG
  – Research currently underway investigating possible benefit though not yet FDA approved (5).
- Corticosteroids
  – Not indicated for treatment in VM
  – Consider if concerned for BM.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Generally VM is treated as outpatient once BM is excluded. Hospitalize for VM with complications (e.g., encephalitis), empiric antibiotic therapy, pain/fluid control, immunocompromised patient, or <1 year old.
  – Most children with VM are hospitalized (91%).
- IV fluids: crystalloid bolus or continuous infusion, based on hydration status and clinical presentation
- Neurologic monitoring for changes in mental status, fever, neck stiffness, hyaluronic acid, etc., to assess disease progression
- Contact precautions; private room until BM ruled out
- Encourage hand washing.
- Discharge depends on likelihood of BM, WBC count, and clinical parameters (dehydration, functional level, social circumstances, and ability to follow up).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Primary care follow-up to ensure resolution

Patient Monitoring
- Monitor for relapse or exacerbation of symptoms.
- Monitor for neurologic/neuroendocrine complications:
  – Seizures, cerebral edema, syndrome of inappropriate antidiuretic hormone (SIADH)
  – Assess ability to have companion monitor change in mental/neurologic status if patient discharged.

DIET
Consider NPO if nausea or vomiting. Advance diet as tolerated.

PATIENT EDUCATION
- Discuss low probability of transmission to contacts.
- Expected duration of illness is 5 to 10 days.
- Recurrence of headache, myalgia, and weakness is possible over 2 to 3 weeks.

PROGNOSIS
- Complete recovery generally within 7 to 10 days
- Headaches and other neurologic symptoms may intermittently persist for weeks to months.
- Only 0.6% of hospitalizations for VM result in death.
- In neonatal population, enteroviral meningitis has been associated with normal growth and development at 1 year in most patients.

**COMPLICATIONS**
- Common: fatigue, irritability, muscle weakness
- Rare: seizures, abscess, mastoiditis
- Potential residual postmeningeal cognitive impairment.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
- Meningitis, Bacterial
- Algorithm: Delirium

**CODES**

**ICD10**
- A87.9 Viral meningitis, unspecified
- A87.1 Adenoviral meningitis
- A87.0 Enteroviral meningitis
CLINICAL PEARLS

- VM cannot be reliably distinguished from BM based on clinical findings alone.
- Hospitalize potential cases of BM for evaluation and treatment with broad-spectrum antibiotics until BM has been ruled out.
- VM is more common than BM, especially if vaccination rates are high.
- Antibiotic administration in the hours prior to LP and CSF analysis may result in “partially treated” BM lab results, mimicking VM.
- Morbidity with VM is low but increases if there is associated encephalitis.
MENINGOCOCCAL DISEASE
Han Q. Bui, MD

BASICS

DESCRIPTION

- Meningococcemia is a blood-borne infection caused by Neisseria meningitidis.
- Bacteremia without meningitis: Patient is acutely ill and may have skin manifestations (rashes, petechiae, and ecchymosis) and hypotension.
- Bacteremia with meningitis: sudden onset of fever, nausea, vomiting, headache, decreased ability to concentrate, and myalgias
- Disease progresses rapidly (within hours).
- Skin findings and hypotension may be present.
  - A petechial rash appears as discrete lesions 1 to 2 mm in diameter; most frequently on the trunk and lower portions of the body; seen in >50% of patients on presentation
  - Purpura fulminans is a severe complication of meningococcal disease and occurs in up to 25% of cases. It is characterized by acute onset of cutaneous hemorrhage and necrosis due to vascular thrombosis and disseminated intravascular coagulopathy.

EPIDEMIOLOGY

Incidence

- The mortality rate is ~13%.
  - 11–19% of survivors suffer serious sequelae, including deafness, neurologic deficits, or limb loss due to peripheral ischemia.
- Disease is seasonal, peaks in December/January.
- In 2017, there were ~350 cases of reported meningococcal disease (incidence rate of 0.18 cases per 100,000 persons) (1).
  - Most common in adolescents and young adults, followed by infants <1 year

ETIOLOGY AND PATHOPHYSIOLOGY

- N. meningitidis is a gram-negative diplococcus with at least 13 serotypes.
- N. meningitidis has an outer coat that produces disease-causing endotoxin.
  - Serogroup B is the predominant cause of meningococcal meningitis in children <1 year.
  - Serogroup C is the most common cause of meningococcal disease in the United States.
  - Serogroup Y is the predominant cause of meningococccemia in the elderly (2).
- Major serogroups worldwide are A, B, C, Y, and W-135.
  - W-135 is the major cause of disease in the “meningitis belt” of sub-Saharan Africa.

Genetics

Late complement component deficiency has an autosomal recessive inheritance.

RISK FACTORS

- Age: 3 months to 1 year
- Late complement component deficiency (C5, C6, C7, C8, or C9)
- Asplenia (1)
Living in close quarters (e.g., household contacts, nursery/daycare, dormitories, military barracks)

Exposure to active (and/or) passive tobacco smoke

GENERAL PREVENTION

Two vaccines are currently licensed for use in the United States. Each contains antigens to serogroups A, C, Y, and W-135. Neither provides immunity against serotype B, which is responsible for 1/3 of U.S. cases.

- Meningococcal polysaccharide vaccine (MPSV-4): recommended for patients ≥55 years at elevated risk
  - Short duration of protection: 1 to 3 years for patients age <5 years; 3 to 5 years for adolescents and adults
  - Often used for patients requiring short duration of protection—traveling to endemic areas, college freshmen, community outbreaks
- Meningococcal conjugate vaccine (MCV-4): recommended for patients 2 to 55 years of age

The FDA has licensed two serogroup B meningococcal (MenB) vaccines. The first (MenB-FHbp) is a 3-dose series. The second (MenB-4C) is a 2-dose series. Both vaccines were approved for use in persons aged 10 to 25 years. Individuals aged ≥10 years who are at increased risk for meningococcal disease due to persistent complement component deficiencies, anatomic or functional asplenia, should receive MenB vaccine.

Protective levels of antibody are achieved ~7 to 10 days after primary immunization.

Vaccine is recommended for everyone aged 11 to 18 years and individuals 19 to 55 years who are at increased risk for meningococcal disease.

Guillain-Barré syndrome has been associated with the MCV-4 vaccine; therefore, a personal history of Guillain-Barré is a relative contraindication for this vaccine.

Centers for Disease Control and Prevention international travel advisory

- Vaccine is required by the government of Saudi Arabia for Hajj pilgrims >2 years of age.
- The vaccine should be given to travelers to sub-Saharan Africa (“meningitis belt”).

DIAGNOSIS

HISTORY

Symptoms
- Sudden onset of fever, nausea, vomiting, headache, myalgias, chills, rigor, and/or sore throat (nonsuppurative)
  - Pharyngitis may be mistaken for streptococcal disease (strep throat).
  - Myalgia may be mistaken for severe “flu,” which also has a peak incidence in winter.
- Changes in mental status, decreased ability to concentrate, stiff neck, convulsions
- Assess possible exposures.

PHYSICAL EXAM

- Fever, hypotension, tachycardia
- Neurologic: nuchal rigidity, focal neurologic findings, coma, seizure
  - Focal neurologic findings and seizures are more commonly seen with Haemophilus influenzae or Streptococcus pneumoniae.
● Cardiopulmonary: signs of heart failure with pulmonary edema—gallop, rales
● Dermatologic: maculopapular rash, petechiae, ecchymosis, purpura
● Onset of specific meningitis symptoms (e.g., neck stiffness, photophobia, bulging fontanelle) can occur within 12 to 15 hours (4).
● Late signs of meningitis (e.g., unconsciousness, delirium, or seizures) occur after ~15 hours in infants <1 year and after ~24 hours in older children.

DIFFERENTIAL DIAGNOSIS
● Sepsis; bacterial meningitis (other organisms)
● Gonococcemia
● Acute bacterial endocarditis
● Rocky Mountain spotted fever
● Hemolytic uremic syndrome
● Gonococcal arthritis dermatitis syndrome
● Influenza

DIAGNOSTIC TESTS & INTERPRETATION

ALERT
● Isolation of N. meningitidis from a sterile site (blood or cerebrospinal fluid [CSF]) is the gold standard for diagnosing systemic meningococcal infection.
● Antibiotic administration may render blood and/or CSF culture negative within 2 hours.

Initial Tests (lab, imaging)
● Complete blood count with differential
  – Leukocytosis (left shift; toxic granulation) or leukopenia, thrombocytopenia
● Lactic acidosis
● Procalcitonin; often elevated in bacterial meningitis (5)
● Coagulation studies
  – Prolonged prothrombin time/partial thromboplastin time
  – Low fibrinogen
  – Elevated fibrin degradation products
● Blood culture
  – Blood culture positive for N. meningitidis
  – Cultures positive in 50–60% of cases
● CSF
  – Grossly cloudy
  – Increased white blood cells with polymorphonuclear predominance
  – Gram stain showing gram-negative diplococci
  – Glucose-to-blood glucose ratio <0.4
  – Protein >45 mg/dL
  – Positive for N. meningitidis antigen (medication-assisted treatment or polymerase chain reaction)
    – CSF culture positive in 80–90% of cases
● Head CT prior to lumbar puncture (LP) if concern for space-occupying lesions or if focal findings on neurologic examination

Test Interpretation
Disseminated intravascular coagulation (DIC)
Meningeal exudates
Polymorphonuclear infiltration of meninges
Hemorrhage of adrenal glands

**TREATMENT**

**MEDICATION**

**First Line**

**Antibiotics (5)[A]**
- Begin treatment as soon as meningococcal meningitis is suspected.
- Age guides empiric treatment.
  - Preterm to <1 month: ampicillin plus cefotaxime or ampicillin plus gentamicin
    - Cefotaxime
      - 0 to 7 days: 50 mg/kg q12h
      - 8 to 28 days: 50 mg/kg q8h
    - Ampicillin
      - >2,000 g
        - 0 to 7 days: 50 mg/kg q8h
        - 8 to 28 days: 50 mg/kg q6h
      - <2,000 g
        - 0 to 7 days: 50 mg/kg q12h
        - 8 to 28 days: 50 mg/kg q8h
  - 1 month to 50 years: cefotaxime or ceftriaxone plus vancomycin
    - If severe penicillin allergy: chloramphenicol plus trimethoprim-sulfamethoxazole (TMP-SMX) plus vancomycin
  - >50 years of age or patients with significant comorbidity, alcohol abuse, or impaired immunity: ampicillin plus ceftriaxone plus vancomycin
    - Ampicillin: 2 g IV q4h
    - Ceftriaxone: 2 g IV q12h
    - Vancomycin: 30 to 45 mg/kg/day IV divided q6h
    - If severe penicillin allergy: TMP-SMX plus vancomycin
  - Penicillin G
    - Effective if the isolate is penicillin sensitive
    - Penicillin can be used if the isolate has a penicillin minimum inhibitory concentration (MIC) of <0.1 μg/mL.
    - For isolates with a penicillin MIC of 0.1 to 1.0 μg/mL, a 3rd-generation cephalosporin is preferred.
    - Penicillin G: 4 million units IV q4h (pediatric dose: 0.25 mU/kg/day IV divided q4–6h)
      OR ampicillin: 2 g IV q4h (pediatric dose: 200 to 300 mg/kg/day IV divided q6h)
    - Duration of treatment: 7 days (4)

**Dexamethasone**
- Indications
  - Known or suspected pneumococcal meningitis in selected adults
  - Children with H. influenzae type B meningitis
- Dexamethasone is often given initially in adults and children with suspected bacterial meningitis while awaiting microbiologic study results.
- Dexamethasone has not been shown to be of benefit in meningococcal meningitis and should be discontinued once the diagnosis is established.
- Dosage
  - Infants and children >6 weeks: IV 0.15 mg/kg/dose q6h for the first 2 to 4 days of antibiotic treatment
  - Start 10 to 20 minutes before or with the first dose of antibiotic.

- Chemoprophylaxis
  - Indications
    - Close contacts: those with prolonged (>8 hours) close contact (<3 feet) to the patient or those directly exposed to the patient’s oral secretions between 1 week before the onset of the patient’s symptoms and until 24 hours after initiation of appropriate antibiotic therapy (2)
      - Examples: household members; close contacts in nursery, daycare centers, nursing homes, dormitories, military barracks, correctional facilities, and other closed institutional settings
    - No chemoprophylaxis is indicated for casual contacts, including most health care workers, unless exposed to respiratory secretions.
  - Timing
    - Ideally <24 hours after case identification
    - Chemoprophylaxis should not be administered if >14 days since exposure.
  - Prophylactic regimens
    - Rifampin, ciprofloxacin, and ceftriaxone
      - Ceftriaxone
        - Recommended for pregnant women
        - Adults: 250 mg IM as a single dose
      - Rifampin (meningococcal prophylaxis)
        - Adult: 600 mg IV or PO q12h for 2 days
        - Pediatric
          - <1 month: 10 mg/kg/day in divided doses q12h for 2 days
          - Infants and children: 20 mg/kg/day in divided doses q12h for 2 days (max 600 mg/dose)
      - Ciprofloxacin
        - Adults: 500 mg PO as a single dose
  - Vaccination
    - For household contacts (if the case is from a vaccine-preventable serogroup)
  - Precautions
    - Adjust the dosage of medications in patients with severe renal dysfunction.

- Second Line
  - For meningitis
    - Chloramphenicol: 1 g IV q6h (pediatric dose: 75 to 100 mg/kg/day divided q6h) or ceftriaxone 2 g IV q12h (pediatric dose: 80 to 100 mg/kg/day divided q12–24h)
    - In large outbreaks, a single dose of long-acting chloramphenicol has been used. Single-dose ceftriaxone shows equal efficacy in one randomized controlled trial.
  - Precautions
- Ceftriaxone should not be used in patients with a history of anaphylactic reactions to penicillin (e.g., hypotension, laryngeal edema, wheezing, hives).
- Chloramphenicol may cause aplastic anemia.

ISSUES FOR REFERRAL
Potential complications
- Seizure activity
- DIC
- Acute respiratory distress syndrome
- Renal failure
- Adrenal failure
- Multisystem organ failure

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Begin antibiotics (± corticosteroids) and obtain LP immediately if meningitis is suspected.
- Droplet isolation for 24 hours after starting antibiotics
- IV fluids: Replace volume as needed; with septic shock, large volumes of crystalloid may be required.

ONGOING CARE

PATIENT EDUCATION
Educate family and close contacts regarding the risk of contracting meningococcal infection.

PROGNOSIS
Overall mortality is 13%.

COMPLICATIONS
- DIC
- Acute tubular necrosis
- Neurologic: sensorineural hearing loss, cranial nerve palsy, seizures
- Obstructive hydrocephalus
- Subdural effusions
- Acute adrenal hemorrhage
- Waterhouse-Friderichsen syndrome

REFERENCES

ADDITIONAL READING

CODES

ICD10
- A39.4 Meningococcemia, unspecified
- A39.0 Meningococcal meningitis
- A39.2 Acute meningococcemia

CLINICAL PEARLS

- Invasive meningococcal disease can be rapidly fatal. Rapid identification and early treatment with antibiotics is essential to promote good clinical outcomes. Treat then test in suspected cases.
- Provide chemoprophylaxis to close contacts.
- Vaccinate at-risk populations to prevent disease.
MENISCAL INJURY
Jennifer B. Schwartz, MD

BASICS

DESCRIPTION
- The menisci are fibrocartilaginous structures between the femoral condyles and tibial plateaus.
- The menisci help stabilize the knee and distribute forces across the joint.
- There are acute/traumatic and chronic/degenerative meniscal tears.

Pediatric Considerations
- Meniscal injuries are rare in children <10 years of age and are often due to a discoid meniscus.
- MRI is less sensitive and specific for diagnosing meniscal tears in children <12 years of age.
- Meniscal repair is an effective treatment option with good clinical outcomes in the pediatric/adolescent population (1,2).

EPIDEMIOLOGY
Bimodal age distribution—young athletes (traumatic) and older patients >40 years (degenerative)

Incidence
Medial meniscus more commonly injured

Prevalence
One of the most common musculoskeletal injuries

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute/traumatic tears occur due to a twisting motion of the knee with foot planted.
- Chronic/degenerative tears occur with minimal trauma or overuse.

Genetics
Presence of a discoid meniscus increases the risk for a meniscal tear. No specific gene locus has been identified.

RISK FACTORS
- Acute/traumatic tear:
  - High degree of physical activity (especially cutting sports)
  - Younger patients
  - Anterior cruciate ligament (ACL) insufficiency
- Chronic/degenerative tear:
  - Increased age (>60 years)
  - Obesity
  - Work-related kneeling/squatting/ Climbing stairs

GENERAL PREVENTION
- Treatment and rehabilitation of previous knee injuries, particularly ACL injuries
- Strengthening and increased flexibility of quadriceps and hamstring muscles

COMMONLY ASSOCIATED CONDITIONS
• Acute/traumatic tear
  – ACL is concomitantly torn in 1/3 of cases.
• Degenerative tear:
  – Baker cyst—association with medial meniscal tears
  – Osteoarthritis (OA)

 DIAGNOSIS

HISTORY
• Knee pain (increased with knee flexion)
• Pain with descending stairs
• Noncontact twisting mechanism
• ± Locking, catching
  – Limited association between self-reported mechanical symptoms and presence of meniscal
tear on arthroscopy

PHYSICAL EXAM
• Effusion—typically >24 hours’ postinjury
• Joint line tenderness
• Decreased range of motion
• Pain with full flexion (posterior horn tear) or extension (anterior horn tear)
• Accuracy of special tests (McMurray, Apley grind test) varies—special tests not sensitive nor
  specific.

DIFFERENTIAL DIAGNOSIS
• ACL or collateral ligament tear
• Pathologic plica
• Osteochondritis dissecans
• Loose body or fracture
• OA
• Patellofemoral syndrome

DIAGNOSTIC TESTS & INTERPRETATION
• Plain radiographs can detect fractures, loose bodies, or arthritic changes.
• Ultrasound may help identify meniscal tears.
• MRI is the most accurate and primary imaging study for meniscal tears.

Follow-Up Tests & Special Considerations
Meniscal tears are often found incidentally on MRI and may not be the cause of patient’s
symptoms
• Incidental tears found on MRI in 60% asymptomatic patients (3)[C]
• Asymptomatic tears more common in older patients, those with OA

Diagnostic Procedures/Other
Arthroscopy may be needed if the MRI is indeterminate.
TREATMENT

GENERAL MEASURES
- Nonsurgical management is appropriate first-line treatment for symptomatic meniscal tears without mechanical symptoms (3)[C].
- Conservative treatments include: rest, ice, activity modification, over-the-counter medications, physical therapy, intra-articular corticosteroid injections.
- Consider surgical intervention if:
  - Concurrent injuries (i.e., ACL tear)
  - No symptom improvement after 3 to 6 months of conservative treatment
  - Young patients (<30 years) or active patients with an acute tear
  - Mechanical symptoms (knee “catching” or “locking”)
- For degenerative tears:
  - Recommend physical therapy/supportive care first—no increased benefit from surgery versus PT with degenerative meniscal tears age >40 years (4)[B]
  - In middle age patients with degenerative tears and no OA, surgery should be considered only when no response to conservative management after 3 months (5)[C]
- For traumatic tears:
  - Consider surgery—These patients generally have more improvement after surgery compared with patients with degenerative tears (6)[C].
  - No evidence for best treatment (surgical versus nonsurgical) in patients <40 years of age.

MEDICATION
First Line
- NSAIDs, opioid analgesics if severe pain
- Corticosteroid injection (5 mL Lido- caine plus 1 mL Depo-Medrol (80 mg/mL) or equivalent)

ISSUES FOR REFERRAL
Surgical consult for patients meeting operative criteria or wishing surgical repair

ADDITIONAL THERAPIES
- Rehabilitation is required for both surgical and nonsurgical patients.
- Weight control: Weight gain is associated with increased cartilage loss and pain.
- Platelet-rich plasma (PRP) may or may not improve symptoms of meniscal tears.

SURGERY/OTHER PROCEDURES
- Meniscectomy removes the injured portion of the meniscus.
  - Both partial and total meniscectomy can lead to articular cartilage degeneration and OA.
  - Higher risk if >40 years of age, high body mass index, valgus malalignment
- Meniscal repair or replacement is preferred over meniscectomy when possible and may have better outcomes.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Return to play requires that the patient be pain free, have full range of motion, and full
Following meniscal repair, patients can generally return to activities in 3 to 6 months.

**PATIENT EDUCATION**

Patients should be aware of the risks and benefits of surgery compared with conservative treatment.

**PROGNOSIS**

Prognosis better if surgery is done within 8 weeks (acute tear), patient is <30 years of age, or tear is peripheral/lateral and <2.5 cm.

**COMPLICATIONS**

- Meniscectomies may eventually lead to OA.
- Risk of developing OA increases 6-fold 20 years after a meniscectomy.

**REFERENCES**

**ADDITIONAL READING**

Algorithm: Knee Pain

CODES
ICD10

S83.209A Unsp tear of unsp meniscus, current injury, unsp knee, init
S83.249A Oth tear of medial meniscus, current injury, unsp knee, init
S83.289A Oth tear of lat mensc, current injury, unsp knee, init

CLINICAL PEARLS

Chronic/degenerative meniscal tears are common in patients >40 years old and are generally managed conservatively.

Acute/traumatic meniscal tears are more common in young athletes and may require surgery.

MRI is imaging modality of choice to identify meniscal tears.

In patients opting for surgery, meniscal repairs have a better functional outcome and decreased risk of OA compared with meniscectomy.
MENOPAUSE
Jill Patton, DO

BASICS

DESCRIPTION
- Natural menopause: 12 consecutive months of amenorrhea in a nonpregnant woman ≥40 years of age; mean age of 51 years
  - Results from loss of ovarian activity
  - Not associated with a pathologic etiology
- Perimenopause/menopausal transition (MT): the period from the onset of irregular menses to the final menstrual cycle. Begins on average 4 years before menopause; starts at mean age of 47 years
- Postmenopause: usually >1/3 of a woman’s life
- Primary ovarian insufficiency: irregular or cessation of ovulatory menstrual cycles before age 40 years
- Surgical menopause: removal of functioning ovaries leading to immediate menopause

EPIDEMIOLOGY
- The median age of menopause is 51 years.
- 5% of women undergo menopause after age 55 years; another 5% between ages 40 and 45 years
- Occurs earlier in Hispanic women and later in Japanese American women as compared with Caucasians

Incidence
In the United States, 1.3 million women reach menopause annually.

ETIOLOGY AND PATHOPHYSIOLOGY
- As women age, the number of ovarian follicles decreases: Ovarian production of estrogen varies and then decreases. Follicle-stimulating hormone (FSH) production varies and then increases.
- Inadequate estradiol production leads to the absence of the luteinizing hormone (LH) surge causing failure to ovulate. Anovulation causes lack of progesterone production.
- Failure to produce estradiol leads to thinning of endometrial lining and eventually menstruation ceases.
- Estrone (produced by adipose tissue) becomes the dominant form of estrogen during menopause.

RISK FACTORS
- Aging
- Oophorectomy/hysterectomy
- Sex chromosome abnormalities (e.g., Turner syndrome and fragile X syndrome)
- Family history of early menopause
- Smoking (earlier age of onset by 2 years)
- Chemotherapy and/or pelvic radiation
GENERAL PREVENTION
Menopause is a physiologic event and associated with increased risk of long-term medical issues, including cardiovascular disease (CVD) and osteoporotic fractures.

- Decrease risk of CVD by:
  - Increasing exercise
  - Maintaining healthy diet and losing weight
  - Avoiding tobacco use
  - Treating hypertension, hyperlipidemia, and diabetes mellitus

- Decrease risk of osteoporotic fractures with:
  - Weight-bearing exercise and fall prevention
  - Avoidance of smoking and excessive alcohol intake
  - Dietary calcium of 1,200 mg/day
  - Adequate vitamin D intake (800 to 1,200 IU daily)
  - Fall prevention

DIAGNOSIS

HISTORY

- Cessation of menses:
  - Generally preceded by a period of irregular cycles with heavy vaginal bleeding followed by diminished vaginal bleeding

- Vasomotor symptoms reported by 80%:
  - Sudden unpleasant feeling of heat and sweating, most commonly over face, neck, and chest, typically lasting 1 to 5 minutes; intervals unpredictable
  - Generally begin 2 years before the final menstrual period, peak during 1 year after the final menstrual period, and then diminish
  - Frequency and duration varies: 87% of women who report flushes experience them daily; ~33% have >10 per day. Mean duration of symptoms lasts 4 to 10.2 years and may begin during MT and extend well past menopause.
  - Varies with ethnicity: greatest in African and Hispanic women and least in Asian women
  - More common in obese women

- Urogenital atrophy in 50%:
  - Vaginal/vulvar dryness, itching, dyspareunia, and possible sexual dysfunction
  - Alkaline vaginal pH and atrophy increases risk of vaginal infections and urinary tract infections.
  - Persists or worsens with aging

- Urologic symptoms (urgency, frequency, dysuria, incontinence) not clearly correlated with MT

- Anxiety/depression: Some studies show a new diagnosis of depression is 2.5 times more likely to occur during the MT as compared to premenopause.

- Sleep disturbance: Arousal from sleep and chronic insomnia linked with menopause.

- Change in intensity and severity of migraines

- Skin thinning, mild hirsutism, brittle nails

Geriatric Considerations
Vaginal bleeding in postmenopausal women is abnormal; thus, endometrial cancer/endometrioid adenocarcinoma (EAC) must be ruled out.
PHYSICAL EXAM

- Decrease in breast size and change in breast texture
- Genitourinary exam:
  - Atrophic vulva and vaginal mucosa
  - Increased risk for uterine prolapse

DIFFERENTIAL DIAGNOSIS

Pregnancy, thyroid diseases, pituitary adenoma, Sheehan syndrome, hypothalamic dysfunction, anorexia nervosa, Asherman syndrome, and obstruction of uterine outflow tract

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Lab testing for menopause is not required; the patient’s age and symptoms establish the diagnosis.
- If laboratory confirmation is desired:
  - Elevated serum FSH level >30 mIU/mL indicates ovarian failure.
  - Symptoms may precede lab changes.
- Infertility evaluation: may use elevated day 3 FSH, decreased antimüllerian hormone levels, and decreased antral follicle count to predict decreased ovarian reserve
- Estrogens, androgens, and oral contraceptive pills (OCPs) may alter lab results.

Follow-Up Tests & Special Considerations

- Pregnancy test
- TSH and prolactin level if pituitary disease is suspected
- Abnormal uterine bleeding, including postmenopausal bleeding, should be evaluated by transvaginal ultrasound (TVUS) and/or EMB. If endometrial stripe is <5 mm on TVUS, EAC is unlikely.
- U.S. Preventive Services Task Force (USPSTF) recommends mammogram every 2 years from ages 50 to 74 years.
- USPSTF recommends bone mineral density (BMD) screening with dual energy x-ray absorptiometry (DEXA) scan in postmenopausal women >65 years or <65 years if the risk for fracture is equivalent to that of a 65-year-old woman (using the FRAX tool to assess, https://www.sheffield.ac.uk/FRAX/). Risk factors include a previous history of fractures, low body weight, cigarette smoking, and family history of osteoporotic fracture.

Test Interpretation

- Abnormal BMD and DEXA scan results:
  - T-score on DEXA of −1 to −2.5 = osteopenia
  - T-score < −2.5 = osteoporosis
  - Defer to femoral neck T-score over spine T-score.
- Z-score measures age-matched mean bone density (not clinically useful).

TREATMENT

MEDICATION

First Line
Hormone therapy (HT): Developing an individual risk–benefit profile is essential. Treatment goal is to minimize menopausal symptoms to improve quality of life (1).

- The primary indication for HT is the treatment of moderate to severe vasomotor symptoms.
  - Oral estrogen or estrogen–progestin mix can reduce weekly hot flush frequency ~75% (2).
- HT also helpful with sleep disorders, urogenital atrophy, and lowers risk of osteoporotic fractures; may help with mood symptoms (3).
- In women with an intact uterus, give estrogen with progestin because unopposed estrogen carries an increased risk of EAC.

- Treatment regimens include but are not limited to:
  - Standard dose: conjugated equine estrogen (CEE) 0.625 mg/day or micronized estradiol 17β 1.0 mg/day or transdermal estradiol 17β 0.0375 to 0.050 mg/day
  - Low dose: CEE 0.30 to 0.45 mg/day or micronized estradiol 17β 0.5 mg/day or transdermal estradiol 17β 0.025 mg/day
  - Ultra-low dose: micronized estradiol 17β 0.025 mg/day or transdermal estradiol 17β 0.014 mg/day
  - Micronized progesterone 100 mg/day can be used as progestin. Alternative: medroxyprogesterone acetate (MPA) 2.5 mg/day. Combination estradiol/progestin transdermal treatments have either levonorgestrel or norethindrone as progestin source. Although not approved for postmenopausal women, the levonorgestrel intrauterine system (IUS) has been used.
  - Bazedoxifene + conjugated estrogens for relief of vasomotor symptoms and bone loss prevention

- Long-term use of hormone replacement therapy (HRT) has more risks than benefits in healthy postmenopausal women, including but not limited to:
  - Cardiovascular disease
  - Breast, ovarian, and endometrial cancer
  - Venous thromboembolism

- Less worrisome side effects include breast tenderness, vaginal bleeding, bloating, and headaches.

- MenoPro app is free for iPhones and iPad from The North American Menopause Society (NAMS). It has two modes: one for clinicians and one for patients to aid in shared decision-making. It allows users to progress through questions to evaluate cardiovascular and reproductive organ cancer risk (4).

- American College of Obstetricians and Gynecologists (ACOG) recommends HT should be individualized with lowest effect dose given for the shortest duration of time needed to relieve vasomotor symptoms. Lower doses have similar symptom reduction profiles for many patients. Results of ultra-low-dose regimens are mixed.

- Precautions:
  - Women’s Health Initiative (WHI) study demonstrate women who take CEE with MPA versus placebo had increased congenital heart disease events, invasive breast cancer, stroke, pulmonary embolism, dementia, gallbladder disease, urinary incontinence; benefits included decreased hip fractures, diabetes, and vasomotor symptoms.
  - Breast cancer risk not seen until 5 years of use
  - Women on estrogen alone had no increased risk of invasive breast cancer, but did increase abnormal mammograms requiring follow-up investigations
  - HRT should not be used for cardioprotective benefit as risk outweighs benefit.
– Higher doses of estrogen can cause hypercoagulability, breast tenderness, gallbladder disease, and hypertension.
– Contraindications to HT:
  o Estrogen-dependent malignancies
  o Unexplained uterine bleeding
  o History of thromboembolism or stroke
  o Coronary artery disease
  o Active liver disease

• For osteoporosis: Women with a history of hip or vertebral fracture or personal history of osteoporosis should be treated with one of the following:
  – Bisphosphonates to inhibit osteoclast action and resorption of bone:
    o Alendronate: 70 mg/week or 10 mg/day
    o Risedronate: 35 mg once a week or 5 mg/day
    o Zoledronic acid: 5 mg IV annually
    o Ibandronate: 150 mg/month PO or 3 mg IV q3mo
  – Selective estrogen receptor modulators (SERMs) selectively inhibit or stimulate estrogen like action with stimulation of osteoblasts:
    o Raloxifene: 60 mg/day
      - Decreases the risk of vertebral fracture
    o Bazedoxifene + conjugated estrogens (0.45 mg/20 mg)
      - FDA approved for moderate to severe vasomotor symptoms and osteoporosis
  – Denosumab (60 mg SC every 6 months) is a monoclonal antibody that prevents RANKL (receptor activator of nuclear factor kappa-B ligand) from accelerating osteoclast generation; reduces incidence of vertebral and hip fractures in postmenopausal women
  – Parathyroid hormone—rarely used due to the adverse effect on bone but shown to reduce fracture risk in menopausal women with osteoporosis

• For vulvar/vaginal atrophy:
  – Topical estrogen therapy (ET) reverses vaginal atrophy, enhances blood flow, and reduces UTI. Continue for as long as distressing symptoms remain. Initiate treatment daily for 1 to 2 weeks and then decrease to 2 times weekly. Comes as estradiol cream, tablet, or ring. No evidence of difference in efficacy between various intravaginal estrogenic preparations.
    Apply vaginally:
    o Estradiol cream 0.01% (1 g), conjugated estrogen 0.625 mg/g (0.5 g), vaginal tablet (10 μg) used twice weekly, or vaginal ring (7.5 μg daily lasting for 3 months)
    o Ospemifene: 60 mg PO daily; SERM for moderate to severe dyspareunia associated with vaginal atrophy
  – Nonestrogen vaginal lubricant may be as effective as topical estrogen for some.

• Although there is no increased risk of endometrial hyperplasia or EAC, women with bleeding on these treatments should be evaluated with TVUS or EMB. Patients with h/o hormone-dependent cancer should meet with a gynecologist before using medication.

Second Line
Nonhormonal treatments may be helpful to treat vasomotor symptoms in women who wish to or need to avoid HT (e.g., breast cancer):
• Paroxetine (7.5 mg/day) is approved for treatment of vasomotor symptoms. This selective serotonin reuptake inhibitor (SSRI) demonstrated modest decrease in hot flashes.
• Other SSRI/SRNIs: Venlafaxine (37.5 to 75.0 mg/day) or fluoxetine (20 mg/day) and
citalopram (20 mg/day) shown to reduce hot flushes as compared to placebo.
- Gabapentin (300 to 900 mg/day) shown to have an effect on lowering hot flashes compared to placebo.
- Clonidine (0.05 mg BID) may be used to treat mild hot flashes, less effective than SSRI/SRNIs.
- Note that most trials of second-line therapies have been brief (i.e., a few months).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Trials of nonprescribed therapies are difficult to interpret due to variability of components and doses:
- Soy isoflavone in placebo-controlled trials showed a mixed effect in reducing hot flashes.
- Red clover, black cohosh, reflexology, aerobics, and magnet therapy showed no impact on hot flashes when compared with placebo.
- Small clinical trials of evening primrose, dong quai, ginseng, and wild yam do not support use for relief of hot flashes.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
A DEXA scan is indicated at age 65 years for all women and for younger women with risk equivalent to age 65 years.

**DIET**
Calcium-rich diet and vitamin D supplementation (800 to 1,200 IU/day). Calcium supplements may have adverse effects including increased risk of kidney stone and increased risk of cardiac events.

**PATIENT EDUCATION**
Encourage lifestyle modifications:
- Smoking cessation, reducing alcohol intake
- Weight-bearing exercise >30 minutes, 3 times weekly
- Healthy diet to maintain appropriate weight
- Address cardiovascular risk factor modification.

**PROGNOSIS**
If untreated:
- Ultimate disappearance of vasomotor symptoms
- Worsening of vaginal/vulvar atrophy
- Osteoporosis: possible fractures of the hip, vertebrae, and wrists

**COMPLICATIONS**
- Osteoporosis: At menopause, women have accelerated bone loss up to 3–5% per year for 5 to 7 years.
- Increased risk of CVD following menopause
REFERENCES

ADDITIONAL READING

CODES
ICD10
- E28.310 Symptomatic premature menopause
- N95.1 Menopausal and female climacteric states
- Z78.0 Asymptomatic menopausal state

CLINICAL PEARLS
- Menopause is usually diagnosed by history alone.
- HT can be used short term for relief of moderate to severe vasomotor symptoms but should not be used for long-term prevention of CVD.
DESCRIPTION
- The current preferred terminology for menorrhagia is “heavy menstrual bleeding” (HMB).
- HMB is an excessive amount (≥80 mL/cycle, compared with normal average of 30 to 60 mL/cycle) or periods lasting longer than 7 days.
- Clinically, HMB is an excessive menstrual blood loss which interferes with the woman’s physical, emotional, social, and material quality of life.
- Other patterns of abnormal uterine bleeding (AUB) which may overlap with HMB include:
  - Intermenstrual bleeding (IMB; previously metrorrhagia): bleeding between regular menses
  - Polymenorrhea: menstrual cycle length <21 days
- HMB applies only to ovulatory menses and is a subcategory of “abnormal uterine bleeding.”
- A classification system called the PALM-COEIN was developed to describe AUB in women of reproductive age.
- It includes the structural causes (polyp, adenomyosis, leiomyoma [submucosal or other myoma], and malignancy and hyperplasia) and nonstructural causes (coagulopathy, ovulatory dysfunction, endometrial, iatrogenic, and not yet classified).
- System affected: reproductive

Epidemiology

Prevalence
- HMB affects >10 million American women each year or about one out of every five women (1).
- Puberty and the perimenopause typically are associated with AUB and are considered to be physiologic in these circumstances (2).

Pediatric Considerations
- Genital bleeding before puberty is not menstrual bleeding by definition and requires further evaluation.
- Due to immaturity of the hypothalamic-pituitary-ovarian axis, adolescents are at risk of irregular bleeding and HMB.
- Adolescents with HMB should be evaluated for possible bleeding disorders, especially von Willebrand disease (3)[C].

Pregnancy Considerations
Bleeding in pregnancy is not menstrual bleeding by definition and requires further evaluation. Pregnancy test should be obtained as part of the evaluation of AUB.

Geriatric Considerations
Menopause is diagnosed after 12 months of amenorrhea in the absence of other causes and is typically preceded by irregular bleeding. All postmenopausal bleeding requires additional workup for malignancy.
ETIOLOGY AND PATHOPHYSIOLOGY
- No cause is identified in about 1/2 of patients.
- Bleeding disorders
  - Von Willebrand disease
  - ITP and other platelet disorders
  - Factor deficiencies
  - Medication side effect most commonly related to anticoagulants including warfarin
  - Renal failure leading to uremic platelet dysfunction
  - Cirrhosis leading to coagulopathy
- Uterine fibroids, typically submucosal
- Endometrial polyps
- Hypothyroidism
- Iatrogenic causes including copper intrauterine device (IUD)
- Endometriosis
- Adenomyosis
- Pelvic inflammatory disease
- Some causes more typically presenting as irregular menstrual bleeding include:
  - Polycystic ovarian syndrome (PCOS)
  - Hypothalamic-pituitary dysfunction, often postmenarchal or during menopausal transition
  - Endometrial or ovarian neoplasia
  - Some forms of hormonal birth control
  - Hyperthyroidism
  - Hyperprolactinemia
- HMB has been associated with increased production and sensitivity to prostaglandins.

GENERAL PREVENTION
- Combined oral contraceptives may prevent HMB, particularly when progesterone is dominant. Lower estrogen doses result in less menstrual bleeding.
- NSAIDs including ibuprofen inhibit prostaglandin production and result in decreased blood loss and pain during menses.
- Progesterone-only contraceptives may reduce overall blood loss but often result in irregular bleeding.

COMMONLY ASSOCIATED CONDITIONS
Iron deficiency anemia

DIAGNOSIS

HISTORY
- Suggestive historical features for HMB:
  - Bleeding substantially heavier than patient’s usual flow
  - Changing sanitary products every 1 to 2 hours or the need to change protection overnight
  - Menses lasting >7 days
  - Passage of clots larger than a quarter in diameter
- Symptoms that suggest bleeding is ovulatory:
  - Regular menstrual interval
– Midcycle pain (mittelschmerz)
– Premenstrual symptoms: breast soreness, mood changes

Abdominal pain or cramps at other times of the cycle may be associated with structural causes:
– Polyps
– Adenomyosis
– Leiomyoma
– Ovarian tumors

Symptoms that suggest an underlying bleeding disorder include:
– Epistaxis
– Mucosal bleeding (e.g., gums)
– Easy bruising
– Family history of bleeding disorder

Review of medications, with particular attention to contraceptive and anticoagulant medication

Other medical conditions that may relate to HMB:
– Renal or hepatic disease
– Thyroid disease

Evaluate for symptoms of anemia including fatigue and dyspnea.

**PHYSICAL EXAM**

– Prompt assessment for signs of hemodynamic instability, including orthostatic vital signs (4)
– Thyroid nodule or goiter suggests thyroid disease.
– Signs of a bleeding disorder include petechiae and ecchymoses.
– Pelvic examination, including speculum and bimanual examination, may reveal the following:
  – Cervical or vaginal source of bleeding
  – Pelvic or adnexal mass
  – Evidence of reproductive tract infection such as cervical motion tenderness
  – Uterine enlargement
– Hirsutism, acne, and obesity are suggestive of PCOS.

**DIFFERENTIAL DIAGNOSIS**

– Normal menses
– Anovulatory bleeding
– IMB
– Complications of pregnancy
  – Spontaneous abortion
– Other sources of bleeding:
  – Cervical
  – Vaginal
  – Gastrointestinal

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

– Pregnancy test
– CBC to assess for:
  – Anemia
  – Thrombocytopenia
  – Leukocytosis may suggest infection.
Labs to consider in select cases:
- Coagulation panel for evaluation for bleeding disorder in adolescent or adult with history suggestive of bleeding disorder (2)[A]
- Workup of anovulatory bleeding may also include prolactin, androgens, FSH, LH, and estrogen.
- Appropriate cervical cancer screening
- Evaluation for infection including gonorrhea and chlamydia (2)[B]

Imaging should be obtained based on clinician judgment and should begin with transvaginal ultrasonography.
- Transabdominal ultrasonography should be performed if transvaginal approach does not provide full assessment of anatomy.
- Some experts recommend transvaginal ultrasonography as the initial screening test for AUB and MRI as a second-line test to be used when the diagnosis is inconclusive, when further delineation would affect patient management, or when coexisting uterine myomas are suspected (2)[C].
- Endometrial biopsy should be performed in patients with AUB who are >45 years as a first-line test (2)[C].

Follow-Up Tests & Special Considerations
- Saline infusion sonohysterography is recommended if ultrasound suggests intracavitary pathology and is more sensitive and specific than transvaginal ultrasound (2)[C].
  - Sonohysterography is superior to transvaginal ultrasonography in the detection of intracavitary lesions, such as polyps and submucosal leiomyomas (2)[A].
- Hysteroscopy can be performed if direct visualization is desired.

Diagnostic Procedures/Other
Endometrial biopsy to assess for malignancy and hyperplasia is recommended in some situations including (2,4)[C]:
- Any AUB, including HMB, after age 45 years in an ovulatory (premenopausal) woman
- Woman <45 years with persistent or refractory AUB, risk factors such as unopposed estrogen exposure, or concerning endometrial imaging

TREATMENT
GENERAL MEASURES
Treat underlying conditions (e.g., hypothyroidism) when possible.

MEDICATION
First Line
- For acute control of severe bleeding (5):
  - Obtain IV access and consider blood transfusion or clotting factor administration.
  - Estrogen, conjugated equine: 25 mg IV every 4 to 6 hours for 24 hours
  - Monophasic combined oral contraceptive that contains 35 µg ethinyl estradiol: 3 times per day for 7 days
  - Medroxyprogesterone acetate: 20 mg orally 3 times per day for 7 days
Tranexamic acid: 1.3 g orally or 10 mg/kg IV 3 times per day for 5 days, antifibrinolytic agent

For less severe bleeding (typical case) or after control of acute bleeding has been achieved (5):
- Levonorgestrel IUD (Mirena IUD): typically results in light bleeding or amenorrhea with patient satisfaction similar to hysterectomy and endometrial ablation (6)[A]
- Combination estrogen-progestin oral contraceptive: may be prescribed in cyclic, extended, or continuous dosing and typically results in regular, lighter, and less painful menses
- Depot medroxyprogesterone acetate: 150 mg/1 mL IM every 3 months, typically results in amenorrhea or light irregular bleeding
- Tranexamic acid: 1.3 g orally for 5 days during menses; antifibrinolytic agent that is option for women who desire nonhormonal treatment
- NSAIDs (e.g., naproxen, mefenamic acid, ibuprofen) can reduce blood loss and dysmenorrhea. Those with bleeding disorders or platelet function abnormalities should avoid NSAIDs (5).

**Second Line**
- Noncontraception estrogen-progestin oral contraceptives (ultra-low-dose estrogen): may be considered when a relative contraindication to estrogen is present
- Oral progestins: multiple formulations and dosing; typically used in women who have contraindications to estrogen or are trying to conceive

**SURGERY/OTHER PROCEDURES**
- Dilation and curettage can be considered in the setting of acute severe bleeding.
- For women who desire fertility, myomectomy may be considered for treatment of uterine leiomyomas (fibroids).
- For women who do not desire fertility, consider endometrial ablation, uterine artery embolization, or hysterectomy.
- Conservative surgery (i.e., myomectomy, endometrial ablation, or uterine artery embolization) is more effective for controlling bleeding symptoms at 1 and 2 years than oral medications or the levonorgestrel-releasing IUD, but by 5 years, there is no difference in long-term results or patient satisfaction (1)[B].
  - Patients who undergo endometrial ablation still require contraception.
  - Uterine artery embolization is used to treat uterine leiomyomas.
- In women of reproductive age with chronic HMB, hysterectomy is the most effective treatment for controlling symptoms (1).
  - Hysterectomy is curative but with more severe adverse effects and is typically reserved for failure of medical management or presence of another indication such as malignancy (1).

**ONGOING CARE**

**DIET**
Iron supplementation may help correct for increased blood loss.

**PATIENT EDUCATION**
Patient and provider should engage in informed decision making with understanding of treatment risks and benefits.
PROGNOSIS
Most patients respond well to medical management, and surgical interventions are curative options in appropriate cases. Surgical interventions (hysterectomy or conservative surgeries) are initially more effective and satisfactory than medical treatments, but that the levonorgestrel-releasing intrauterine system yields similar long-term results and patient satisfaction compared with conservative surgical interventions (1).

COMPLICATIONS
- Iron deficiency anemia
- Acute severe blood loss

REFERENCES

CODES
ICD10
- N92.0 Excessive and frequent menstruation with regular cycle
- N92.3 Ovulation bleeding
- N92.2 Excessive menstruation at puberty

CLINICAL PEARLS
- Women with HMB are at high risk for iron deficiency anemia.
- A thorough menstrual history is critical to differentiate HMB from similar conditions including anovulatory bleeding.
- Teenagers presenting with HMB should be evaluated for an underlying bleeding disorder.
- All postmenopausal bleeding and bleeding during pregnancy requires additional workup.
- The levonorgestrel (Mirena, Kyleena, generics) IUD may be used for HMB and is associated with high patient satisfaction rates.
MESOTHELIOMA
Khalid Bashir, MD

BASICS

DESCRIPTION
- Mesothelioma is a rare, aggressive malignancy of the mesothelial or serous tissues primarily found in the pleura (65–70%) or peritoneum (20–33%), tunica vaginalis (1–2%) or pericardium (1–2%) (1).
- Inhalation of asbestos is the predominant cause of mesothelioma, most often from occupational exposure.

EPIDEMIOLOGY

Incidence
- The incidence in the United States is decreasing, but it is increasing in other countries, particularly Great Britain and Australia.
- It is expected that rates of mesothelioma will start to drop after 2015 to 2025 related to reduced exposure and better understanding of the process of development of mesothelioma after exposure to asbestos (2).
- The incidence increases with age, peaking in the 6th decade, with 70% of pleural disease occurring in males. Peritoneal involvement is slightly higher in women.
- Main risk factor is asbestos exposure, but tumors have arisen after prior radiation or exposure to talc, erionite, or mica or in patients with familial Mediterranean fever and diffuse lymphocytic leukemia.

Prevalence
There are 3,300 cases of mesothelioma diagnosed in the United States annually (3).

ETIOLOGY AND PATHOPHYSIOLOGY

- The predominant cause of mesothelioma is exposure to asbestos (hydrated magnesium silicate fibrous minerals).
- There is a long latent period of up to 44 years between exposure and development of mesothelioma (2).
- Inhaled or ingested asbestos fibers become trapped in pleural or peritoneal membranes, causing changes of irritation and inflammation.

Genetics
Loss of nuclear deubiquitinase BAP1 is associated with incidence of mesothelioma in some families as well as with other cancers such as melanoma.

RISK FACTORS
- The predominant risk factor is exposure to asbestos.
- Occupational exposures involve mining or milling of fibers, work with textiles, cement, friction materials, insulation, or shipbuilding.
- Nonoccupational exposures include renovation or destruction of asbestos-containing buildings, exposure to industrial sources in the community or natural geologic sources, or exposure to
soiled clothing of asbestos workers (1,3,4).
- Radiation exposure, smoking, proximity to naturally occurring asbestos deposits, or inhalation of other fibrous silicates can contribute to malignant mesothelioma.

**GENERAL PREVENTION**
- Avoidance of asbestos exposure
- Strict adherence to protective protocols for workers in buildings where asbestos is found
- Continued aggressive remediation of asbestos-affected buildings and homes

**DIAGNOSIS**

**HISTORY**
- Symptoms are usually nonspecific and occur when disease is advanced. General fatigue, night sweats, and weight loss may be present.
- Pleural mesothelioma presents with gradual onset of pulmonary symptoms, chest pain, dyspnea, and cough.
- Peritoneal disease presents with vague abdominal pain, increased abdominal girth, nausea, anorexia, and weight loss.

**PHYSICAL EXAM**
- Pulmonary findings consistent with pleural effusion, including decreased breath sounds, dullness to percussion, and asymmetric chest wall expansion, are found.
- Abdominal findings consistent with ascites, including abdominal distension, fluid wave, and tenderness, are found.

**DIFFERENTIAL DIAGNOSIS**
- Pleural mesothelioma’s differential diagnosis includes inflammatory reactions (empyema, pleural effusion), metastatic tumor from other sites, fibrosarcoma, malignant fibrous histiocytoma, sarcomatoid carcinoma, and synovial sarcoma.
- Peritoneal mesothelioma’s differential diagnosis includes peritoneal carcinomatosis, serous peritoneal carcinoma, ovarian carcinoma in women, lymphomatosis, and tuberculous peritonitis.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- At present, there is no tumor marker or serum chemistry that is of value in establishing the diagnosis of mesothelioma.
- Biomarkers that may be elevated in mesothelioma include fibulin-3, mesothelin, and osteopontin. However, they do not have an established role in diagnosis or monitoring response to therapy (2)[A].
- Pleural mesothelioma diagnosis requires tissue. Thoracentesis for cytology and closed pleural biopsy may be adequate, but often, more invasive procedures such as video-assisted thoracoscopic surgery (VATS) is needed to obtain an adequate specimen (1,2)[A].

**Follow-Up Tests & Special Considerations**
Seeding of biopsy sites and tracks may occur in mesothelioma, which can be prevented with prophylactic radiation therapy to the scar or biopsy site (5)[A].
Diagnostic Procedures/Other
- Computed tomography, magnetic resonance imaging, positron emission tomography, or integrated PET-CT helps with clinical staging in pleural and peritoneal disease (1,2,3,4,5)[A].
- Mediastinoscopy, bronchoscopy, and laparoscopy can assist in full surgical staging of pleural disease (2)[A].
- Endobronchial ultrasound for staging is under investigation for pleural disease.

Test Interpretation
- The tumor, node, metastasis (TNM) staging system is most commonly used, although some centers use other staging systems.
- Butchart staging system is the oldest and still used in some parts of the world.
- Brigham staging system attempts to define resectability and lymph node involvement.

TREATMENT

GENERAL MEASURES
- A multidisciplinary team is important in management and should include thoracic surgery, oncology, pathology, pulmonary, and radiology for patient-specific planning of management.
- Pain assessment and control should follow principles of cancer pain management (5).

MEDICATION

First Line
- In pleural disease, combined therapy with cisplatin + gemcitabine or cisplatin + pemetrexed are associated with longer median survival than cisplatin alone (2,4)[A].
- Addition of bevacizumab to cisplatin and pemetrexed in pleural disease is also been looked at as an alternative strategy in select population.
- Vinflunine is showing some potential for first-line treatment in pleural disease (2)[A].
- Hyperthermic intraoperative or early postoperative intraperitoneal chemotherapy can increase drug concentration in the peritoneum and decrease systemic side effects. Use cisplatin, mitomycin C, fluorouracil, doxorubicin, and/or paclitaxel (1,2),(3)[A]

Second Line
- Palliative benefit in pleural disease with mitomycin C, vinblastine, cisplatin, and pemetrexed alone or in combination with carboplatin (2,3,4)[A]
- Systemic therapy for peritoneal disease may include pemetrexed + cisplatin; vinorelbine or gemcitabine alone or in combination (1,5)[A]

ISSUES FOR REFERRAL
- Pulmonary, oncology, and surgical follow-up after discharge as indicated
- Anger and depression may require psychological or psychiatric services (5).

ADDITIONAL THERAPIES
- Immunotherapy in pleural disease uses humanized anti-CB3 AB (OKT3), cytotoxic T lymph (CTL), interferon α-2a, and autovaccine in advanced disease (1,2,3,4,5).
- Gene therapy
- Photodynamic therapy
- Radiotherapy in some cases of pleural disease
Vascular endothelial growth factor (anti-VEGF-2) in combination with chemotherapy (2) – Vaccines are under study (5).

SURGERY/OTHER PROCEDURES
- For pleural mesothelioma, the role of surgery is not as clear cut. Pleurectomy with tumor decortication and extrapleural pneumonectomy reduces the tumor load, but there remains no clear effect on mortality (2,4,5).
- Radical resection of the peritoneum and cytoreductive surgery is associated with a better prognosis (1).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Based on overall condition
- IV fluids as indicated by general condition
- Nursing as indicated by condition
- Discharge criteria as indicated by general condition

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Smoking cessation
- Immunization for pneumococcal pneumonia and influenza

Patient Monitoring
Monitor for paraneoplastic phenomenon, including fever, thrombocytosis, malignancy-related thrombosis, hypoglycemia, and rare Coombs-positive hemolytic anemia.

DIET
No specific restrictions

PROGNOSIS
- Prognosis is based on gender, stage, and level of completeness of cytoreduction.
- Poorly differentiated tumor grade, failure to undertake surgical resection, advanced age, and male gender are all independent predictors of poorer prognosis (2,3).
- Average survival is 17 to 92 months, with 5-year survival rate at 63%.

COMPLICATIONS
Relapses and progression, infection and dysphagia

Geriatric Considerations
Age >65 years is associated with significantly increased morbidity and mortality.

Pediatric Considerations
Rarely a pediatric issue because most disease occurs after the 5th decade of life

Pregnancy Considerations
Rarely an issue with pregnancy because most disease occurs after the 5th decade of life

REFERENCES

**CODES**

**ICD10**
- C45.1 Mesothelioma of peritoneum
- C45.2 Mesothelioma of pericardium
- C45.0 Mesothelioma of pleura

**CLINICAL PEARLS**
- Mesothelioma remains a rare but universally fatal disease in part due to long latency.
- Multimodal treatment has decreased recurrence rates and has extended survival time.
- Main risk factor is asbestos exposure, but tumors have arisen after prior radiation or exposure to talc, erionite, or mica or in patients with familial Mediterranean fever and diffuse lymphocytic leukemia.
**METABOLIC SYNDROME**
Naomi Parrella, MD, FAAFP, Dipl. ABOM

### BASICS

**DESCRIPTION**
- Cluster of progressive metabolic abnormalities demonstrating insulin resistance, a proinflammatory, and prothrombotic state that manifest with at least three of:
  - Increased waist circumference (WC)
  - Elevated blood pressure (BP)
  - Elevated triglycerides (TG) ≥150 mg/dL or treatment
  - Decreased high-density lipoprotein (HDL-C) in men <40 mg/dL, women <50 mg/dL
  - Elevated fasting glucose ≥100 mg/dL
- Metabolic syndrome (MetS) predicts increased risk for type 2 diabetes mellitus (T2DM), cardiovascular disease, stroke, nonalcoholic fatty liver disease (NAFLD), certain cancers, and all-cause mortality.

### EPIDEMIOLOGY

**Incidence**
Incidence of MetS parallels the incidence of obesity and T2DM.

**Prevalence**
- As of 2012, MetS affects 34.2% of U.S. adults aged ≥18 years; increasing with the aging population and the prevalence of obesity.
- Predominant sex (U.S.): female (34.9%) > male (33.4%)
- Prevalence increases with age with >50% of person >70 years old with MetS
- Predominant ethnicity (U.S.): non-Hispanic white men and women and non-Hispanic black women

**Pediatric Considerations**
- Obese children and adolescents are at high risk of MetS. Risk factors in children and adolescents include ethnicity; heredity; maternal gestational diabetes; low birth weight; childhood excess weight gain and obesity; endocrine abnormalities, including polycystic ovarian syndrome (PCOS); and poor health habits (eating refined carbohydrates, drinking daily fruit juice or sugar sweetened beverages, sedentariness, inadequate sleep).
- International Diabetes Federation (IDF) consensus report defined criteria in three age groups (6 to ≤10 years; 10 to ≤16 years; 16+ years, adult criteria applicable). Obesity defined by WC ≥90th percentile; rest of the diagnostic criteria (TG, HDL-C, hypertension [HTN], and fasting blood sugar/T2DM) are largely the same as in adults for children ≥10 years, with some exceptions, and warrant treatment to optimize diet and physical activity.
- Clinical significance of MetS in pediatric population is not well established using these criteria. WC alone is better than using IDF criteria to predict development of MetS, abnormal BP, dyslipidemia, and insulin resistance. Focus on healthy weight management and promoting healthy lifestyle habits for the whole family rather than diagnosis.

### ETIOLOGY AND PATHOPHYSIOLOGY
Increase in intra-abdominal and visceral adipose tissue
Adipose tissue dysfunction, hormone dysregulation, insulin resistance, and leptin resistance
Decreased levels of adiponectin, an adipocytokine, known to protect against T2DM, HTN, atherosclerosis, and inflammation
Abnormal fatty acid metabolism, endothelial dysfunction, systemic inflammation (increased IL-6, tumor necrosis factor-α [TNF-α], resistin, CRP), oxidative stress, elevated renin-angiotensin system activation, and a prothrombotic state (increased tissue plasminogen activator inhibitor-1) are also associated.

The main etiologic factors are the following:
- Central obesity (particularly abdominal)/excess visceral adipose tissue
- Insulin resistance
- Other contributing factors:
  - Advancing age
  - Proinflammatory state
  - Genetics, epigenetics, parental obesity
  - Sedentary lifestyle
- Endocrine (e.g., postmenopausal state)
- Prescription medications (e.g., corticosteroids, antipsychotics, β-blockers)

**Genetics**
Genetic factors contribute to causation. Most identified genes are transcription factors or regulators of transcription and translation with evidence of complex interactions between genetics and environment. Parental obesity at the time of conception may affect epigenetic changes that may promote MetS in offspring.

**RISK FACTORS**
- Obesity/intra-abdominal obesity, insulin resistance
- Childhood obesity
- Older age, postmenopausal status
- Ethnicity
- Family history
- Physical inactivity
- High-carbohydrate diet
- Sugar-sweetened beverages daily
- Smoking
- Low socioeconomic status
- Alteration of gut flora
- Poor sleep, obstructive sleep apnea

**GENERAL PREVENTION**
- Maintenance of healthy weight or in those at metabolic risk and/or with an enlarged WC, aim for a weight loss of 5% or greater
- Built environment to promote healthy lifestyle choices and reduce sedentary time
- Regular and sustained physical activity (1)[A]
- Diet low in processed carbohydrates and sugars (2)[A]; avoidance of sugar-sweetened beverages

**COMMONLY ASSOCIATED CONDITIONS**
- PCOS
- Acanthosis nigricans
- NAFLD, nonalcoholic steatohepatitis
- Obstructive sleep apnea (OSA)
- Osteoarthritis
- Depression and anxiety
- Cognitive impairment
- Heartburn and gastroesophageal reflux disease
- Gallstones
- Chronic renal disease
- Erectile dysfunction
- Hyperuricemia and gout
- Vitamin D deficiency
- Subclinical hypothyroidism

DIAGNOSIS

HISTORY
Identifying risk factors
- Family history of MetS, T2DM, and cardiovascular disease
- Symptoms indicating cardiovascular disease or diabetes or PCOS
- Comprehensive lifestyle history:
  - Diet, including timing (night eating) and intake of carbohydrates especially added sugars and caloric beverages
  - Weight history, including onset of obesity and previous weight loss attempts
  - Exercise regimen, daily activity level
  - Alcohol intake
  - Sleep patterns, duration, and quality
- Cigarette smoking
- Cardiovascular risk assessment tool

PHYSICAL EXAM
- Waist circumference with abdominal obesity: men ≥102 cm, women ≥88 cm in white, African, Hispanic, and Native American populations, and ≥90 cm and ≥80 cm respectively in East Asian and South Asian populations
- BP ≥130/85 mm Hg or treatment
- Additional exam findings suggestive of insulin resistance such as acanthosis nigricans, hirsutism

DIFFERENTIAL DIAGNOSIS
- Prediabetes, T2DM are associated with MetS
- OSA, PCOS, thyroid abnormalities, Cushing syndrome, medication effect (especially psychotropic, chronic steroids, β-blockers, and thiazide diuretic medications) may also be considered in the differential.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Fasting TGs ≥150 mg/dL or treatment
- HDL: men <40 mg/dL, women <50 mg/dL or treatment
- Fasting glucose ≥100 mg/dL or treatment or hemoglobin A1C >5.7%

Follow-Up Tests & Special Considerations
- Body composition measurements to assess lean tissue and fat mass. Athletes and bodybuilders may demonstrate elevated BMI despite low body fat. Older and more frail individuals with sarcopenic obesity may demonstrate normal BMI.
- Formal 75-mg oral glucose tolerance test or hemoglobin A1C for diagnosis of impaired glucose tolerance (IGT) or prediabetes.
- Consider measurement of fasting insulin levels and/or calculation of TGA:HDL ratio (elevated in insulin resistance).
- May consider further cardiovascular disease risk assessment such as advanced lipid profile analysis, hs-CRP, or homocysteine as well as coronary calcium test or carotid intima-media thickness (CIMT) measurement.
- Liver function tests to assess for NAFLD
- Consider evaluation for OSA.
- Consider evaluation for vitamin D deficiency.
- Consider evaluation for hyperuricemia and microalbuminuria.

Diagnostic Procedures/Other
- Home BP monitoring or 24-hour BP monitoring may be used to rule out white coat HTN.
- ECG, stress test
- Ultrasound of liver to evaluate for fatty liver.

TREATMENT
Primary therapeutic goal is to prevent or reduce obesity and risk factors. Aggressive lifestyle modification (diet and exercise) is considered first-line therapy and most clinically effective. >7% weight loss and/or significant dietary carbohydrate restriction can improve/reverse risk factors associated with MetS (2)[A].

GENERAL MEASURES
- Aggressive treatment of individual risk factors
- Incorporate healthy dietary recommendations (see below).
- Increase daily physical activity (1)[A].
- Stop smoking.
- Avoid excess alcohol intake.
- Avoid sugar-sweetened beverages. Note that some nonnutritive sweeteners may also alter sweet-taste receptors, gut hormone secretion, and promote gut microbiome imbalance and insulin resistance (3).
- Promote a Mediterranean and/or a low carbohydrate diet (2)[A], low glycemic load diet, avoiding sugars and starchy carbohydrates.
- Increase leafy green vegetable consumption.
- Consider use of time-restricted feeding (4)[A] (avoid in individuals with history of eating disorders).
Maintain healthy sleep patterns and regular stress management.
Bariatric surgery is first line if BMI >40 or BMI >35 with obesity-related comorbidities

MEDICATION
Consult clinical guidelines for the pharmacologic treatment of obesity, BP, dyslipidemia, HTN, IGT, prediabetes, and diabetes.
Optional: Metformin to prevent T2DM. If CAD or T2DM is already evident, treat as per guidelines. Use acetylsalicylic acid 81 mg for primary prevention as indicated per U.S. Preventive Services Task Force if benefits outweigh bleeding risk.

First Line
Lifestyle modification alone because initial strategy is applicable to individuals with low 10-year risk for coronary artery disease (CAD). In individuals with higher 10-year risk, more aggressive risk factor–based approach is recommended in addition to lifestyle modifications:

- Obesity: Lifestyle changes are the cornerstone of treatment. Aim for a <5–10% weight reduction, which is associated with significant benefits. See section on “Obesity.”
- Physical activity: Exercise improves MetS (1)[A]. 30 to 60 minutes of moderate-intensity aerobic activities such as brisk walking 5 to 7 days/week; increase in daily lifestyle activities and resistance training 1 to 2 days/week. In patients with established CAD, assess detailed history of physical activity and exercise tolerance to guide activity prescription. Advise medically supervised programs for high-risk population (recent acute coronary syndrome [ACS], congestive heart failure, recent revascularization). Cumulative exercise time over the day contributes to health benefit.
- Tobacco use: See section on “Smoking Cessation.”
- OSA: See section on “Obstructive Sleep Apnea.”
- Dyslipidemia: See section on “Dyslipidemia.”
- HTN: Aim for similar targets to patients with diabetes. See section on “Hypertension.” β-Blockers may lead to weight gain and worsen MetS.
- IGT and/or prediabetes: intensive lifestyle interventions (ILI) +/- Metformin to decrease the risk of progression to T2DM.

ISSUES FOR REFERRAL
- Obesity management/nutrition therapy
- Liver function tests suggesting liver disease
- Suspected OSA
- Weight-related mental health concerns (e.g., binge eating disorder)

SURGERY/OTHER PROCEDURES
Bariatric surgery can treat MetS in severely obese patients who have failed trials of lifestyle modification and pharmacotherapy; surgery is recommended in appropriate individual if body mass index (BMI) >40 or BMI >35 with obesity-related comorbidities.

COMPLEMENTARY & ALTERNATIVE MEDICINE
There is evidence emerging for the use of resveratrol in prevention and treatment of MetS. Fish oil is associated with increasing insulin sensitivity; insufficient or no evidence on the use of chromium, cinnamon, green tea, L-carnitine, plant sterols, or zinc supplementation for improved insulin sensitivity.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Regular exercise will improve all components of MetS. Cumulative small periods of exercise over the day provide significant health benefits. Encourage small increases in physical activity over time (1)[A].
- Encourage replacing sedentary activity choices (e.g., sitting at desk, driving car, taking elevator, and the like) to more active ones (e.g., standing desk, walking, cycling, stationary walking during commercials).
- Weight reduction to improve abdominal obesity is a primary goal achieved by dietary modification and increased physical activity.
- Regular monitoring of weight, WC, and BP. Fasting TG, HDL, and sugar levels may be routinely monitored to assess progress and to focus treatment efforts.

Patient Monitoring

Especially with significant weight loss, intermittent fasting (4)[A], or low carbohydrate diet (2) [A], monitor for low blood sugars and blood pressure, and de-escalate medications as necessary.

DIET

- Dietary recommendations may include limiting sugars and simple carbohydrates in diet; intermittent fasting or time-restricted feeding (4)[A]; eating a low carbohydrate (2)[A], Mediterranean, or DASH (Dietary Approaches to Stop Hypertension) diet.
- To reduce risk of developing T2DM, encourage increasing intake of vegetables and fiber, limit fruit, and keep alcohol in moderation.
- Avoid refined grains, fruit juice, and sugar-sweetened beverages.

COMPLICATIONS

Progression of CVD and T2DM, an increased risk of NAFLD, stroke, chronic kidney disease, cognitive decline, and an increased risk of developing certain cancers, including breast cancer in women, pancreatic cancer, colon cancer, among others.

REFERENCES

ADDITIONAL READING

SEE ALSO
Diabetes; Hypertension; Obesity; Obstructive Sleep Apnea; Polycystic Ovarian Syndrome (PCOS); Prediabetes

CODES
ICD10
E88.81 Metabolic syndrome

CLINICAL PEARLS
- Consider further evaluation for MetS when history and/or physical exam demonstrates findings consistent with sedentary lifestyle, sleep apnea, increasing WC, elevation of BP or treatment, increased TG:HDL ratio, evidence of insulin resistance, or abnormal screening labs or treatment for lipids or blood glucose.
- Reduction of obesity and cardiovascular risk factors is the cornerstone of management of MetS.
- Consider alternatives for medications known to increase risk of MetS such as atypical antipsychotic medications and chronic steroids.
- Risks associated with MetS may be reduced or resolved by following a diet limiting daily sugars and carbohydrates.
- In addition to regular 30- to 60-minute exercise regimen, there is significant benefit to decreasing sedentariness and increasing cumulative physical activity over the day.
- Aggressive lifelong lifestyle modification is the first line and most potent treatment for all patients.
METATARSALGIA
Ammar Shahid, MD • Marc W. McKenna, MD

BASICS

DESCRIPTION
● Metatarsalgia is defined as pain in the forefoot under one or more metatarsal heads.
● There are three groups:
  – Primary: due to anatomical issues
  – Secondary: due to conditions that increase metatarsal loading via indirect mechanisms, such as chronic synovitis
  – Iatrogenic

EPIDEMIOLOGY

Incidence
Especially common in athletes engaging in high-impact sports (running, jumping, dancing), in rock climbers (12.5%), and in older active adults

Prevalence
Common

ETIOLOGY AND PATHOPHYSIOLOGY
● The 1st metatarsal head bears significant weight when walking or running. A normal metatarsal arch ensures this balance. The 1st metatarsal head normally has adequate padding to accommodate increased forces.
● Reactive tissue can build a callus around the metatarsal head, compounding the pain.
  – Excessive or repetitive stress. Forces are transmitted to the forefoot during several stages (midstance and push off) of walking and running. These forces are translated across the metatarsal heads at nearly 3 times the body weight (1)[C].
  – A pronated splayfoot disturbs this balance, causing equal weight-bearing on all metatarsal heads.
  – Any foot deformity changes distribution of weight, impacting areas of the foot that do not have sufficient padding.
  – Soft tissue dysfunction: intrinsic muscle weakness, laxity in the Lisfranc ligament
  – Abnormal foot posture: forefoot varus or valgus, cavus or equinus deformities, loss of the metatarsal arch, splayfoot, pronated foot, inappropriate footwear
  – Dermatologic: warts, calluses (2)[C]
● Great toe
  – Hallux valgus (bunion), either varus or rigidus
● Lesser metatarsals
  – Freiberg infraction (i.e., aseptic necrosis of the metatarsal head usually due to trauma in adolescents who jump or sprint)
  – Hammer toe or claw toe
  – Morton syndrome (i.e., long 2nd metatarsal)

RISK FACTORS
Obesity
High heels, narrow shoes, or overly tight-fitting shoes (rock climbers typically wear small shoes)
Competitive athletes in weight-bearing sports (e.g., ballet, basketball, running, soccer, baseball, football)
Foot deformities or changes in ROM (e.g., pes planus, pes cavus, tight Achilles tendon, tarsal tunnel syndrome, hallux valgus, prominent metatarsal heads, excessive pronation, hammer toe deformity, tight toe extensors) (2)[C]

Geriatric Considerations
Concomitant arthritis
Metatarsalgia is common in older athletes.
Age-related atrophy of the metatarsal fat pad may increase the risk for metatarsalgia.

Pediatric Considerations
Muscle imbalance disorders (e.g., Duchenne muscular dystrophy) cause foot deformities in children.
In adolescent girls, consider Freiberg infraction.
Salter I injuries may affect subsequent growth and healing of the epiphysis.

Pregnancy Considerations
Forefoot pain during pregnancy usually results from change in gait, center of mass, and joint laxity.
Wear properly fitted low-heeled shoes.

GENERAL PREVENTION
Wear properly fitted shoes with good padding.
Start weight-bearing exercise programs gradually.
Adequate stretching, particularly of the calf muscles
Weight loss if overweight

COMMONLY ASSOCIATED CONDITIONS
Arthritis
Morton neuroma
Sesamoiditis
Plantar keratosis—callous formation

DIAGNOSIS
HISTORY
Pain gradually develops and persists over the heads of one or more metatarsals. Pain is usually on the plantar surface and worse during midstance gait phase.
Pain is often chronic.
Predisposition with pes cavus and hyperpronation
Pain often described as walking with a pebble in the shoe; aggravated during midstance or propulsion phases of walking or running

PHYSICAL EXAM
Point tenderness over plantar metatarsal heads
Pain in the interdigital space or a positive metatarsal squeeze test suggests Morton neuroma.
Plantar keratosis
Tenderness of the metatarsal head(s) with pressure applied by the examiner’s finger and thumb
Erythema and swelling (occasionally)

DIFFERENTIAL DIAGNOSIS
Stress fracture (most commonly 2nd metatarsal)
Morton neuroma (i.e., interdigital neuroma)
Tarsal tunnel syndrome
Sesamoiditis or sesamoid fracture
Salter I fracture in children
Arthritis (e.g., gouty, rheumatoid, inflammatory, osteoarthritis, septic, calcium pyrophosphate dihydrate crystal deposit disease [CPPD])
Lisfranc injury
Avascular necrosis of the metatarsal head
Ganglion cyst
Foreign body
Vasculitis (diabetes)
Bony tumors

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Weight-bearing radiographs: anteroposterior, lateral, and oblique views:
  - Occasionally, metatarsal or sesamoid axial films (to rule out sesamoid fracture) or skyline view of the metatarsal heads to assess the plantar declination of the metatarsal heads: obtained with the metatarsophalangeal (MTP) joints in dorsiflexion (to evaluate alignment)
- Ultrasound and MRI in recalcitrant cases especially if concern for stress fracture
- Only if diagnosis is in question
  - Erythrocyte sedimentation rate or C-reactive protein
  - Rheumatoid factor
  - Uric acid
  - Glucose
  - CBC with differential

Diagnostic Procedures/Other
Plantar pressure distribution analysis may help distinguish pressure distribution patterns due to malalignment.

TREATMENT
Treatment for metatarsalgia is typically conservative.
- Relieve pain.
- Ice initially
- Rest: temporary alteration of weight-bearing activity; use of cane or crutch. For more
physically active patients, suggest an alternative exercise or cross-training:
  – Moist heat later
  – Taping or gel cast
  – Stiff-soled shoes will act as a splint.
  – Gastrocnemius stretching exercises
  • Relieve the pressure beneath the area of maximal pain by redistributing the pressure load of the foot, which can be achieved by weight loss.

MEDICATION
Nonsteroidal anti-inflammatory medications for 7 to 14 days if no contraindications toward use

ISSUES FOR REFERRAL
High-level athletes may benefit from early podiatric or orthopedic evaluation.

ADDITIONAL THERAPIES
• Physical therapy to restore normal foot biomechanics
• Low-heeled (<2 cm height) wide-toe-box shoes
• Metatarsal bars, pads, and arch supports. Metatarsal bars are often more effective than pads.
• Orthotics/rocker bar (Prescriptive orthotics have been shown to be effective treatment.)
• Thick-soled shoes
• Shaving the callus may provide temporary relief. Callus excision is not recommended.
• Corticosteroid injection may benefit interdigital neuritis but should be used with caution because it may cause MTP instability and fat pad atrophy.
• Improve flexibility and strength of the intrinsic muscles of the foot with:
  – Exercises (e.g., towel grasps, pencil curls)
  – Physical therapy to maintain range of motion and restore normal biomechanics

SURGERY/OTHER PROCEDURES
• If no improvement with conservative therapy for 3 months, refer to foot/ankle orthopedic surgeon or podiatrist.
• Surgery may help correct anatomic abnormality: bunionectomy, partial osteotomy, or surgical fusion. Success rates vary depending on procedure.
• Direct plantar plate repair (grade II tear) combined with Weil osteotomy can restore normal alignment of the MTP joint, leading to diminished pain with improved functional scores.
• Callus removal is generally not recommended.
• Morton neurectomy and ultrasound-guided alcohol ablation of Morton neuroma are options (4) [C].
• Surgery only as a last resort if no anatomic abnormality is present.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Magnetic insoles are not effective for chronic nonspecific foot pain.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients generally admitted only for surgery

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
If stress fracture has been ruled out and patient’s condition has not improved >3 months of conservative treatment, consider surgical evaluation.

PATIENT EDUCATION
- Instruct about wearing proper shoes and gradual return to activity.
- Cross-training until symptoms subside. Goal is to restore normal foot biomechanics, relieve abnormal pressure on the plantar metatarsal heads, and relieve pain (5)[C].

PROGNOSIS
Outcome depends on the severity of the problem and whether surgery is required to correct it.

COMPLICATIONS
- Back, knee, and hip pain due to change in gait
- Transfer metatarsalgia following surgical intervention, which subsequently transfers stress to other areas.

REFERENCES

ADDITIONAL READING

SEE ALSO
Morton Neuroma (Interdigital Neuroma)

CODES

ICD10
- M77.40 Metatarsalgia, unspecified foot
- G57.60 Lesion of plantar nerve, unspecified lower limb
- M77.42 Metatarsalgia, left foot

CLINICAL PEARLS

- Metatarsalgia refers to pain of the plantar surface of the forefoot in the region of the metatarsal heads.
- Metatarsalgia is common in athletes who participate in high-impact sports involving the lower extremities.
- Patients describe as “walking with a pebble in the shoe.” Pain is worse during midstance or propulsion phases of walking or running. The most common physical finding is point tenderness over the plantar metatarsal heads.
- Typical treatment is conservative, including rest and ice, activity modification, and ensuring proper padding under the foot.
- Pregnant patients should wear properly fitted, low-heeled shoes to reduce incidence of metatarsalgia.
BASICS

DESCRIPTION
- Community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA) has unique properties that allow the organism to cause skin and soft tissue infections (SSTIs) in healthy hosts:
  - CA-MRSA has a different virulence and disease pattern than hospital-acquired MRSA (HA-MRSA).
- CA-MRSA infections impact patients who have not been recently (<1 year) hospitalized or had a medical procedure (e.g., dialysis, surgery, catheters).
- Incidence of CA-MRSA was steadily increasing in the United States before plateauing between 2005 and 2010.
- CA-MRSA typically causes mild to moderate SSTIs (abscesses, furuncles, and carbuncles).
- Severe or invasive CA-MRSA disease is less frequent but can include:
  - Osteomyelitis
  - Sepsis
  - Septic thrombophlebitis
  - Necrotizing fasciitis
  - Necrotizing pneumonia with abscesses
- Although less frequent, HA-MRSA can still cause SSTIs in the community.
- System(s) affected: skin, soft tissue

EPIDEMIOLOGY
- Predominant age: all ages, generally younger
- Predominant sex: female > male

Incidence
- SSTI incidence decreased from 32 to 20 per 1,000 ED encounters between 2009 and 2014.
- 46/100,000 per year pediatric MRSA SSTI hospitalizations.
- The incidence of MRSA-related hospitalizations decreased from 2010 to 2014.
- The incidence of MRSA-related skin abscesses among people who inject drugs is increasing.

Prevalence
- Local epidemiology patterns vary.
- 25–30% of U.S. population colonized with S. aureus; up to 7% are colonized with MRSA.
- CA-MRSA isolated in ~60% of SSTIs presenting to emergency departments (range 15–74%).
- CA-MRSA accounts for up to 75% of all community staphylococcal infections in children.

ETIOLOGY AND PATHOPHYSIOLOGY
- First noted in 1980. Current epidemic began in 1999. The USA300 clone is predominant.
- CA-MRSA is distinguished from HA-MRSA by:
  - Lack of a multidrug-resistant phenotype
– Presence of exotoxin virulence factors
– Type IV Staphylococcus cassette cartridge (contains the methicillin-resistant gene mecA)

RISK FACTORS
~50% of patients have no obvious risk factor. Other risk factors include:
● Antibiotic use in the past month, particularly cephalosporin and fluoroquinolone
● Abscess
● Reported “spider bite”
● Intravenous (IV) drug use
● HIV infection
● Hemodialysis catheter
● History of MRSA infection
● Close contact with a similar infection
● Children, particularly in daycare centers
● Resident in long-term care facility
● Competitive athlete
● Incarceration
● Hospitalization in the past 12 months

GENERAL PREVENTION
● Colonization (particularly of the anterior nares) is a risk factor for subsequent S. aureus infection. Not certain if this is similar for CA-MRSA. Oropharyngeal and inguinal colonization are equally prevalent.
● CA-MRSA transmitted easily through environmental and household contact.
● Health care workers are a primary MRSA vector for hospitalized patients, reinforcing the need for meticulous cleaning of hands and medical equipment.
● Vaccine under development

COMMONLY ASSOCIATED CONDITIONS
Many patients are otherwise healthy.

DIAGNOSIS

HISTORY
● Review risk factors.
“Spider bite” is commonly confused with MRSA—patients often report an unclear history of spider bite.
● Prior MRSA skin infection.
● Risk factors alone cannot rule in or rule out a CA-MRSA infection.

PHYSICAL EXAM
● Furuncles and/or carbuncles, sometimes with surrounding cellulitis. Nonsuppurative cellulitis is a less common presentation of CA-MRSA.
● Erythema, warmth, tenderness, swelling
● Fluctuance
- Folliculitis, pustular lesions
- Appearance can be confused with an insect or spider bite.
- Tissue necrosis

**DIFFERENTIAL DIAGNOSIS**

SSTIs due to other organisms

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Wound cultures establish definitive diagnosis. Guidelines recommend culture of a purulent lesion with systemic signs of illness or if the patient is immunocompromised (1)[B].
- Susceptibility testing; many labs use oxacillin instead of methicillin.
- “D-zone disk-diffusion test” evaluates for inducible clindamycin resistance if CA-MRSA is resistant to erythromycin.
- Ultrasound may help identify abscesses (2),(3)[A].
- Look for fascial plane edema on computed tomography or magnetic resonance imaging if necrotizing fasciitis is suspected. DO NOT DELAY surgical intervention to obtain imaging in such cases.

**Diagnostic Procedures/Other**

Incision and drainage (I&D) purulent lesions; needle aspiration not recommended (1).

**TREATMENT**

- Consider surgical drainage, wound culture, and narrow-spectrum antimicrobials for purulent infections.
- See below in Alert section regarding use of antibiotics in uncomplicated cases.
- Use antibiotics that are active against MRSA for patients with carbuncles or abscesses if patients do not respond to initial antibiotic treatment, have markedly impaired host defenses, or present with systemic inflammatory response syndrome (SIRS) and hypotension (1).
- Packing may not improve outcomes (3)[A].
- Moist heat may work for small furuncles.
- Extended antibiotic coverage for CA-MRSA is not warranted for nonsuppurative cellulitis (4)[A].
- Routine elimination of MRSA colonization is not recommended in patients with active infection or their close contacts.
- Most CA-MRSA infections are localized SSTIs and do not require hospitalization or vancomycin.
- Base initial antibiotic coverage on local CA-MRSA prevalence and individual risk factors.

**GENERAL MEASURES**

- Modify therapy based on culture and susceptibility.
- Determine if household/close contacts have SSTI.
- Treat underlying conditions (e.g., tinea pedis).
- Restrict contact (e.g., sports competition) if wound cannot be covered.
- Elevate affected area.
**MEDICATION**

**ALERT**

Patients with an abscess are frequently cured by I&D alone. The addition of clindamycin or trimethoprim/sulfamethoxazole (TMP/SMX) for abscesses <5 cm results in modestly improved cure rates at 7 to 14 days (number needed to treat is 7 to 14) (5)[A].

**First Line**

Antibiotics for CA-MRSA SSTIs: 7- to 14-day course (depends on severity and clinical response):

- **TMP/SMX**: DS (160 mg TMP and 800 mg of SMX) 1 to 2 tablet(s) PO q12h; children, 8 to 12 mg/kg/day PO of trimethoprim component in 2 divided doses.
- **Doxycycline or minocycline**: 100 mg PO q12h. Children, >8 years and <45 kg, 2 to 5 mg/kg/day PO in 1 to 2 divided doses, not to exceed 200 mg/day; >8 years and >45 kg, use adult dosing; taken with a full glass of water.
- **Clindamycin**: 300 to 450 mg PO q6h. Children, 30 to 40 mg/kg/day PO in 3 divided doses. Taken with full glass of water. Check D-zone test in erythromycin-resistant, clindamycin-susceptible S. aureus isolates (a positive test indicates induced resistance—choose a different antibiotic).
- **CA-MRSA** is resistant to β-lactams (including oral cephalosporins and antistaphylococcal penicillins) and often macrolides, azalides, and quinolones.
- **Although most CA-MRSA isolates are susceptible to rifampin, this drug should never be used as a single agent because of concerns regarding resistance. The role of combination therapy with rifampin in CA-MRSA SSTIs is not clearly defined.**
- **There has been increasing resistance to clindamycin, both initial (~33%) and induced.**
- **Although CA-MRSA isolates are susceptible to vancomycin, oral vancomycin cannot be used for CA-MRSA SSTIs due to limited absorption.**

**Second Line**

Treat severe CA-MRSA SSTIs requiring hospitalization and HA-MRSA SSTIs using:

- **Vancomycin**: Generally, 1 g IV q12h (30 mg/kg/day IV in 2 divided doses). Children: 40 mg/kg/day IV in 4 divided doses. Vancomycin-like antibiotics that require only 1 or 2 doses are also available (6)[A].
- **Linezolid**: 600 mg IV/PO q12h. Children, uncomplicated: <5 years of age, 30 mg/kg/day IV/PO in 3 divided doses; 5 to 11 years of age, 20 mg/kg/day IV/PO in 2 divided doses; >11 years, use adult dosing. Children, complicated: birth to 11 years, 30 mg/kg/day IV/PO in 3 divided doses; older, use adult dosing.
  - Linezolid seems to be more effective than vancomycin for treating people with SSTIs, but current studies have high risk of bias.
- **Clindamycin**: 600 mg IV q8h; children, 10 to 13 mg/kg/dose IV q6–8h up to 40 mg/kg/day.
- **Daptomycin**: 4 mg/kg/day IV; children, 1 to <2 years, 10 mg/kg IV once daily; 2 to 6 years, 9 mg/kg IV once daily; 7 to 11 years, 7 mg/kg IV once daily; 12 to 17 years, 5 mg/kg IV once daily; ≥18 years, adult dosing.
  - Do not use if pulmonary involvement.
- **Ceftaroline**: 600 mg IV q12h; children, 2 months to <2 years, 8 mg/kg IV q8h; ≥2 years to <18 years and ≤33 kg, 12 mg/kg IV q8h; ≥2 years to <18 years and >33 kg, 400 mg IV q8h OR 600 mg IV q12h; ≥18 years, adult dosing.
Pediatric Considerations
- Tetracyclines not recommended for patients age <8 years for CA-MRSA (in contrast with their position as treatment of choice in tickborne rickettsial diseases).
- TMP/SMX not recommended for patients <2 months.
- Daptomycin is not recommended in pediatric patients <1 year of age (risk of potential muscular, neuromuscular, and/or nervous system side effects).
- Daptomycin dosage adjustment for pediatric patients with renal impairment has not been established.
- Ceftaroline dosage adjustment for pediatric patients with CrCl \leq 50 \text{mL/min}/1.73 \text{m}^2 has not been established.

Pregnancy Considerations
- Tetracyclines are contraindicated.
- TMP/SMX not recommended in 1st or 3rd trimester.

Geriatric Considerations
A recent review notes no prospective trials in this age group and recommends use of general adult guidelines.

ISSUES FOR REFERRAL
Consider consultation with infectious disease if:
- Refractory CA-MRSA infection
- Plan to attempt decolonization.

SURGERY/OTHER PROCEDURES
Concern for serious SSTIs (including necrotizing fasciitis) mandates prompt surgical evaluation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Consider admission if:
  - Systemically ill. Extensive soft tissue involvement.
  - Comorbidities that may delay or complicate resolution of SSTI. Immunocompromised status.
  - Failure to improve despite appropriate oral antibiotic therapy
  - Presence of SSTI complications (sepsis, necrotizing fasciitis) and comorbidities.
  - Alternatives to inpatient admission include observation units and outpatient parenteral antimicrobial therapy (OPAT) in carefully selected cases.
- Nursing: contact precautions
- If admitted for IV therapy, assess the following before discharge:
  - Afebrile for 24 hours
  - Clinically improved
  - Able to take oral medication
  - Has adequate social support and is available for outpatient follow-up

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients who present with intravenous drug use should be effectively connected to ongoing
substance use disorder care.

**Patient Monitoring**
For outpatients:
- Promptly return for care with systemic symptoms, worsening local symptoms, or failure to improve within 48 hours. Consider a follow-up within 48 hours of initial visit to assess response and review culture.

**PATIENT EDUCATION**
- Cover draining wounds with clean, dry bandages.
- Clean hands regularly with soap and water or alcohol-based gel; hot soapy shower daily.
- Do not share items that may be contaminated (including razors or towels).
- Clean clothes, towels, and bed linens.
- CDC MRSA Education: [https://www.cdc.gov/mrsa/](https://www.cdc.gov/mrsa/).
- A mixture of 1/4 cup household bleach diluted in 1 gallon of water can be used to clean potentially contaminated surfaces.

**PROGNOSIS**
In outpatients, improvement should occur within 48 hours.

**COMPLICATIONS**
- Necrotizing pneumonia or empyema (after an influenza-like illness)
- Necrotizing fasciitis
- Sepsis syndrome
- Pyomyositis and osteomyelitis
- Purpura fulminans
- Disseminated septic emboli
- Endocarditis

**REFERENCES**

**ADDITIONAL READING**
- Breyre A, Frazee BW. Skin and soft tissue infections in the emergency department. Emerg

**CODES**

**ICD10**

- A49.02 Methicillin resis staph infection, unsp site
- A41.02 Sepsis due to Methicillin resistant Staphylococcus aureus
- J15.212 Pneumonia due to Methicillin resistant Staphylococcus aureus

**CLINICAL PEARLS**

- Incise and drain abscesses and send purulent material for culture and sensitivity.
- Local susceptibility patterns of CA-MRSA should guide empiric antibiotic treatment.
- CA-MRSA skin lesions are commonly misidentified as “spider bites.”
MILD COGNITIVE IMPAIRMENT
Birju B. Patel, MD, FACP • N. Wilson Holland, MD, FACP, AGSF

BASICS

DESCRIPTION

● Mild cognitive impairment (MCI) is defined as significant cognitive impairment in the absence of dementia, as measured by standard memory tests:
  – Concern regarding change in cognition
  – Preservation of independence in functional activities (ADLs)
  – Impairment in ≥1 cognitive domains (attention, executive dysfunction, memory, visuospatial, language)
  – Other terms used in the literature relating to MCI: Cognitive impairment not dementia (CIND); predementia; mild cognitive disorder; age-associated memory impairment; age-related cognitive decline. Some of these conditions do not progress to dementia (i.e., age-associated memory impairment, age-related cognitive decline). Diagnostic and Statistical Manual of Mental Disorders, 5th edition mentions “mild neurocognitive disorder” (mNCD), which may be a precursor to Alzheimer disease and has many of the same features as MCI.

● Older adults with MCI are 3 times more likely to progress to dementia in 2 to 5 years than age-matched cohorts (1)[A].

EPIDEMIOLOGY

Incidence

● Predominant sex: male > female

● Predominant age:
  – Higher in older persons and in those with less education
  – 12 to 15/1,000 person-years in those age ≥65 years
  – 54/1,000 person-years in those age ≥75 years

Prevalence

● MCI is more prevalent than dementia in the United States.

● 12–18% for those age ≥60 years. ~25% for age 80–84 years. Prevalence increases with age and for those with lower educational level (2).

ETIOLOGY AND PATHOPHYSIOLOGY

● Subtypes of MCI:
  – Single-domain amnestic
  – Multiple-domain amnestic
  – Nonamnestic single-domain
  – Nonamnestic multiple-domain

● The amnestic subtype is higher risk for progression to Alzheimer disease.

● Vascular, degenerative, traumatic, metabolic, psychiatric, or a combination

Genetics

Apolipoprotein (APO) E4 genotype: Various pathways exist leading to amyloid accumulation and deposition thought to be associated with dementia.
RISK FACTORS
- Age
- Diabetes
- Hypertension
- Hyperlipidemia
- Cerebrovascular disease
- Smoking
- Sleep apnea
- APO E4 genotype
- Low educational levels

COMMONLY ASSOCIATED CONDITIONS
See “Risk Factors.”

DIAGNOSIS

HISTORY
- Focus on cognitive deficits and impairment. MCI is meant to reflect a change in cognition and not lifelong impaired cognition.
- Review all medications that may affect cognition; give emphasis to anticholinergic medications (patients on these may mistakenly be classified as having MCI).
- Rule out depression. The prevalence of depression in patients with MCI is higher than age-matched cohorts.
- Assess function (ADLs, instrumental ADLs) and subtle changes in daily function (e.g., in the workplace).
- Impact on interpersonal relationships and caregiver stress
- Assess vascular risk factors (hypertension, diabetes, hyperlipidemia, and cerebrovascular disease).
- Assess behavioral changes.
- Olfactory dysfunction may be associated with amnestic MCI and progression to Alzheimer dementia. This can be easily evaluated in patients with memory impairment (3).

PHYSICAL EXAM
- A general exam focusing on clinical clues to identifying vascular disease (e.g., bruits, abnormal blood pressure [BP])
- Neurologic exam to rule out reversible central nervous system (CNS) causes cognitive impairment or other causes of cognitive impairment (e.g., Parkinson disease).
- Office measures of cognitive function, depression, and functional status

DIFFERENTIAL DIAGNOSIS
- Delirium
- Dementia
- Depression
- “Reversible” cognitive impairment
  - Medications (anticholinergics and medications with anticholinergic properties)
  - Hypothyroidism
– Vitamin B\textsubscript{12} deficiency
• Reversible CNS conditions
• Give consideration to sleep conditions, especially sleep apnea, that can contribute to cognitive deficits.

**DIAGNOSTIC TESTS & INTERPRETATION**
• Cognitive testing is important (e.g., Montreal Cognitive Assessment [MoCA] and Saint Louis University Mental Status [SLUMS]); MoCA may be more sensitive for detecting and following MCI.
• Neuropsychological testing is recommended for all patients with confirmed MCI.

**Initial Tests (lab, imaging)**
• Complete blood count
• Comprehensive metabolic profile
• Thyroid-stimulating hormone
• Vitamin B\textsubscript{12}
• Lipids
• Consider HIV testing in the appropriate risk setting.
• Imaging tests are helpful when there are focal neurologic deficits or rapid or atypical presentations:
  – CT scan can detect structural CNS conditions leading to cognitive impairment:
    o Subdural hematoma
    o Normal pressure hydrocephalus
    o Metastatic disease
  – MRI further evaluates vascular, infectious, neoplastic, and inflammatory conditions.
• Vascular risk factor reduction and treatment

**Follow-Up Tests & Special Considerations**
• Document progression of functional impairment, cognitive decline, concurrent depression, and comorbid conditions.
• Advanced planning while patient is competent
• Early education of caregivers on safety, maintaining structure, managing stress, and future planning
• Neuropsychological testing should be done at 1- to 2-year intervals depending on subjective concerns and ongoing diagnosis of MCI.

**Test Interpretation**
• Little is known about MCI pathology due to a lack of longitudinal studies.
• Alzheimer dementia pathophysiology:
  – Neurofibrillary tangles in hippocampus
  – Senile plaques (amyloid deposition)
  – Neuronal degeneration
• Those with MCI have intermediate amounts of pathologic findings of Alzheimer disease with amyloid deposition and neurofibrillary tangles in the mesial temporal lobes compared with those with dementia.
• Amnestic MCI is associated with white matter hyperintensity volume on MRI, whereas nonamnestic MCI is associated with infarcts.
TREATMENT

GENERAL MEASURES
Atherosclerotic risk factors should be treated aggressively.

MEDICATION
The use of cholinesterase inhibitors (ChEIs) in MCI is not associated with any delay in the onset of Alzheimer disease or dementia. Moreover, the safety profile showed that the risks associated with ChEIs are significant. Therefore, ChEIs are not routinely recommended (1)[B]. Clinicians may choose not to offer ChEIs.

ISSUES FOR REFERRAL
Consider referral to a memory specialist (i.e., geriatrician, neurologist, geropsychiatrist, neuropsychologist) to evaluate and differentiate subtypes of MCI and specific cognitive deficits.

ADDITIONAL THERAPIES
There may be benefit in terms of improvement in performance on tests for global cognitive functioning with cognitive training and physical exercise. Exercise training for 6 months is likely to improve cognitive measures.

COMPLEMENTARY & ALTERNATIVE MEDICINE
No evidence suggests the efficacy of vitamin E in the prevention or treatment of people with MCI. More research is needed to identify the role of vitamin E, if any, in the management of cognitive impairment.

- Long-term use of Ginkgo biloba extract has shown to have no benefit in the treatment of MCI and in terms of progression to dementia. In addition, Ginkgo biloba can be associated with increase in bleeding risk including CNS bleeds (4)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Delirium is more common in patients hospitalized with all forms of cognitive impairment.

- Avoid medications that may worsen or precipitate cognitive decline (e.g., anticholinergics, antihistamines).

- Patients may be extremely sensitive to the hospital environment:
  - Moderate level of stimulation is best.
  - Avoid sensory deprivation. Make sure that patients have access to hearing aids and eyeglasses.
  - Use frequent cueing and have caregivers or family in the room whenever possible with patient.
  - Frequently orient patients to date and time.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should be reevaluated every 6 to 12 months to determine if symptoms are progressing.

Patient Monitoring
Appropriate cognitive and functional testing should be used to evaluate progression, along with
clinical history and exam. If a medication is started, patients need to be followed more frequently to evaluate for efficacy, side effects, dose titration, and so forth. Declining executive function may be an early marker to progression of MCI to dementia, and clinicians should monitor and advise patients and families proactively to look for this. Impairments in ADL function is a good clue to progression to dementia from MCI. Attempts should be made to wean medications that can impact cognition.

DIET
Diets that are promoted by the American Heart Association to minimize atherosclerotic risk factors should be emphasized.

PATIENT EDUCATION
- Discuss diagnosis and uncertainties about prognosis.
- Long-term planning topics should be discussed including advanced directives, firearm safety, driving safety, finances, and estate planning.
- Encourage lifestyle changes:
  - Physical activity, such as walking 30 minutes daily on most days of the week, as exercise modestly improved some measures of cognition in some studies.
  - Mental activity that stimulates language skills and psychomotor coordination should be encouraged. Computer activities, reading books, crafts, crossword puzzles, and games may be linked to decreased risk of development of MCI (5)[C].
- Cognitive rehabilitation strategies may be beneficial in helping with daily activities relating to memory tasks in MCI.
- Treatment of vascular risk factors (hypertension, diabetes, cerebrovascular disease, and hyperlipidemia) is important in lowering risk of progression to dementia. Intensive BP lowering in the Sprint Mind Study reduced incidence of MCI with target systolic BP of 120 mm Hg.
- Discuss with patients and families that there are no FDA-approved medications or dietary agents currently shown to have benefit for MCI.

PROGNOSIS
- Older adults with MCI have 3 times higher risk of progression to dementia in 2 to 5 years.
- Amnestic subtypes of MCI are most likely to progress to dementia.
- Neuropsychological testing measures, cerebrospinal fluid (CSF) biomarkers, and neuroimaging studies are being used in specialty settings to predict conversion to dementia. These are not widely available or cost-effective and are not used in general use.

REFERENCES

ADDITIONAL READING

CODES

ICD10

G31.84 Mild cognitive impairment, so stated

CLINICAL PEARLS

- Amnestic MCI affects primarily memory and is more likely to progress to Alzheimer dementia.
- Screen for reversible factors, particularly anticholinergic medications, depression, and sleep disorders.
- Look closely at vascular risk factors and modify them as best as possible.
- ChEIs should not be used routinely unless memory complaints are affecting quality of life in patients. Potential side effects of these medications should be thoroughly discussed with patients and their families. A baseline ECG should be done prior to initiation of ChEIs due to risk of bradycardia and syncope.
- Neuropsychological testing is recommended in individuals suspected of having MCI. Patients with MCI and with prominent subjective complaints should have follow-up testing to evaluate for progression between 1 and 2 years after the initial assessment.
MISCELLANEOUS (EARLY PREGNANCY LOSS)
Clara M. Keegan, MD

BASICS

DESCRIPTION

- Miscarriage, also known as early pregnancy loss (EPL), and formerly as spontaneous abortion (SAb), is the failure or loss of a pregnancy before 13 weeks' gestational age (WGA).
- Related terms:
  - Anembryonic gestation: gestational sac on ultrasound (US) without visible embryo after 6 WGA
  - Complete abortion: entire contents of uterus expelled
  - Ectopic pregnancy: pregnancy outside the uterus
  - Embryonic or fetal demise: cervix closed; embryo or fetus present in the uterus without cardiac activity
  - Incomplete abortion: abortion with retained products of conception, generally placental tissue
  - Induced or therapeutic abortion: evacuation of uterine contents or products of conception medically or surgically
  - Inevitable abortion: cervical dilatation or rupture of membranes in the presence of vaginal bleeding
  - Recurrent abortion: ≥3 consecutive pregnancy losses at <15 WGA
  - Threatened abortion: vaginal bleeding in the 1st trimester of pregnancy
  - Septic abortion: a spontaneous or therapeutic abortion complicated by pelvic infection; common complication of illegally performed induced abortions
- Synonym(s): spontaneous abortion
  - Missed abortion and blighted ovum are used less frequently in favor of terms representing the sonographic diagnosis.

EPIDEMIOLOGY

Predominant age: increases with advancing age, especially >35 years; at age 40 years, the loss rate is twice that of age 20 years.

Incidence

- Threatened abortion (1st-trimester bleeding) occurs in 20–25% of clinical pregnancies.
- Between 10% and 15% of all clinically recognized pregnancies end in EPL, with 80% of these occurring within 12 weeks after last menstrual period (LMP) (1).
- When both clinical and biochemical (β-hCG detected) pregnancies are considered, about 30% of pregnancies end in EPL.
- One in four women will have an EPL during her lifetime (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Chromosomal anomalies (50% of cases)
- Congenital anomalies
- Trauma
- Maternal factors: uterine abnormalities, infection (toxoplasma, other viruses, rubella,
cytomegalovirus, herpesvirus), maternal endocrine disorders, hypercoagulable state

**Genetics**
Approximately 50% of 1st-trimester EPLs have significant chromosomal anomalies, with 50% of these being autosomal trisomies and the remainder being triploidy, tetraploidy, or 45X monosomies.

**RISK FACTORS**
Most cases of EPL occur in patients without identifiable risk factors; however, risk factors include the following:
- Chromosomal abnormalities
- Advancing maternal age
- Uterine abnormalities
- Maternal chronic disease (antiphospholipid antibodies, uncontrolled diabetes mellitus, polycystic ovarian syndrome, obesity, hypertension, thyroid disease, renal disease)
- Other possible contributing factors include smoking, alcohol, cocaine use, infection, and luteal phase defect.

**GENERAL PREVENTION**
- Insufficient evidence supports the use of aspirin and/or other anticoagulants, bed rest, hCG, immunotherapy, progestogens, uterine muscle relaxants, or vitamins for general prevention of EPL, before or after threatened abortion is diagnosed.
- By the time hemorrhage begins, half of pregnancies complicated by threatened abortion already have no fetal cardiac activity.
- Recurrent miscarriage: Women with a history of ≥3 prior EPLs may benefit from progestogens (OR 0.39, 95% CI 0.21–0.72) (2)[A].
- Antiphospholipid syndrome: The combination of unfractionated heparin and aspirin reduces risk of EPL in women with antiphospholipid antibodies and a history of recurrent abortion (3) [C].

**DIAGNOSIS**

**HISTORY**
- The possibility of pregnancy should be considered in a reproductive-age woman who presents with nonmenstrual vaginal bleeding.
- Vaginal bleeding
  - Characteristics (amount, color, consistency, associated symptoms), onset (abrupt or gradual), duration, intensity/quantity, and exacerbating/precipitating factors
  - Document LMP if known: allows calculation of estimated gestational age
- Abdominal pain/uterine cramping, as well as associated nausea/vomiting/syncope
- Rupture of membranes
- Passage of products of conception
- Prenatal course: toxic or infectious exposures, family or personal history of genetic abnormalities, past history of ectopic pregnancy or EPL, endocrine disease, autoimmune disorder, bleeding/clotting disorder

**PHYSICAL EXAM**
• Orthostatic vital signs to estimate hemodynamic stability
• Abdominal exam for tenderness, guarding, rebound, bowel sounds (peritoneal signs more likely with ectopic pregnancy)
• Speculum exam for visual assessment of cervical dilation, blood, and products of conception (confirms diagnosis of EPL)
• Bimanual exam to assess for uterine size–dates discrepancy and adnexal tenderness or mass

DIFFERENTIAL DIAGNOSIS
• Ectopic pregnancy: potentially life-threatening; must be considered in any woman of childbearing age with abdominal pain and vaginal bleeding
• Physiologic bleeding in normal pregnancy (implantation bleeding)
• Subchorionic bleeding
• Cervical polyps, neoplasia, and/or inflammatory conditions
• Hydatidiform mole pregnancy
• hCG-secreting ovarian tumor

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Quantitative hCG
  – Particularly useful if intrauterine pregnancy (IUP) has not been documented by US
  – Serial quantitative serum hCG measurements can assess viability of the pregnancy. Serum hCG should rise at least 53% every 48 hours through 7 weeks after LMP. An inappropriate rise, plateau, or decrease of hCG suggests abnormal IUP or possible ectopic pregnancy.
• Complete blood count (CBC) with differential
• Rh type
• Cultures: gonorrhea/chlamydia
• US exam to evaluate fetal viability and to rule out ectopic pregnancy (4)[A]
  – hCG >2,000 mIU/mL necessary to detect IUP via transvaginal US (TVUS), >5,500 mIU/mL for abdominal US
  – TVUS criteria for nonviable intrauterine gestation: 7-mm fetal pole without cardiac activity or 25-mm gestational sac without a fetal pole, IUP with no growth over 1 week, or previously seen IUP no longer visible
  – Structures and timing: with TVUS, gestational sac of 2 to 3 mm generally seen around 5 WGA; yolk sac by 5.5 WGA; fetal pole with cardiac activity by 6 WGA

Follow-Up Tests & Special Considerations
• In the case of vaginal bleeding with no documented IUP and hCG <2,000 mIU/mL, follow serum hCG levels weekly to zero.
• If levels plateau, consider ectopic pregnancy or retained products of conception. If levels are very high, consider gestational trophoblastic disease.
• If initial hCG level does not permit documentation of IUP by TVUS, follow serum hCG in 48 hours to document appropriate rise.
• Repeat US once hCG is at a level commensurate with visualization on US (see above).
• Provide patient with ectopic precautions in interim: worsening abdominal pain, dizziness/syncope, nausea/vomiting.
• In a pregnancy of unknown location with hCG rise <53% in 48 hours, offer methotrexate for treatment of presumed ectopic pregnancy.
**Diagnostic Procedures/Other**
- Fetal heart tones can be auscultated with Doppler starting between 10 and 12 WGA in a viable pregnancy.
- In threatened abortion, fetal cardiac activity at 7 to 11 WGA is 90–96% predictive of continued pregnancy (1).

**TREATMENT**

**GENERAL MEASURES**
- Discuss contraception plan at the time of diagnosis of EPL, as ovulation can occur prior to resumption of normal menses.
- Expectant management (“watchful waiting”) is 90% effective for incomplete abortion, although it may take several weeks for the process to be complete (1)[A]. This approach is only recommended in the 1st trimester and is more effective in women with symptoms of impending pregnancy loss (3)[C].

**MEDICATION**
- Rates of complete miscarriage and of need for surgical evacuation are equivalent with expectant management and medication (5)[A].
- Long-term conception rate and pregnancy outcomes are similar for women who undergo expectant management, medical treatment, or surgical evacuation.
- Infection rates are lower with medical versus surgical management.

**First Line**
- Misoprostol: most common agent for inducing passage of tissue in incomplete abortion or embryonic demise
  - Off-label use; has not been submitted to the Food and Drug Administration for consideration for use in treatment of early pregnancy failure; recognized by the World Health Organization (WHO) as a life-saving medication for this indication
  - Efficacy: complete expulsion of products of conception in 71% by day 3, 84% by day 8
  - Efficacy depends on route of administration, gestational age of pregnancy, and dose.
  - Recommended dose is 800 μg vaginally; alternate regimens include the WHO regimen of 600 μg sublingually q3h for up to 3 doses; multidose regimens and oral dosing (including buccal and sublingual) may result in increased side effects.
  - The addition of mifepristone 200 mg, if available, given 24 hours before misoprostol increases the efficacy to 83.8% (ARR 16.7%, 95% CI 7.1–26.3%) (6)[A].
- Common adverse effects include abdominal pain/cramping, nausea, and diarrhea. Pain increases at higher doses but is manageable with oral analgesia.
- Recommended for stable patients who decline surgery but do not want to wait for spontaneous passage of products of conception.

**Second Line**
- Rh-negative patients should be given Rh immunoglobulin (RhoGAM) 50 μg IM following an EPL.
- Women with evidence of anemia should receive iron supplementation.

**ISSUES FOR REFERRAL**
Patients should be monitored for up to 1 year for the development of pathologic grief. There is insufficient evidence to support counseling to prevent development of anxiety or depression related to grief following EPL.

SURGERY/OTHER PROCEDURES
- Uterine aspiration (suction dilation and curettage [D&C] or manual uterine aspiration [MUA]), also known as manual vacuum aspiration (MVA), is the conventional treatment.
- Indications: septic abortion, heavy bleeding, hypotension, persistent IUP after medical or expectant management, patient choice
- Risks (all rare): anesthesia (usually local), uterine perforation, intrauterine adhesions, cervical trauma, infection that may lead to infertility or increased risk of ectopic pregnancy
- When compared with expectant management, surgical intervention leads to fewer days of vaginal bleeding, with a lower risk of incomplete abortion and heavy bleeding and a similar risk of infection, but a higher cost (7)[A]. It is appropriate to prioritize the patient’s preference in determining management.
- Vacuum aspiration (manual or electric) is considered preferable to sharp curettage, as aspiration is less painful, takes less time, involves less blood loss, and does not require general anesthesia. The WHO supports use of suction curettage over rigid metal curettage.
- Although data from induced abortions suggest that antibiotic prophylaxis with doxycycline 200 mg in a single dose reduces the already rare risk of postprocedure infection, data are insufficient to support use of antibiotics before aspiration for EPL.

COMPLEMENTARY & ALTERNATIVE MEDICINE
A systematic review of Chinese herbal medicine alone and in conjunction with Western medicine showed benefit over Western medicine alone in achieving continued viability at 28 weeks (number needed to treat [NNT] = 4.8 pregnancies with combined therapy). However, the available studies did not meet international standards for reporting quality.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- If the patient has orthostatic vital signs, initiate resuscitation with IV fluids and/or blood products, if needed.
- Hemodynamically unstable patients may require IV fluids and/or blood products to maintain blood pressure.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
All patients should be offered follow-up in 2 to 6 weeks to monitor for resolution of bleeding, return of menses, and symptoms related to grief, as well as to review the contraception plan.

Patient Monitoring
- If EPL occurs in setting of previously documented IUP and abortion is completed with resumption of normal menses, it is not necessary to check or follow serum hCG to 0.
- After medical management, confirm complete expulsion with US or serial serum β-hCG.
- If pregnancy is not immediately desired, offer effective contraception. Immediate insertion of an intrauterine device is both acceptable and safe.
- If pregnancy is desired, provide preconception counseling. There is no evidence that it is
necessary to wait a certain number of cycles before attempting conception again.

**DIET**

NPO if patient is to undergo D&C under general anesthesia

**PATIENT EDUCATION**

- Pelvic rest for 1 week after D&C or MUA
- Advise patients to call with excessive bleeding (soaking two pads per hour for 2 hours), fever, pelvic pain, or malaise, which could indicate retained products of conception or endometritis.

**PROGNOSIS**

- Prognosis is excellent once bleeding is controlled.
- Recurrent miscarriage: Prognosis depends on etiology; up to 70% rate of success with subsequent pregnancy

**COMPLICATIONS**

- D&C or MUA: uterine perforation, bleeding, adhesions, cervical trauma, and infection that may lead to infertility or increased risk of ectopic pregnancy. Bleeding and adhesions more common with D&C than with MUA; all complications rare
- Retained products of conception

**REFERENCES**

**SEE ALSO**

- Ectopic Pregnancy
- Algorithm: Recurrent Pregnancy Loss
CODES

ICD10

- O03.9 Complete or unspecified spontaneous abortion without complication
- O03.4 Incomplete spontaneous abortion without complication
- O02.1 Missed abortion

CLINICAL PEARLS

- Any pregnant woman with abdominal pain and/or vaginal bleeding must be evaluated to rule out ectopic pregnancy, which is potentially life threatening.
- As all options have similar long-term outcomes, patient preference should determine whether management is expectant, medical, or surgical.
MITRAL REGURGITATION
Yongkasem Vorasettakarnkij, MD, MSc

BASICS

DESCRIPTION
- Disorder of mitral valve (MV) closure, either primary or secondary (functional), resulting in a backflow of the left ventricular (LV) stroke volume into the left atrium (LA); uncompensated, this leads to LV and LA enlargement, elevated pulmonary pressures, atrial fibrillation, heart failure (HF), and sudden cardiac death.
- Types of mitral regurgitation (MR):
  - Acute versus chronic
  - Primary versus secondary (functional)
    - Primary: abnormalities at any level of the MV structures (annulus, leaflets, chordae tendineae, and papillary muscles)
    - Secondary: No valvular abnormalities are found. The abnormal and dilated LV causes papillary muscle displacement, resulting in leaflet tethering with annular dilatation that prevents coaptation.
- System(s) affected: cardiac; pulmonary

EPIDEMIOLOGY
Moderate to severe MR affects 2.5 million people in the United States (2000 data). It is the most common valvular disease and is expected to double by 2030 (1).

Prevalence
- By severity on echocardiography:
  - Mild MR: 19% (up to 40% if trivial jets included)
  - Moderate MR: 1.9%
  - Severe MR: 0.2%
- By category (1)
  - Degenerative (myxomatous disease, annular calcification): 60–70%
  - Ischemic: 20%
  - Endocarditis: 2–5%
  - Rheumatic: 2–5%

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute MR
  - Leaflet perforation: infective endocarditis, trauma
  - Chordae tendineae rupture: trauma, spontaneous rupture, infective endocarditis, or rheumatic fever
  - Papillary muscle rupture or dysfunction: acute myocardial infarction (MI), severe myocardial ischemia, or trauma
- Chronic MR
  - Primary
    - Degenerative: mitral annular calcification, MV prolapse (MVP)
    - Infective endocarditis
Rheumatic heart disease (RHD)

Inflammatory diseases: lupus, eosinophilic endocardial disease

Anorectic drugs

Congenital (cleft leaflet)
  - Secondary (functional)
    - Ischemic: coronary artery disease (CAD)/MI
    - Nonischemic: cardiomyopathy from any cause, annular dilatation from chronic atrial fibrillation, dyssynchrony from right ventricular pacing

- Acute MR: Acute MV damage leads to sudden LA and LV volume overload. Sudden rise in LV volume load without LV remodeling results in impaired forward cardiac output and possible cardiogenic shock.
- Chronic MR: LV eccentric hypertrophy compensates for increased regurgitant volume to maintain forward cardiac output and alleviate pulmonary congestion. However, LV remodeling can result in LV dysfunction. LA compensatory dilatation for the larger regurgitant volume predisposes patients to develop AF.
- Ischemic MR: papillary muscle rupture, ischemia during acute MI, and incomplete coaptation of leaflets or restricted valve movement from chronic ischemia

**RISK FACTORS**
Age, hypertension, RHD, endocarditis, anorectic drugs

**GENERAL PREVENTION**
- Risk factor modification for CAD
- Antibiotic prophylaxis for poststreptococcal RHD
- Endocarditis prophylaxis is no longer recommended.

**COMMONLY ASSOCIATED CONDITIONS**
MVP with MR common in Marfan syndrome

**DIAGNOSIS**

**HISTORY**
- Associated conditions: RHD, prior MI, connective tissue disorder
- Acute MR
  - Sudden onset of dyspnea
  - Orthopnea, paroxysmal nocturnal dyspnea
- Chronic MR
  - Exertional dyspnea, fatigue
  - Palpitation: paroxysmal/persistent AF

**PHYSICAL EXAM**
- Acute MR
  - Rapid and thready pulses
  - Signs of poor tissue perfusion with peripheral vasoconstriction
  - Hyperdynamic precordium without apical shift
  - S₃ and S₄ (if in sinus rhythm)
  - Systolic murmur at left sternal border and base
Early, middle, or holosystolic murmur
- Often soft, low-pitched decrescendo murmur
- Rales

**Chronic MR**
- Brisk upstroke of arterial pulse
- Leftward displaced LV apical impulse
- Systolic thrill at the apex (suggests severe MR)
- Soft S₁ and widely split S₂, S₃ gallop
- Loud P₂ (if pulmonary hypertension)
- Holosystolic murmur at apex that radiates to axilla or to left parasternal boarder
- Ankle edema, jugular venous distension, and ascites, if development of right-sided HF

**DIFFERENTIAL DIAGNOSIS**
- Aortic stenosis (AS): usually midsystolic but can be long; difficult to distinguish from holosystolic, at apical area, and radiating to the carotid arteries (unlike MR)
- Tricuspid regurgitation: holosystolic but at left lower sternal border, does not radiate to axilla, and may increase in intensity with inspiration (unlike MR)
- Ventricular septal defect (VSD): harsh holosystolic murmur at lower left sternal border but radiates to right sternal border (not axilla)

**DIAGNOSTIC TESTS & INTERPRETATION**
- Chest x-ray (CXR)
  - Acute MR: pulmonary edema, normal heart size
  - Chronic MR: LA and LV enlargement
- ECG
  - Acute MR: varies depending on etiologies (e.g., AMI)
  - Chronic MR
    - P mitrale from LA enlargement, AF
    - LV hypertrophy
    - Q waves from prior MI

**Initial Tests (lab, imaging)**
- Cardiac enzymes brain natriuretic peptide, if appropriate
- Transthoracic echocardiogram (TTE)
  - Indications for TTE (2)
    - Baseline evaluation of LV size and function, right ventricular function and LA size, pulmonary artery pressure, and severity of MR
    - Delineation of mechanism of MR
    - Surveillance of asymptomatic moderate to severe LV dysfunction (ejection fraction [EF] and end-systolic dimension [ESD])
    - Evaluate MV apparatus and LV size and function after a change in sign/symptom in MR patient.
    - Evaluate after MV repair or replacement.
  - Findings in acute MR
    - Evidence of etiology: flail leaflet or vegetations
    - Normal LA and LV size
  - Findings in chronic MR
Evidence of degenerative, rheumatic, ischemic, congenital, and other causes

Enlarged LA and LV

**Follow-Up Tests & Special Considerations**

- Intervals for follow-up TTE: See “Follow-Up Recommendations.”
- Cardiovascular magnetic resonance (CMR):
  - TTE results are not satisfactory to assess LV and RV volumes, function, or MR severity (2) B.
- Transesophageal echocardiogram (TEE)
  - Intraoperatively to define the anatomic basis of MR and to guide repair (2)[B]
  - Nondiagnostic information about severity, mechanism of MR, and/or status of LV function from noninvasive imaging (2)[C]
- Exercise hemodynamics with either Doppler echocardiography or cardiac catheterization (2) [B].
  - Discrepancy between symptoms and the severity of MR from resting TTE in symptomatic patients with chronic primary MR
- Exercise treadmill testing (2)[C]
  - To establish symptom status and exercise tolerance in asymptomatic patients with chronic primary MR
- Noninvasive imaging (stress nuclear/position emission tomography, CMR, stress echocardiography, cardiac CT angiography)
  - To establish etiology of chronic secondary MR and/or to assess myocardial viability (2)[C]

**Diagnostic Procedures/Other**

Cardiac catheterization (2)[C]

- Left ventriculography and hemodynamic measurement
  - Noninvasive tests are inconclusive regarding severity of MR, LV function, and the need for surgery.
- Coronary angiography: prior to MV surgery in patients at risk for CAD

**Test Interpretation**

Quantification of severe MR requires integration of the following structural parameters:

- LA size: dilated, unless acute
- LV size: dilated, unless acute
- Leaflets: abnormal
- Doppler parameters
- Quantitative parameter

---

**TREATMENT**

**MEDICATION**

- Acute, severe MR
  - Medical therapy has a limited role and is aimed to stabilize hemodynamics preoperatively.
  - Vasodilators (nitroprusside, nicardipine): to improve hemodynamic compensation but is often limited by systemic hypotension (2,3)[C]
- Chronic MR
– Primary
  o Asymptomatic: no proven long-term medical therapy
  o Symptomatic: diuretics, β-blockers, angiotensin-converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARBs), and possibly aldosterone antagonists as indicated in standard therapy for HF (2)[B],(3)[C]

– Secondary: LV dysfunction or symptomatic (stages B to D)
  o ACE-I or ARBs, β-blockers, and/or aldosterone antagonists as indicated in standard therapy for HF (2)[B],(3)[C]

**SURGERY/OTHER PROCEDURES**

- Isolated MV surgery is not indicated for patients with mild to moderate MR.

- Acute, severe MR secondary to acute MI
  - Acute rupture of papillary muscle: emergency MV repair/replacement
  - Papillary muscle displacement
    o Aggressive medical stabilization and intra-aortic balloon pump
    o Valve surgery usually required in addition to revascularization

- Chronic severe MR
  - Severe primary MR (2,3,4)
    o MV surgery
      ■ Symptomatic patients (stage D)
        □ Absence of severe LV dysfunction (EF >30%) (2,3)[B]
        □ May be considered if presence of severe LV dysfunction (EF ≤30%) (2,3)[C]
      ■ Asymptomatic patients
        □ Mild/moderate LV dysfunction (EF 30–60% and/or ESD ≥40 mm, stage C2) (2)[B]
        □ MV repair is reasonable for asymptomatic patients (stage C1) with preserved LV function (EF >60% and ESD <40 mm):
          ■ The likelihood of a successful and durable repair without residual MR is >95% and expected mortality <1% when performed at a heart valve center of excellence (2)[B].
          ■ Progressive increase in LV size or decrease in EF on serial imaging studies (4)[B]
          ■ Nonrheumatic MR with new onset of AF or resting pulmonary hypertension (pulmonary artery systolic pressure >50 mm Hg) and the likelihood of a successful and durable repair is high (2,3)[B].

- MV repair is recommended over MV replacement in patients with
  - MR limited to the posterior leaflet (2)[B]
  - MR involving the anterior leaflet or both leaflets when a successful and durable repair can be accomplished (2)[B]

- Transcatheter MV repair:
  ■ May be considered for severely symptomatic patients (NYHA class III/IV) despite optimal GDMT for HF, who have a favorable anatomy for the repair, and a reasonable life expectancy but a prohibitive surgical risk from severe comorbidities (2)[B]

- Severe secondary MR (2,3,4)
  - MV surgery
    ■ Undergoing coronary artery bypass graft (CABG) (2,3)[C]
    ■ Undergoing aortic valve replacement (2)[C]
    ■ May be considered for severely symptomatic patients (NYHA classes III and IV) despite optimal GDMT for HF (2)[B],(3)[C]
Chordal-sparing MVR is preferred over downsized annuloplasty repair in ischemic MR patients (4)[B].

- Cardiac resynchronization therapy is recommended for symptomatic patients (stages B to D) who meet the indications for device therapy (2)[C].

Geriatric Considerations
- Medical therapy alone for patients >75 years of age with MR is preferred, owing to increased operative mortality and decreased survival (compared with those with AS), especially with preexisting CAD or need for MV replacement.
- MV repair is preferable than MV replacement.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Acute MR: Stabilize airway, breathing, circulation (ABCs). Initiate IV, O₂, and monitoring. Nitroprusside (plus dobutamine and/or aortic balloon counterpulsation if hypotensive). Treat underlying causes (e.g., MI). Treat acute pulmonary edema with furosemide and morphine. Obtain urgent surgical consultation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Chronic MR: asymptomatic
- Mild MR with normal LV size and function and no pulmonary hypertension: annual clinical evaluation and TTE every 3 to 5 years
- Moderate MR: annual clinical evaluation and TTE every 1 to 2 years
- Severe MR: clinical evaluation, TTE every 6 to 12 months
- Consider serial CXRs and ECGs, and consider stress test if exercise capacity is doubtful.

PATIENT EDUCATION
- Exercise after MV repair: Avoid sports with risk for bodily contact or trauma. Low-intensity competitive sports are allowed.
- Competitive athletes with MR
  - Asymptomatic with normal LV size and function, normal pulmonary artery pressures, and sinus rhythm: no restrictions
  - Mildly symptomatic and those with LV dilatation: activities with low to moderate dynamic and static cardiac demand allowed
- AF and anticoagulation: no contact sports

PROGNOSIS
- Acute, severe MR: Mortality risk with surgery is 50%; mortality risk with medical therapy alone is 75% in first 24 hours and 95% at 2 weeks.
- Chronic MR: asymptomatic severe MR with normal LVEF: 10% yearly rate of progression to symptoms and subnormal resting LVEF. Symptomatic severe MR: 8-year survival rate, 33% without surgery; mortality rate, 5% yearly

Pregnancy Considerations
MR with NYHA functional classes III and IV at high risk for maternal and/or fetal risk
COMPLICATIONS
Acute pulmonary edema, CHF, AF, bleeding risk with anticoagulation, endocarditis, sudden cardiac death

REFERENCES

ADDITIONAL READING

CODES
ICD10
- I34.0 Nonrheumatic mitral (valve) insufficiency
- I05.1 Rheumatic mitral insufficiency
- Q23.3 Congenital mitral insufficiency

CLINICAL PEARLS
- Follow-up for mild to moderate MR: serial exam and/or echo (mild, every 3 to 5 years, moderate 1 to 2 years) unless LV structural changes
- Severe MR is usually managed with MV repair.
- Endocarditis prophylaxis is not recommended.
MITRAL STENOSIS
Gene Pershwitz, MD • Harish C. Devineni, MD

BASICS
DESCRIPTION
- The mitral apparatus is made up of the apparatus, anterior and posterior leaflets which are attached to the anterolateral and posteromedial papillary muscles via the chordae.
- Mitral stenosis (MS) is the narrowing of the valve area causing obstruction of the left ventricular inflow, resulting in increased left atrial pressures and consequent elevation of pulmonary venous and atrial pressures.
- Normal valve orifice 4 to 5 cm²; symptoms typically seen when orifice is <2.5 cm² (1)
- Staging of the disease is used to guide appropriate treatment regimen. Stages vary from A (with risk factors), B (hemodynamically obstruction), C (severe but no symptoms), to D (symptomatic) (1).
- The most common etiology for MS is rheumatic heart disease (RHD), and MS is the most common valvular disease secondary to RHD.
- Other etiologies will be discussed below.

EPIDEMIOLOGY
- Globally, the prevalence of RHD is 30 million. Approximately 470,000 new cases are reported and 233,000 deaths are attributed to RHD yearly (2).
- Predominant age: Symptoms primarily occur in 3rd to 4th decades. Predominant sex: female > male (3:1)

Incidence
Incidence of rheumatic disease in the continental United States remains low. Annual incidence of acute rheumatic fever in the continental United States is unknown, because it is no longer nationally reportable, but is higher in Hawaii and American Samoa. Global burden remains significant (3).

ETIOLOGY AND PATHOPHYSIOLOGY
- Narrowing of the valve orifice leads to obstruction of blood flow between LA and LV. This impairs LV filling during diastole and causes increased LA pressure.
- Increased LA pressure is transmitted passively (“back pressure”) to the pulmonary circulation causing pulmonary hypertension (HTN) and pulmonary congestion over time.
- Chronic LA pressure overload results in atrial dilation and fibrosis, resulting in atrial fibrillation.
- Rheumatic fever: most common (see “Risk Factors”)
- Pathognomonic commissural fusion, leaflet thickening, and “fish mouth appearance” seen with RHD
- Aging (extension of mitral annular calcification)
- Rare causes: congenital (associated with mucopolysaccharidoses), autoimmune: systemic lupus erythematosus (SLE), rheumatoid arthritis, malignant carcinoid, Whipple disease, methysergide therapy, and other acquired: LA myxoma, LA thrombus, endomyocardial fibrosis
RISK FACTORS
- Rheumatic fever is the greatest risk factor.
  - 30–40% of rheumatic fever patients eventually develop MS, presenting 20 years after diagnosis of rheumatic fever.
  - Acute rheumatic fever occurs 2 to 3 weeks after an episode of untreated pharyngitis caused by rheumatogenic group A streptococci (GAS) organism in a genetically susceptible host.
  - Recurrent infections can accelerate the progression of the disease.
  - Low socioeconomic status (i.e., crowded conditions) favors the spread of streptococcal infection.
- Aging (increasing valvular calcification)
- Chest irradiation (increasing tissue fibrosis)

GENERAL PREVENTION
- Prompt recognition and treatment of GAS infection in at-risk populations; recognition of cardinal signs and symptoms of acute rheumatic fever via Jones criteria
- Ultrasound-based screening has been shown to increase diagnosis of RHD in asymptomatic patients residing in areas of high prevalence.

COMMONLY ASSOCIATED CONDITIONS
- Atrial fibrillation (30–40% of symptomatic patients)
- Associated valve lesions due to chronic inflammation (aortic stenosis, aortic insufficiency)
- Pulmonary HTN and right heart failure
- Systemic embolism, stroke, pulmonary embolism (10%)
- Infection, including infectious endocarditis (1–5%)
- Chronic rheumatic myocarditis

DIAGNOSIS
HISTORY
- History of rheumatic fever
- Severity depends on valve area; most early cases will be asymptomatic.
- Mean age of symptom onset in rheumatic valvular disease is in the late 30s to 40s. Latent period 20 to 40 years after infection. Rapid progression can be seen in some high prevalence areas.
- Presenting features usually include dyspnea on exertion, decrease exercise tolerance, chest pain, embolic events, palpitations, hoarseness, hemoptyisis, fatigue, paroxysmal nocturnal dyspnea, atrial fibrillation, and embolic events.
- In advanced disease, symptoms of pulmonary HTN and right heart failure predominate: jugular venous distention, hepatomegaly, ascites, and peripheral edema.
- Other presentations: hemoptyisis (due to pulmonary vein rupture and bronchial circulation causing intraparenchymal hemorrhage), hoarseness (compression of recurrent laryngeal nerve by enlarged pulmonary artery or LA, Ortner syndrome), dysphagia (compression of bronchi), chronic cough (due to LA compressing the bronchi), and infective endocarditis
- Not infrequently, symptoms are first noted in pregnancy: mitral faces, plethoric cheeks, and bluish patches.
PHYSICAL EXAM
- Elevated jugular venous pressure, left parasternal heave; apical impulse may be displaced, diastolic thrill in the left lateral decubitus position.
- Auscultation
  - Classic murmur: accentuated S\textsubscript{1}, opening snap, apical early decrescendo diastolic rumble with presystolic accentuation (presystolic accentuation of murmur is lost with atrial fibrillation). Murmur is low pitch and best heard at the apex in the left lateral decubitus position.
  - Murmur is accentuated with exercise and decreased with rest and Valsalva.
    - With mobile, noncalcified valve, murmur persists throughout diastole and S\textsubscript{1}, and the opening snap remains loud.
    - With increasing severity of MS, murmur often is difficult to hear. Duration of murmur reflective of severity. S\textsubscript{1} and the opening snap may be soft to absent.
    - A shorter S\textsubscript{2} to O\textsubscript{2} interval indicates more severe MS.
  - Further evaluation is required while looking for concomitant murmurs.
- If pulmonary HTN is present: Increased P\textsubscript{2}, high-pitched decrescendo diastolic murmur of pulmonic insufficiency is heard (Graham Steell murmur); may have signs of right heart failure. RV lift can also be seen.
- May also find associated aortic or tricuspid murmurs due to involvement from RHD

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- ECG (4,5)[C]
  - LA enlargement (manifested by broad, notched P waves in lead II [P mitrale], with P wave duration >0.12 seconds with a negative terminal deflection of the P wave in lead V\textsubscript{1})
  - Atrial fibrillation is a common finding.
  - Right ventricular hypertrophy (RVH), right axis deviation, and an R to S ratio >1 in V\textsubscript{1} are possible.
- Chest radiograph (4,5)[C]
  - LA enlargement, straightening of the left heart border, a “double density,” in the cardiac silhouette, and elevation of the left main stem bronchus
  - Prominent pulmonary arteries at the hilum with rapid tapering, RVH, and edema pattern with Kerley A and B lines (late presentation)
- Transthoracic echo (TTE) recommended in all patients with signs of symptoms of MS (1)[B], (5)[C]
  - Used for diagnosis of MS
    - Assess doming of the valve, mitral orifice size, and commissural fusion.
    - Extent of involvement based on degree of commissural fusion, calcification, and subvalvular fibrosis
    - Hockey stick, fish mouth appearance, which is due to narrowing of the valve orifice
  - Assess for concomitant valvulopathies.
- TEE should be performed if TTE images are nondiagnostic or if being considered for a percutaneous mitral balloon commissurotomy (PMBC) to exclude thrombus in LA and evaluate severity of MR (1)[B].
- Exercise stress testing can also be considered in patients with MS who have a discrepancy in
their symptoms and signs and resting echo findings (1)[C].
- Cardiac catheterization indications (1,5)[C]
- Using Gorlin formula; pressures obtained via transseptal puncture
  - Class I recommendations
    - When echo is inconclusive
  - Class II recommendations
    - Discrepancy between echo, symptoms, and severity
  - Class III recommendations: satisfactory result of echo
  - CT ordered prior to surgery as many at risk for CAD

Follow-Up Tests & Special Considerations
- If valve area $>1.5 \text{ cm}^2$ and mean pressure gradient $<5 \text{ mm Hg}$, clinical follow-up in 3 to 5 years is recommended.
- Otherwise, follow-up is usually symptom based. Symptomatic patients with severe MS need further evaluation for interventional/surgical treatment.
- Holter monitor placement in order to rule out paroxysmal atrial fibrillation

Diagnostic Procedures/Other
- Exercise testing is recommended for those with clinical discrepancy.
- Wilkins score evaluates valvular anatomy from a TTE in order to see if patient is a candidate for surgery.

Test Interpretation
- Rheumatic fever–induced pathologic changes: leaflet thickening, leaflet calcification, commissural fusion, chordal shortening
- MV area defined (1)
  - Normal: 4 to 6 $\text{cm}^2$, progressive MS: $>1.5 \text{ cm}^2$, severe MS: $<1.5 \text{ cm}^2$, very severe: $<1.0 \text{ cm}^2$

TREATMENT

GENERAL MEASURES
- Treatment is dependent on severity of stenosis and symptoms.
- Patients who have a valvular area $>1.5 \text{ cm}^2$ and no symptoms can be managed medically
- MS is generally progressive, and medical therapy only delays the need for definitive therapy. It entails (i) treatment to prevent recurrence of rheumatic fever, (ii) treatments aimed at improving dyspnea and exercise tolerance, (iii) controlling the ventricular rate whether in sinus rhythm or atrial fibrillation, and (iv) anticoagulation for prevention of thromboembolic events.

MEDICATION

First Line
- Antibiotic prophylaxis against rheumatic fever and/or carditis is recommended for patients with history of rheumatic fever (1)[C]. Secondary prophylaxis is dependent on many factors: number of previous attacks, time since previous infection, risk for getting GAS, age of patient, and absence or presence of cardiac involvement.
Antibiotic prophylaxis against infective endocarditis is not routinely recommended, unless there are other indications (1)[B].

Diuretics for congestive symptoms (1)[A]

β-Blockers or nondihydropyridine calcium channel blockers used for controlling heart rate both in sinus rhythm and atrial fibrillation to allow adequate diastolic filling and decrease LA diastolic pressure tachycardia or exertional symptoms (class IIa) (1)

Ivabradine helpful because it doesn’t affect myocardial contraction

Consider cardioversion, especially in patients with mild MS and recent diagnosis of atrial fibrillation (<6 months).

Use of anticoagulation (1)[B]
- Class I recommendations
  - MS and atrial fibrillation or history of atrial fibrillation, MS, and prior embolic event or MS and LA thrombus
- Class IIB recommendations
  - Patients with enlarged LA and spontaneous contrast on echo

Warfarin is the only accepted modality for anticoagulation in patients with rheumatic mitral valve disease (international normalized ratio range 2 to 3).

Heparin in the acute atrial fibrillation setting

The new oral anticoagulants (factor Xa inhibitor and direct thrombin inhibitor) are not approved for use in atrial fibrillation that is secondary to MS.

**Second Line**
One can also consider amiodarone or digitalis if β-blockers and CCBs are not proven beneficial (2)[C].

**SURGERY/OTHER PROCEDURES**
- Surgical techniques include balloon valvotomy, open mitral commissurotomy, or closed mitral commissurotomy and mitral valve replacement.
- Patients with severe MS and symptoms consistent with NYHA classes III and IV are candidates for surgery.
- Any patient with a valve area >1.5 cm$^2$, LA thrombus, moderate MR, severe bicommissural calcifications, severe aortic valve disease, moderate TR or TS, and concomitant coronary artery disease are not candidates for PMBC.
- PMBC is recommended for those with severe MS symptoms and favorable valve morphology (1)[A], in asymptomatic patient with very severe MS and favorable valve anatomy in the absence of symptoms(1)[C], in patients with suboptimal valvular anatomy, with a high risk for surgery (1)[C].
- Balloon valvotomy: symptomatic patients with NYHA class II, III, or IV symptoms with valves that look favorable and with favorable comorbidities (1)[A]
- MV surgery: when MS is severe with severe symptoms (NYHA classes III and IV), who are not high-risk surgical candidates, and balloon valvotomy is contraindicated or failed PMBC (1)[B]; patients with MS requiring left atrial appendage excision
- Patient’s age, bleeding risk, and other comorbidities prior to deciding if patient should have a prosthetic versus mechanical valve

**Pregnancy Considerations**
- Volume expansion during pregnancy can exacerbate heart failure symptoms. Patients with
known severe MS, prepregnancy discussions should be pursued with a cardiologist.

- Pregnant patients can safely use β-blockers. Despite some concerns of teratogenic affects with diuretics, furosemide has been used in symptomatic MS patients during pregnancy with minimal adverse effects.
- Coumadin is considered relatively safe in the 2nd and 3rd trimesters if anticoagulation is required. However, unfractionated heparin is preferred prior to labor and delivery.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Counsel patients that MS usually is slowly progressive but can have sudden onset of atrial fibrillation, which could become rapidly fatal. Call 911 for marked worsening of symptoms.
- Echocardiographic surveillance in asymptomatic patients in any degree of MS: very severe (<1.0 cm²) MS: yearly, severe (≤1.5 cm²) MS: every 1 to 2 years, mild or moderate MS: every 3 to 5 years
- Follow-up will depend on the severity of the MS and the patient’s symptoms.
  - Asymptomatic patients: annual history and examination
  - Symptomatic patients are followed closely based on clinical response to adjust therapy and plan definitive treatment (1)C.

**DIET**

Salt restriction for pulmonary congestion

**PROGNOSIS**

Natural history

- Asymptomatic latent period after rheumatic fever for 10 to 30 years. 10-year survival for asymptomatic or minimally symptomatic patients is 80%.
- 10-year survival after onset of debilitating symptoms is only 0–15%.
- Mean survival with significant pulmonary HTN is <3 years.
- Commissurotomy is an effective means of reducing stenosis but is not curative. Restenosis sometimes occurs and can be early (<5 years) or late (>20 years).

**COMPLICATIONS**

- Left and right heart failure, atrial fibrillation and systemic embolization, pulmonary HTN, pulmonary vasoconstriction hepatic congestion, and bacterial endocarditis
- Pulmonary pressures >50 mm Hg increase surgical risk.

**REFERENCES**

**CODES**

**ICD10**
- I05.0 Rheumatic mitral stenosis
- I05.8 Other rheumatic mitral valve diseases
- I34.2 Nonrheumatic mitral (valve) stenosis

**CLINICAL PEARLS**

- Asymptomatic patients may be followed clinically with yearly exams for development of symptoms with periodic echo to evaluate valve area.
- Once symptoms of MS develop, initiate appropriate medical therapy, but advise patient that, for most, surgical therapy will be needed to prolong survival. Almost all cases of MV stenosis progress in severity over time.
- MS often presents during the intrapartum period. For patients with known severe MS, intervention should be pursued prior to pregnancy. Pregnancy in a patient with severe MS has a high rate of both maternal and fetal complications, including death.
MITRAL VALVE PROLAPSE
Praneeth Katrapati, MD • Brandon D. Coons, MD • Prashanth S. Katrapati, MD, FACC

BASICS
DESCRIPTION
- Mitral valve prolapse (MVP) is a systolic billowing of one or both mitral leaflets into the left atrium (LA) during systole ± mitral regurgitation (MR).
- More specifically, MVP is a single or bileaflet prolapse of at least 2 mm superior displacement into the LA during systole on the parasternal long-axis annular plane of the valve on echocardiogram ± leaflet thickening.
- Classic: prolapse with >5 mm of leaflet thickening
- Nonclassic: prolapse with <5 mm of leaflet thickening
- Synonym(s): systolic click-murmur syndrome; billowing mitral cusp syndrome; myxomatous mitral valve; floppy valve syndrome; redundant cusp syndrome; Barlow syndrome

EPIDEMIOLOGY
Incidence
- Predominant age: MVP has been described in all age groups.
- Initial descriptions based on clinical examinations suggested a 2:1 female predominance.
- Using modern echocardiogram criteria, men and women are affected equally (1).
- The most serious consequences of hemodynamically significant MR occur in patients age >50 years (1).

Prevalence
MVP is the most common valvular abnormality, affecting 2–3% of the general population (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- The pathology causing MVP is multifactorial and includes the following:
  - Abnormal valve tissue
    - Myxomatous degeneration: redundant layers of leaflet “hooding” the cords, chordal elongation, and annular dilatation
    - Myxoid leaflets are more elastic and less stiff than normal valves.
    - Chordal rupture is more common.
  - Disparity in size between the mitral valve and the left ventricle (LV)
  - Connective tissue disorders
- MVP is often associated with variable degrees of MR, which occurs in 9% of patients.
- The degree of MR depends on the degree of leaflet thickening and amount of flail or partially flail segments (2). When this occurs, 10-year mortality is 37% (2).
- Frequently, there is enlargement of the LA and LV.
- Mitral annulus is often dilated.
- Involvement of other valves may occur (tricuspid valve prolapse 40%, pulmonic prolapse and aortic prolapse 2–10%).
- Possible increased vagal tone
Possible increased urine epinephrine and norepinephrine
MVP patients often have orthostatic hypotension and tachycardia.
Genetics causes proliferation of the spongiosa layer of the leaflets and fibrosis on the surface of them (1).
Thinning and elongation of chordae tendineae
The mitral valve differentiates during days 35 to 42 of fetal development, the same time as differentiation of the vertebrae and ribs.

Genetics
Familial MVP is inherited as an autosomal dominant trait but with variable expressivity and incomplete penetrance.
Two genetic loci identified
– MMVP1 on chromosome 16p11.2–p12.1
– MMVP2 on chromosome 11p15.4

RISK FACTORS
MVP is a primary cardiovascular disorder.
MVP is more likely to occur in patients with connective tissue disorders (see “Commonly Associated Conditions”).
Physical characteristics associated with MVP
– Straight thoracic spine
– Pectus excavatum
– Asthenic body habitus
– Low body mass index (BMI)
– Scoliosis or kyphosis
– Hypermobility of the joints
– Arm span > height
– Narrow anteroposterior (AP) diameter of the chest

COMMONLY ASSOCIATED CONDITIONS
Marfan syndrome (91% of Marfan syndrome patients have MVP, although large majority of MVP patients do not meet criteria for Marfan.)
Ehlers-Danlos syndrome
Hypertrophic cardiomyopathy
Pseudoxanthoma elasticum
Osteogenesis imperfecta
von Willebrand disease
Primary hypomastia
Graves disease
Rheumatic heart disease

DIAGNOSIS
Physical exam and echocardiography

HISTORY
Most patients are asymptomatic.
The most frequent symptom is palpitations.

Symptoms related to autonomic dysfunction
- Anxiety and panic attacks
- Arrhythmias
- Exercise intolerance
- Palpitations and chest pains that are atypical for coronary artery disease (CAD)
- Fatigue
- Orthostasis, syncope, or presyncope
- Neuropsychiatric symptoms

Symptoms related to progression of MR
- Fatigue
- Dyspnea
- Exercise intolerance
- Orthopnea
- Paroxysmal nocturnal dyspnea
- Congestive heart failure (CHF)

Symptoms occur as a result of an associated complication (stroke, arrhythmia).

PHYSICAL EXAM

Auscultatory examination
- Mid to late systolic click
  - May vary in timing and intensity based on ventricular beat-to-beat volume variations
  - At low ventricular volumes, the valve may prolapse earlier during systole and further into the LA than during volume overload.
  - It may or may not be followed by a high-pitched, mid to late systolic murmur at the cardiac apex.
- Murmur: a mid to late crescendo systolic murmur best heard at apex, middle to high pitched, occasionally musical or honking in quality
- Occasionally, only the ejection click is present.
- The duration of the murmur corresponds with the severity of MR.

Dynamic auscultation
- Maneuvers that move the click and murmur toward S₁
  - Arterial vasodilation
  - Amyl nitrite
  - Valsalva
  - Augmented contractility
  - Decreased venous return (which can be induced by standing up)
- Maneuvers that move the click and murmur toward S₂
  - Squatting
  - Leg raise
  - Isometric exercise
- Valsalva maneuver may help differentiate hypertrophic obstructive cardiomyopathy (HOCM) from MVP because it increases the intensity of the murmur in HOCM, whereas it makes it longer but not louder in MVP.

DIFFERENTIAL DIAGNOSIS

MR
• Tricuspid regurgitation
• Tricuspid valve prolapse
• Papillary muscle dysfunction
• Hypertrophic cardiomyopathy
• Ejection clicks (do not change timing with systole)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

• **Echocardiogram (test of choice) (3)[B]**
  – In asymptomatic individuals with physical signs of MVP, an echocardiogram is indicated for diagnosis (3)[B].
  – Parasternal long-axis view is most specific for diagnosis (3).
  – Findings that may be seen with MVP
    o Anterior leaflet billowing
    o Leaflet thickening of ≥5 mm
    o Leaflet redundancy
    o MR
    o Posterior leaflet displacement
  – Nondiagnostic transthoracic echocardiogram: ≤10%
  – Transesophageal echocardiography particularly with 3D imaging may be considered to further visualize the anatomy if an intervention is being planned (2)[B].
  – Stress echocardiograms may reveal exercise-induced MR or latent LV dysfunction (3)[B].

• **Angiography**
  – Rarely used for diagnostic purposes
  – Recommended for hemodynamic assessment when noninvasive options or inconclusive (3)[C]

• **ECG is usually normal.**
  – May be nonspecific ST to T wave changes
  – T-wave inversions, prominent Q waves, or prolonged QT may also occur.

• **A chest x-ray (CXR) is not necessary for diagnosis.**
  – Typically, the CXR is normal.
  – Other findings
    o Possible pulmonary edema: Pulmonary edema may be asymmetric with acute chordal rupture and flail leaflet.
    o Possible calcification of the mitral annulus

• **Holter monitoring is optional if patient has palpitations. Order Holter monitoring as usual for syncope or dizziness.**

• **Tilt table testing may be of value in patients with MVP who presents with syncope of unknown etiology (3)[C].**

**Follow-Up Tests & Special Considerations**

• **Periodic monitoring with TTE is recommended in asymptomatic patients with known VHD at intervals depending on valve lesion, severity, ventricular size, and ventricular function (3)[C].**

• **Patients with a family history of MVP should be screened with echocardiography (3)[B].**

**Test Interpretation**

• Myxomatous proliferation of the middle layer (spongiosa) of the valve, resulting in increased
mucopolysaccharide deposition and myxomatous degeneration

- By electron microscopy, the collagen fibers in the valve leaflets are disorganized and fragmented.
- With increased stroma deposition, the valve leaflets enlarge and become redundant.
- The endothelium is usually noncontiguous and a frequent site for thrombus or infective vegetation.

**TREATMENT**

**GENERAL MEASURES**

Treat MVP with orthostatic symptoms by liberalizing fluid and salt intake. If severe, mineralocorticoids may rarely be used. Support stockings may also be beneficial; in the absence of MR, no definitive treatment for MVP (2).

**MEDICATION**

- Asymptomatic MVP is treated with reassurance; normal lifestyle and regular exercise is encouraged.
- MVP with palpitations is treated with β-blockers and/or recommendation to discontinue alcohol, cigarettes, and caffeine.
- MVP and transient ischemic attacks are treated with aspirin 75 to 325 mg daily (3)[C].
- MVP with history of cryptogenic stroke or atrial fibrillation with CHADS2 (acronym for Congestive heart failure, Hypertension, Age >75 years, Diabetes mellitus, and prior Stroke or transient ischemic attack) score <2 is generally treated with aspirin 75 to 325 mg daily (3)[C].
- MVP with atrial fibrillation with CHADS2 score ≥2 is treated with warfarin (3)[C].
- MVP with high-risk echocardiographic features (thickening >5 mm or valve redundancy) and a history of stroke; warfarin therapy may be considered (3)[C].

**ADDITIONAL THERAPIES**

- Endocarditis prophylaxis is no longer recommended for patients with MVP.
- Patients with prior endocarditis undergoing dental, respiratory tract, infected skin, or musculoskeletal procedures should receive prophylaxis for endocarditis with amoxicillin 30 to 60 minutes prior to procedure. Ampicillin, cefazolin, or ceftriaxone IM or IV may be used if unable to tolerate oral medications (3)[B].

**SURGERY/OTHER PROCEDURES**

- Referral for surgery is recommended based on severity of symptoms for patients with severe MR or impaired LV systolic function or flail leaflet owing to ruptured chordae tendineae (3)[B].
- One recent meta-analysis of observational studies suggests a benefit for an early surgical approach to MVP with severe MR (4)[A] even for asymptomatic patients; prospective studies are lacking.
- Minimally invasive mitral valve repair currently being used for high-risk patients; did not reduce MR as much as surgery but similar clinical outcomes (2)[C]
- Surgical repair of MR due to isolated posterior leaflet prolapse is associated with a low reoperation rate (5)[A].
- Asymptomatic patients with atrial fibrillation or pulmonary hypertension should be considered
for intervention as well (3)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years (3)[C].
- Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year (3)[C].
- Patients with MVP and severe MR may require coronary angiography and transesophageal echocardiography if cardiac surgical referral is planned (3)[C].

**PATIENT EDUCATION**
- No contraindication to pregnancy
- Restriction from competitive sports if patient has MVP with one of the following features:
  - A history of syncope associated with documented arrhythmia
  - A family history of MVP-related sudden cardiac death
  - Sustained or repetitive and nonsustained supraventricular tachycardia or frequent and/or complex ventricular tachyarrhythmias on ambulatory Holter monitoring
  - Severe MR
  - A prior embolic event
  - LV systolic dysfunction
- Explain the hereditary nature of familial MVP.

**PROGNOSIS**
- Excellent prognosis for asymptomatic patients
- For patients with severe MR or reduced ejection fraction, the prognosis is similar to that for nonischemic MR.

**COMPLICATIONS**
- Sudden cardiac death: not clearly established; may be secondary to ventricular arrhythmias especially if significant MR is present
- Chordae rupture with acute mitral insufficiency (higher risk of cardiac death; up to 2% per year)
- Infectious endocarditis (risk increased if murmur present)
- Cerebrovascular ischemic event
- Fibrin emboli
- Heart failure with progressive MR
- Arrhythmias such as atrial and ventricular premature beats, paroxysmal supraventricular tachycardias may all be seen. Risk increases with coexistent MR.
- Pulmonary hypertension

ADDITIONAL READING

CODES

ICD10

I34.1 Nonrheumatic mitral (valve) prolapse

CLINICAL PEARLS

- MVP patients may have orthostatic hypotension and tachycardia.
- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years. Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year.
- Consider an early surgical approach for MVP with severe MR.
- Endocarditis prophylaxis is no longer recommended for MVP.
MOLLUSCUM CONTAGIOSUM
Dawn M. Davis, MD, MPH

BASICS

DESCRIPTION
Molluscum contagiosum is a common, benign, viral (poxvirus) skin infection, characterized by small (2 to 5 mm), waxy white or flesh-colored, dome-shaped papules often with central umbilication. Lesions contain a cheesy grayish white material. Molluscum contagiosum is highly contagious and spreads by autoinoculation, skin-to-skin contact, sexual contact, and shared clothing/towels. Molluscum contagiosum is a self-limited infection in immunocompetent patients but can be difficult to treat and disfiguring in immunocompromised patients.

EPIDEMIOLOGY

Prevalence
- 1% in the United States, occurring mainly in children 2 to 15 years and sexually active young adults
- 5–18% HIV population

ETIOLOGY AND PATHOPHYSIOLOGY

- DNA virus; Poxviridae family
- Four genetic virus types, clinically indistinguishable
- Virions invade and replicate in cytoplasm of epithelial cells causing abnormal cell proliferation.
- Genome encodes proteins to evade host immune system.
- Incubation period: 2 to 6 weeks
- Time to resolution: 6 to 24 months
- Not associated with malignancy
- No cross-hybridization or reactivation by other poxviruses

RISK FACTORS

- Skin-to-skin contact with infected person
- Contact sports
- Swimming
- Eczema, atopic dermatitis
- Sexual activity with infected partner
- Immunocompromised: HIV, chemotherapy, corticosteroid therapy, transplant patients, patients on biologics

GENERAL PREVENTION

- Avoid skin-to-skin contact with host (e.g., contact sports, sexual activity).
- Avoid sharing clothing and towels.

COMMONLY ASSOCIATED CONDITIONS

- Atopic dermatitis
- Immunosuppression medications: corticosteroids, biologics, chemotherapy, etc.
HIV/AIDS

DIAGNOSIS

HISTORY
- Contact with known infected person
- Participation in contact sports
- Sexual activity

PHYSICAL EXAM
- Perform thorough skin exam including conjunctiva and anogenital area.
- Discrete, firm papules with a central umbilication
- White curdlike core under umbilicated center
- Lesions are flesh, pearl, or red in color and frequently located in intertriginous areas.
- May have surrounding erythema or dermatitis
- Immunocompetent hosts: average of 11 to 20 lesions, 2 to 5 mm diameter (range: 1 to 10 mm)
- Immunocompromised hosts may have hundreds of widespread lesions or “giant” molluscum (lesions >1 cm)
- Sexually active: inner thighs, anogenital area

Pediatric Considerations
- Infants <3 months: Consider vertical transmission. If vertical transmission, lesions often located on scalp.
- Children: fever, >50 lesions, limited response to therapy; consider immunodeficiency.
- Children: anogenital lesions; most likely autoinoculation if lesions present elsewhere on body. However, provider should consider possible sexual abuse.

DIFFERENTIAL DIAGNOSIS
- Verruca vulgaris
- Chickenpox
- Milia
- AIDS patients: Cryptococcus neoformans infection, penicilliosis, histoplasmosis, coccidioidomycosis
- Basal cell carcinoma
- Benign appendageal tumors: syringomas, hidrocystomas, ectopic sebaceous glands
- Condyloma acuminatum
- Dermatofibroma
- Eyelid: abscess, chalazion, foreign-body granuloma
- Folliculitis/furunculosis
- Keratoacanthoma
- Oral squamous cell carcinoma
- Trichoepithelioma
- Warty dyskeratoma
- Amelanotic melanoma
- Papular urticaria

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Virus cannot be cultured.
- Culture lesion if concern is secondary infection
- Sexual transmission: Test for other sexually transmitted infections, including HIV.
- Microscopy: scrape lesion
  - Core material has characteristic Henderson-Paterson intracytoplasmic viral inclusion bodies.
  - Crush prep with 10% potassium hydroxide will show characteristic inclusion bodies as well.
  - Alternatively, hematoxylin-eosin-stained formalin-fixed tissue shows same confirmatory features.

Diagnostic Procedures/Other
Clinical exam generally diagnostic. Can use magnifying lens or dermatoscopy to aid in diagnosis.

Test Interpretation
Molluscum cytoplasmic inclusion bodies within keratinocytes

TREATMENT

GENERAL MEASURES
- In healthy patients, molluscum contagiosum is generally self-limited and resolves spontaneously; therefore, treatment is optional (1)[A].
- No single intervention is shown to be convincingly more effective than any other in treating molluscum contagiosum (1)[A].
- There are no Food and Drug Administration (FDA)-approved treatments for molluscum contagiosum.
- Three categories of treatment: destructive, immune-enhancing, and antiviral
- Imiquimod is no longer recommended as treatment.

MEDICATION

First Line
Cantharidin 0.7–0.9% solution: In office application to lesions, cover with dressing; wash off in 2 to 6 hours or sooner if blistering. Repeat treatment every 2 to 4 weeks until lesions resolve (1)[B]. Clearance rate shown to be 15.4–100% (2).
- Not commercially available in the United States but may be prepared in United States by compounding pharmacy from powder; might be available as solution from Canada
- Adverse effects: blistering, erythema, pain, pruritus
- Precautions: Do not use on face or on genital mucosa.

Second Line
- Benzoyl peroxide 10% cream: Apply to each lesion twice daily for 4 weeks (1)[B].
  - Inexpensive, available over the counter
  - Adverse effects: mild dermatitis
- For immunocompromised patients with refractory lesions, consider
  - Starting or maximizing highly active antiretroviral therapy in patients with HIV/AIDS (3)[C]
– Cidofovir
  o 3% cream applied to lesions once daily, 5 days/week for 8 weeks or 1% cream applied to lesions once daily, 5 days/week for 2 weeks; repeat in 1 month, if necessary (3)[C].
  o Adverse effects with topical use: erythema, pain, pruritus, erosions
  o 3 to 5 mg/kg IV weekly for 1 to 2 weeks, followed by IV infusions every other week, until clinical clearance or up to 9 infusions (4)[C]
  o Adverse effects with IV use: nephrotoxicity, neutropenia
  o Monitoring with IV use: renal function and complete blood counts prior to and 24 to 48 hours after infusions
  o Precaution: must coadminister oral probenecid and provide IV hydration with each IV infusion; refer to cidofovir manufacturer’s recommendations on probenecid dosing.

**ISSUES FOR REFERRAL**
Immunocompromised patients not responding to first- or second-line treatment

**SURGERY/OTHER PROCEDURES**
Immunocompromised patients not responding to first- or second-line treatment

**Pregnancy Considerations**
Treatments safe in pregnancy: curettage, cryotherapy, incision, and expression

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Depends on type of treatment
PATIENT EDUCATION
- Cover lesions to prevent spread.
- Avoid scratching to prevent autoinoculation.
- Avoid sharing towels and clothing.
- Avoid sexual activity when lesions present.

PROGNOSIS
- Immunocompetent: self-limited, resolves in 3 to 12 months (range: 2 months to 4 years)
- Immunocompromised: lesions difficult to treat; may persist for years

COMPLICATIONS
- Secondary infection
- Scarring, hyper-/hypopigmentation (generally only occurs as a result of treatment, not when lesions resolve spontaneously)

REFERENCES

ADDITIONAL READING
CODES

ICD10
B08.1 Molluscum contagiosum

CLINICAL PEARLS

- Observation is preferred treatment in healthy patients as lesions will spontaneously resolve.
- Reassure parents that lesions will heal naturally and generally resolve without scarring.
- No specific treatment has been identified as superior to any other, and no treatment is FDA approved.
- Consider topical corticosteroids for pruritus or associated dermatitis.
MORTON NEUROMA (INTERDIGITAL NEUROMA)
J. Herbert Stevenson, MD ● James McKee, DO, MS

BASICS

DESCRIPTION
- Painful condition of the webbed spaces of the toes
- Features perineural fibrosis of the common digital nerve as it passes between metatarsals
  - The interspace between the 3rd and 4th metatarsals is most commonly affected.
  - The interspace between the 2nd and 3rd metatarsals is the next most common site.
- Systems affected: musculoskeletal, nervous
- Synonyms: plantar digital neuritis; Morton metatarsalgia; intermetatarsal neuroma

EPIDEMIOLOGY

Prevalence
- Unknown
- Mean age: 45 to 50 years
- Predominant sex: female > male (8:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Lateral plantar nerve joins a portion of medial plantar nerve, creating a nerve with a larger diameter than those going to other digits.
- Etiology not fully understood. Four main theories:
  - Chronic traction damage
  - Inflammatory environment due to intermetatarsal bursitis
  - Compression by the deep transverse intermetatarsal ligament
  - Ischemia of vasa nervorum
- Nerve lies in SC tissue, deep to the fat pad of foot, just superficial to the digital artery and vein.
- Superficial to the nerve is the strong, deep transverse metatarsal ligament that holds the metatarsal bones together.
- With each step the patient takes, the inflamed nerve becomes compressed between the ground and the deep transverse metatarsal ligament. This can generate perineural fibrotic reaction with subsequent neuroma formation.

RISK FACTORS

- High-heel shoes
  - Transfer more weight to the forefoot.
- Shoes with tight toe boxes
  - Cause lateral compression
- Pes planus (flat feet)
  - Pulls nerve medially, increasing irritation
- Obesity
- Female gender
- Ballet dancing, particularly associated with the demi-pointe position
- Basketball, aerobics, tennis, running, and similar activities
- Hyperpronation
GENERAL PREVENTION
- Wear properly fitting shoes.
- Avoid high heels and shoes with narrow toe boxes.

DIAGNOSIS

HISTORY
- Most common complaint is pain localized to interspace between 3rd and 4th toes.
- Pain is less severe when not bearing weight.
- Pain, cramping, or numbness of the forefoot during weight bearing or immediately after strenuous foot exertion
- Radiation of pain to the toes
- Pain is relieved by removing shoes and massaging the foot.
- Patients often complain of “walking on a marble.”
- Burning pain in the ball of the foot radiating to the toes
- Tingling or numbness in the toes
- Aggravated by wearing tight or narrow shoes

PHYSICAL EXAM
- Intense pain when pressure applied between metatarsal heads, sometimes with a palpable nodule
- Assess midfoot motion and digital motion to determine if arthritis or synovitis.
- Palpate along metatarsal shafts to assess for metatarsalgia or stress fractures.
- Special testing (see “Diagnostic Procedures/Other”)

DIFFERENTIAL DIAGNOSIS
- Stress fracture
- Hammer toe
- Metatarsophalangeal synovitis
- Metatarsalgia
- Arthritis
- Traumatic neuroma
- Osteomyelitis
- Bursitis
- Foreign body
- Freiberg infraction (avascular necrosis of the metatarsal head, most commonly in adolescent females at the 2nd metatarsal)
- Neoplasm (malignancy, osteochondroma, neurofibroma)
- Gout

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Predominantly a clinical diagnosis; imaging should be reserved for when the diagnosis is unclear (1)[A].
- Imaging may be helpful if more than one web space is involved.
- Radiographs may help to rule out osseous pathology if diagnosis is in question, but plain films
usually are normal in patients with a Morton neuroma (1)[A].

- Ultrasound (US) has 79% specificity and 99% sensitivity for Morton neuromas but is poor at assessing the size of the lesion. Specificity declines to 50% for lesions <6 mm (1)[A].
- MRI can rule out an osseous tumor and help with surgical planning; MRI has a sensitivity of 83% and a specificity of 99% for diagnosis of Morton neuroma (1)[A].

Diagnostic Procedures/Other

- Five special tests have been described: thumb index finger squeeze test, Mulder sign, foot squeeze test, plantar percussion test, and toe tip sensation deficit.
  - Thumb index finger squeeze test is the most sensitive and specific (96% and 96%, respectively). Positive when pain elicited by squeezing the symptomatic intermetatarsal space between the index finger and thumb (2)[B].
  - Mulder sign is a painful “click” produced by squeezing the metatarsal heads together while compressing the neuroma between the thumb and index finger of the other hand; sensitivity 40–84% (1)[A].
  - Foot squeeze test is positive when pain is induced in the symptomatic web space when the metatarsal heads are compressed by grasping the foot; sensitivity 40% (2)[B].
  - Plantar and dorsal percussion tests are positive when percussion of the affected webspace elicits pain.
  - Toe tip sensation deficit exists when the sensation of the toe distal to the affected web space is decreased relative to the other toes.

- More than one of the above tests being positive increases the diagnostic accuracy (3)[B].

Test Interpretation

Pathologic examination shows chronic fibrosis and thickening within and around the digital nerve. Arterial thickening and thrombosis of the common digital artery is sometimes present.

**TREATMENT**

**GENERAL MEASURES**

- Stepwise treatment, with typical progression from conservative measures followed by infiltrative treatment and ultimately surgical treatment.

- Surgical treatments are the most successful (89%) followed by infiltrative (84%), then conservative (48%), as assessed by patient satisfaction with pain reduction at 6 months or greater (4)[A].

- Conservative treatments include
  - Flat shoes with a roomy toe box
  - Plantar pads or metatarsal bar may help with alignment of metatarsal heads to provide relief.
  - There is no role for varus or valgus footwear padding (5).
  - There is no role for Extracorporeal Shock Wave Therapy (ESWT) (5).

- NSAIDs for temporary symptom relief (6)[A]

**MEDICATION**

**First Line**

- Injectable steroids (e.g., betamethasone phosphate/acetate or methylprednisolone): number needed to treat (NNT) for significant benefit over conservative measures at 6 months = 2.3 (4)
One study demonstrated clinically significant improvement in use of US guidance versus palpation for corticosteroid injection (8).

**Second Line**

US-guided alcohol ablation therapy to sclerose the nerve is effective and has a lower complication rate than surgery (4)[A].

**ISSUES FOR REFERRAL**
- Continued pain despite conservative treatments and injections
- Large interdigital neuromas (>5 mm diameter) or young patients who may benefit from earlier operative intervention
- One study demonstrated that a cut-off value of 6.3 mm or larger Morton neuroma was associated with failure of corticosteroid injection (9)[B].

**SURGERY/OTHER PROCEDURES**
- Surgical removal of the neuroma or shortening of the metatarsals, with or without release of the transverse metatarsal ligament, has an 89% success rate at 6 months defined by satisfaction scores (4)[A].
- Small trials have been conducted using other invasive, nonsurgical techniques including injection with botulinum toxin, cryoablation, radiofrequency ablation, and platelet-rich plasma, but evidence is limited at this time.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
At diagnosis, or if no improvement after 3 months of conservative treatment, consider corticosteroid injection.
- May repeat injection if no improvement after 2 to 4 weeks, or consider referring for surgical management.
- 21–51% of patients receiving a single corticosteroid injection require surgical intervention within 2 to 4 years (10)[B].
- Size >5 mm and younger patients are more likely to undergo invasive treatment (10)[B].

**PATIENT EDUCATION**
Wear properly fitting comfortable shoes.

**PROGNOSIS**
- 48% satisfaction rate with conservative treatment
- 85% satisfaction rate with infiltrative treatment
- 89% satisfaction rate with operative treatment (4)[A]

**COMPLICATIONS**
- Hip and knee pain can develop secondary to gait changes.
- Complications vary by treatment type.
- Failure rate is 47% with conservative treatment; 9–23% with invasive, nonsurgical treatment; 4% with surgical treatment (4)[A].
Surgical complications vary by specific procedure and include keloid, CRPS, and stiffness. There was a global complication rate of 21% with operative treatment (4)[A].

REFERENCES

ADDITIONAL READING

CODES

ICD10
- G57.60 Lesion of plantar nerve, unspecified lower limb
- G57.61 Lesion of plantar nerve, right lower limb
- G57.62 Lesion of plantar nerve, left lower limb

CLINICAL PEARLS
Morton neuroma is usually a clinical diagnosis but can be further evaluated with US or MRI. Typical treatment is stepwise with conservative, then infiltrative, and then operative treatment. Morton neuromas with >5 mm diameter are more likely to require operative treatment. Younger patients are more likely to require operative treatment. Neurectomy is the definitive treatment. Patients should be aware of surgical complications.
MOTION SICKNESS
Gina Henry, MD ● Alexandra Jubran, DO, MPH ● Cory N. Mitchell, MD

BASICS

DESCRIPTION
- Motion sickness is a physiologic response in affected individuals to a situation in which sensory conflict about body motion exists among visual receptors, vestibular receptors, and body proprioceptors.
- Also can be induced when patterns of motion differ from those previously experienced
- System affected: nervous, gastrointestinal
- Synonym(s): car sickness; sea sickness; air sickness; space sickness; physiologic vertigo

EPIDEMIOLOGY

Incidence
Predominant sex: female > male

Prevalence
Estimation is complex; syndrome occurs in ~25% due to travel by air, ~29% by sea, and ~41% by road. Estimates for vomiting are 0.5% by air, 7% by sea, and 2% by road.

ETIOLOGY AND PATHOPHYSIOLOGY
- Precise etiology unknown; thought to be due to a mismatch of vestibular and visual sensations
- Rotary, vertical, and low-frequency motions produce more symptoms than linear, horizontal, and high-frequency motions.
- Nausea and vomiting occur as a result of increased levels of dopamine and acetylcholine, which stimulate chemoreceptor trigger zone and vomiting center in CNS.

Genetics
Heritability estimates range from 55% to 75%.

RISK FACTORS
- Motion (auto, plane, boat, amusement rides)
- Visual stimuli (e.g., moving horizon)
- Poor ventilation (fumes, smoke, carbon monoxide)
- Emotions (fear, anxiety)
- Zero gravity
- Pregnancy, menstruation, oral contraceptive use
- History of migraine headaches, especially vestibular migraine

GENERAL PREVENTION
See “General Measures.”

Pediatric Considerations
- Rare in children <2 years of age
- Incidence peaks between 3 and 12 years of age.
- Antihistamines may cause excitation in children.

**Geriatric Considerations**
- Age confers some resistance to motion sickness.
- Elderly are at increased risk for anticholinergic side effects from treatment.

**Pregnancy Considerations**
- Pregnant patients are more likely to experience motion sickness.
- Treatment with medications is thought to be safe during morning sickness (e.g., meclizine, dimenhydrinate).
- Scopolamine, meclizine, diphenhydramine, and promethazine generally considered safe during breastfeeding

**COMMONLY ASSOCIATED CONDITIONS**
- Migraine headache
- Vestibular syndromes

**DIAGNOSIS**

**HISTORY**
Presence of the following signs and symptoms in the context of a typical stimulus (1):
- Nausea
- Vomiting
- Stomach awareness (feeling of fullness in epigastrium)
- Diaphoresis
- Facial and perioral pallor
- Hypersalivation
- Yawning
- Hyperventilation
- Anxiety
- Panic
- Malaise
- Fatigue
- Weakness
- Confusion
- Dizziness

**PHYSICAL EXAM**
No specific findings

**DIFFERENTIAL DIAGNOSIS**
- Mountain sickness
- Vestibular disease, central and peripheral
- Gastroenteritis
- Metabolic disorders
- Toxin exposure
**DIAGNOSTIC TESTS & INTERPRETATION**

None usually indicated, can consider pregnancy test

---

**TREATMENT**

- Follow guidelines under “General Measures” section to prevent motion sickness (1)[C].
- Premedicate before travel with antidopaminergic, anticholinergic, or antihistamine agents (1)[A]:
  - For extended travel, consider treatment with scopolamine transdermal patch (2)[A].
- Conflicting data exist on the efficacy of acupressure for nausea and vomiting associated with motion sickness (3)[B].
- Benzodiazepines suppress vestibular nuclei but would not be considered first line due to sedation and addiction potential (4)[C].
- Serotonin receptor agonist (rizatriptan) may be effective for migraineurs with motion sickness (5)[C].

**GENERAL MEASURES**

- Avoid noxious types of motions. Travelling in inclement weather may exacerbate symptoms.
- Improve ventilation; avoid noxious stimuli.
- Eat before travel (light, soft, bland, low-fat, and low-acid foods); avoid alcohol; avoid empty stomach.
- Increase airflow around face.
- Use semirecumbent seating or lay supine.
- Fix vision on horizon; avoid fixation on moving objects; keep eyes fixed on still, distant objects.
- Avoid reading while actively traveling.
- Frequent and graded exposure to stimulus that triggers nausea (habitation)
- Counsel patient on minimizing motion (airplanes: over the wing; automobiles: driver’s or front passenger seat, facing forward; boat: facing toward the waves, away from rocking bow, near surface of the water; buses: near the front, at lowest level, facing forward; trains: at lowest level, facing forward).
- Acupressure on point PC6 (Neiguan on pericardium meridian) has been shown to reduce feelings of nausea and vomiting during pregnancy, after surgery, and in cancer chemotherapy. However, limited evidence of efficacy has been found for motion sickness; point PC6: 2 cm proximal of transverse crease of palmar side of wrist between tendons of the palmaris longus and the flexor carpi radialis (3)[B].

**MEDICATION**

**First Line**

- Scopolamine transdermal patch (Transderm Scop; $25.56 each): Apply 2.5-cm$^2$ (4 mg) patch behind ear over the mastoid at least 4 hours (preferably 6 to 12 hours) before travel and replace every 3 days (2)[A].
- Promethazine (Phenergan; $0.49 each 12.5 mg): Take 30 to 60 minutes before travel.
  - Adults: 25 mg q12h; 25 to 50 mg IM if already developed severe motion sickness
  - Children and adolescents: 0.5 mg/kg q12h, maximum 25 mg BID; caution: increased risk of dystonic reaction in this age group
Dimenhydrinate (Dramamine; $0.30 each 50 mg): Take 30 to 60 minutes before travel.
  - Adults and adolescents: 50 to 100 mg q4–6h, maximum 400 mg/day
  - Children 6 to 12 years of age: 25 to 50 mg q6–8h, maximum 150 mg/day
  - Children 2 to 5 years of age: 12.5 to 25.0 mg q6–8h, maximum 75 mg/day
Meclizine (Travel Ease; $0.03 each 25 mg): Take 60 minutes before travel.
  - Adults and adolescents >12 years of age: 25 to 50 mg q24h
  - Children <12 years of age: not recommended
Diphenhydramine (Benadryl; $0.02 to 0.06 per 25 mg): Take 30 minutes before travel.
  - Adults and adolescents: 25 to 50 mg q6–8h, maximum 300 mg/day
  - Children 6 to 12 years of age: 5 mg/kg or 12.5 to 25.0 mg q4–6h, maximum 150 mg/day
Contraindications: patients at risk for acute angle-closure glaucoma.
Precautions:
  - Young children
  - Elderly
  - Pregnancy
  - Urinary obstruction
  - Pyloric duodenal obstruction
Adverse reactions:
  - Drowsiness
  - Dry mouth
  - Blurred vision
  - Confusion
  - Headache
  - Urinary retention
Significant possible interactions:
  - Sedatives (antihistamines, alcohol, antidepressants)
  - Anticholinergics (belladonna alkaloids)

Second Line
Benzodiazepines: Take 1 to 2 hours before travel.
  - Diazepam 2 to 10 mg PO q6–12h
  - Lorazepam 1 to 2 mg PO q8h
Contraindications:
  - Severe respiratory dysfunction
  - Severe liver dysfunction
Precautions:
  - Alcohol/drug abuse
  - Elderly
  - Sedation
  - Addiction is possible.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Ginger: 1.0 to 1.5 g per 24 hours (250 mg 4 times a day); take 4 hours before travel; studies have shown ginger to be an effective treatment for nausea and vomiting (6)[B].
ONGOING CARE

DIET
- Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods.
- Avoid alcohol.

PROGNOSIS
- Symptoms should resolve when motion exposure ends.
- Resistance to motion sickness seems to increase with age.

COMPLICATIONS
- Hypotension
- Dehydration
- Depression
- Panic
- Syncope

Algorithm: Dizziness

CODES
ICD10
The scopolamine transdermal patch is first line for prevention of motion sickness. It should be applied at least 4 hours before travel, although it is most effective if placed 12 hours before departure.

First-generation antihistamines are also effective, although sedating. They should be administered 30 to 60 minutes before departure.

Nonsedating antihistamines, ondansetron, and ginger root are not effective in the prevention or treatment of motion sickness.

Although acupressure wristbands have been found to be effective by systematic reviews in postoperative and chemotherapy-induced nausea and vomiting, as well as hyperemesis gravidarum, conflicting data exist for use with motion sickness.
MULTIPLE MYELOMA
Tyler R. Reese, MD, FAAFP

**BASICS**

**DESCRIPTION**
- Multiple myeloma (MM) is a clonal proliferation of malignant plasma cells.
- This clonal proliferation in the bone marrow (BM) can cause extensive skeletal destruction with osteolytic lesions and pathologic fractures.
- The malignant plasma cells produce monoclonal protein in the blood and urine.
- MM is also characterized by hypercalcemia, increased susceptibility to infections, renal impairment, and end-organ damage.
- Monoclonal gammopathy of undetermined significance (MGUS) is a common disorder with limited monoclonal plasma cell proliferation that can progress to MM at rate of ~1% per year.
- MGUS can progress to smoldering or asymptomatic MM and eventually to symptomatic MM.
- Synonym(s): plasma cell myeloma; plasma cell leukemia

**EPIDEMIOLOGY**
- Accounts for nearly 2% of all cancers and 17% of hematologic malignancies in the United States
- Median age of diagnosis is 66 years.
- Slight male predominance. Blacks about 2 to 3 times more commonly affected than whites; less common in Asians.

**Incidence**
4 to 5 new cases per 100,000 annually in the United States

**Prevalence**
In 2018, there were nearly ~160,000 recognized cases worldwide (1)[A].

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Clonal proliferation of plasma cells derived from postgerminal center B cells
- Plasma cells undergo multiple chromosomal mutations to progress to MM.
- Genetic damage in developing B lymphocytes at time of isotype switching, transforming normal plasma cells into malignant cells, arising from single clone
- Earliest chromosomal translocations involve immunoglobulin (Ig) heavy chains on chromosome 14q32, with the translocation at t(4;14), t(14;16), t(14;20), and deletion, del(17p) having a poorer prognosis (2)[C].
- Malignant cells multiply in BM, suppressing normal BM cells and producing large quantities of monoclonal Ig (M) protein.
- Malignant cells stimulate osteoclasts that cause bone resorption and inhibit osteoblasts that form new bone, causing lytic bone lesions.

**Genetics**
Rare family clusters; the hyperphosphorylated form of paratarg-7, a protein of unknown significance, is inherited as an autosomal dominant trait in familial cases of MM and MGUS,
suggesting a potential pathogenic role.

**RISK FACTORS**
- Most cases have no known risks associated.
- Older age; immunosuppression; and chemicals like dioxin, herbicides, insecticides, petroleum, heavy metals, plastics, and ionizing radiation increase the risk of MM.
- MGUS stage consistently precedes MM.

**COMMONLY ASSOCIATED CONDITIONS**
Secondary amyloidosis commonly due to MM

**DIAGNOSIS**

**HISTORY**
- 34% of patients are asymptomatic at the time of presentation.
- Hypercalcemia (28%): anorexia, abdominal pain, somnolence, polydipsia, polyuria, dehydration
- Elevated creatinine (48%)
- Anemia (73%)
- Bony lesions (80%): lytic lesions causing bone pain (58%) (3)[C], osteoporosis, or pathologic fracture (26–34%)
- Other symptoms: fatigue (32%), peripheral neuropathy (PN), weight loss (24%), recurrent infections, hyperviscosity syndrome, and cord compression

**PHYSICAL EXAM**
- Dehydration
- Skin findings of amyloidosis: waxy papules, nodules, or plaques that may be evident in the eyelids, retroauricular region, neck, or inguinal and anogenital regions; petechiae and ecchymosis; “pinch purpura”
- Extramedullary plasmacytomas can present as large, purplish, subcutaneous masses.
- Hyperviscosity syndrome in 7%: retinal hemorrhages, prolonged bleeding, neurologic changes
- Tender bones and masses

**DIFFERENTIAL DIAGNOSIS**
- MGUS
- Smoldering MM (SMM)
- Metastatic carcinoma (kidney, breast, non–small-cell lung cancer)
- Waldenström macroglobulinemia
- AL amyloidosis
- Solitary plasmacytoma
- Polyneuropathy, organomegaly, endocrinopathy, M protein, skin changes (POEMS) syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**
Criteria for diagnosis: The diagnosis of MM requires the following (4)[C]:
- BM involvement with $\geq$10% of plasma cells or the presence of a plasmacytoma and any one or more of the following myeloma-defining events:
  - Evidence of end-organ damage that can be attributed to the underlying plasma cell
proliferative disorder, specifically:
  - Hypercalcemia: serum calcium >0.25 mmol/L (>1 mg/dL) higher than the upper limit of normal or >2.75 mmol/L (>11 mg/dL)
  - Renal insufficiency: creatinine clearance <40 mL/min or serum creatinine >177 μmol/L (>2 mg/dL)
  - Anemia: hemoglobin value of >2 g/dL below the lower limit of normal or a hemoglobin value <10 g/dL
  - Bone lesions: one or more osteolytic lesions on skeletal radiography, computed tomography (CT), or positron emission tomography (PET)-CT
    - Any one or more of the following biomarkers of malignancy:
      - Clonal BM plasma cell percentage ≥60%
      - Involved:uninvolved serum free light chain (FLC) ratio ≥100
      - >1 focal lesion on magnetic resonance imaging (MRI) studies

### Initial Tests (lab, imaging)
- Complete blood count with differential to evaluate anemia and other cytopenias with evaluation of peripheral blood smear
- Blood urea nitrogen, creatinine (elevated creatinine due to myeloma cast nephropathy)
- Serum electrolytes, serum albumin, serum calcium
- Serum lactate dehydrogenase (LDH), β2-microglobulin
- Serum protein electrophoresis (SPEP), serum immunofixation electrophoresis (SIFE): M protein level elevated
- Quantitative serum Ig levels: IgG, IgA, and IgM
- Quantitative serum FLC levels: κ and λ chains
- ESR, C-reactive protein: elevated
- Urine analysis: 24-hour urine for protein, urine protein electrophoresis (UPEP), urine immunofixation electrophoresis (UIFE); 20% positive urine protein (3)[C]:
  - Urinalysis dip is often negative for protein because this test identifies albumin, and the protein in MM is Bence Jones (BJ) monoclonal protein.
- CRAB: hypercalcemia, renal insufficiency, anemia, and bone lesions
- Cross-sectional imaging (whole body, low-dose CT) is preferred over plain radiographs for the detection of bone involvement (4)[C].
- Skeletal surveys are reserved for patients who are unable to undergo low-dose whole body CT, MRI, and PET.

### Follow-Up Tests & Special Considerations
- For patients with suspected SMM (no bone lesions on CT), a whole body MRI or MRI of the spine and pelvis is recommended to evaluate for cord compression.
- For patients with suspected extramedullary disease outside of the spine, a whole body PET-CT is recommended.
  - Baseline bone densitometry may be indicated (5)[A].
  - BM aspiration and biopsy for histology, immunohistochemistry, flow cytometry, cytogenetics, and fluorescence in situ hybridization (FISH) as well as to monitor response to treatment
  - SPEP with SIFE: M protein helps to track progression of myeloma and response to treatment.
  - Serum Igs and FLCs can be used to monitor response or relapse.
  - Plasma cell labeling index may be helpful to identify the fraction of the myeloma cell population that is proliferating (5)[A].
Diagnostic Procedures/Other

Staging to determine disease burden (2)[C]:

- Durie-Salmon stage
  - Stage I: low tumor cell mass: <0.6 × 10^{12} cells/m^2 plus all of the following: hemoglobin >10 g/dL, M protein <5 g/dL if IgG or <3 g/dL if IgA, normal serum calcium, urine BJ protein <4 g/24 hr, no generalized lytic bone lesions
  - Stage II: neither stage I nor stage III
  - Stage III: high tumor cell mass: >1.2 × 10^{12} cells/m^2 plus one or more of the following: hemoglobin <8.5 g/L, serum calcium >12 mg/dL, bone lesions, M protein >7 g/dL if IgG and >5 g/dL if IgA, urine BJ protein >12 g/24 hr, advanced lytic bone lesions

- International Staging System (ISS)
  - Stage I: albumin ≥3.5 g/dL and β_2-microglobulin <3.5 μg/mL
  - Stage II: neither stage I nor stage III
  - Stage III: β_2-microglobulin ≥5.5 μg/mL
  - Revised ISS (R-ISS) combines ISS information with chromosomal abnormalities and LDH to provide better prognostic information for MM.

- Mayo Stratification of Myeloma and Risk-Adapted Therapy (mSMART)
  - Standard risk: t(11;14), t(6;14), and hyperdiploidy
  - Intermediate risk: t(4;14), del(13q) by cytogenetics, hypodiploidy
  - High risk: t(14;16), t(14;20), del(17 p), and plasma cell labeling index >3%

Test Interpretation

BM involvement with plasma cells ≥10%; Russell bodies

TREATMENT

- Treatment varies depending on level of disease activity and stage of MM.
- Key determinant factor in choosing chemotherapy regimen is to establish if the patient is an autologous stem cell transplant (ASCT) candidate or not.
- Treatment protocols vary by institution and patient.
- ASCT following induction chemotherapy is standard of care for patients with symptomatic disease.

GENERAL MEASURES

Maintain adequate hydration to prevent renal insufficiency. All patients receiving primary myeloma therapy should be given bisphosphonates initially (5)[A].

MEDICATION

- Induction chemotherapy for ASCT-eligible patients (6)[C]:
  - Preferred treatments for transplant candidates: bortezomib/lenalidomide/dexamethasone or bortezomib/cyclophosphamide/dexamethasone (preferred in acute renal insufficiency)
  - Other recommended regimens: bortezomib/doxorubicin (or thalidomide)/dexamethasone, carfilzomib/lenalidomide/dexamethasone or ixazomib/lenalidomide/dexamethasone (where cyclophosphamide can replace lenalidomide for select circumstances)
  - Three-drug regimens are preferred; two-drug regimens can be used for elderly or frail patients.
  - Lenalidomide is recommended for maintenance therapy after ASCT; lower rates of
progressive disease but higher rates of second primary cancers
  – Bortezomib or ixazomib are an option for maintenance therapy after ASCT.

**Induction chemotherapy for ASCT-ineligible patients:**
  – Same regimens as ASCT-eligible patients as well as lenalidomide/low-dose dexamethasone or daratumumab/lenalidomide/dexamethasone
  – Other recommended regimens: carfilzomib/lenalidomide/dexamethasone, daratumumab/bortezomib/melphalan/prednisone, or ixazomib/lenalidomide/dexamethasone
  – Lenalidomide or bortezomib are options for maintenance therapy for non-ASCT patients after primary treatment.

**First Line**

**Proteasome inhibitors (6)**
  – Blocks ubiquitin-proteasome catalytic pathway in cells by binding to the 20S proteasome complex
  – Consider herpes simplex virus (HSV) prophylaxis.
  – Bortezomib: IV or SC; SC has lower risk of PN. Toxicity: PN, cytopenia, nausea, anorexia, leukopenia, thrombocytopenia, rash
  – Carfilzomib: IV, 2nd-generation proteasome inhibitor. Better progression free survival and overall survival than bortezomib. Toxicity: fever, diarrhea, anemia, thrombocytopenia, fatigue; can have hypersensitivity reaction after infusion
  – Ixazomib—PO. Toxicity: PN, diarrhea, thrombocytopenia, neutropenia, back pain, edema

**Cyclophosphamide**
  – Nitrogen mustard–derivative alkylating agent
  – Often used in combination with prednisone or thalidomide in cases of relapsed disease
  – Toxicity: cytopenia, anaphylaxis, interstitial pulmonary fibrosis, secondary malignancy, impaired fertility

**Immunomodulators**
  – Daratumumab: IgGκ1 monoclonal Ab against CD38. Toxicity: fatigue, back pain, lymphocytopenia, neutropenia, anemia, thrombocytopenia, cough, infusion-related reaction
  – Thalidomide and lenalidomide

**Dexamethasone**
  – Low doses (40 mg/wk) superior to higher doses
  – Increases risk of DVT

**Bisphosphonates (5) [A]**
  – No effect on mortality but decrease pain, pathologic vertebral fractures, and fractures of other bones
  – No evidence of superior outcomes for any particular aminobisphosphonate or nonaminobisphosphonate; zoledronate was shown to be better than placebo and etidronate for improving certain outcomes.
  – Dose-adjust/monitor renal function.
  – Monitor for osteonecrosis of jaw.

**Second Line**

**Multiple regimens can be used as salvage therapy to treat relapsed or refractory myeloma (6).**

**If relapse occurs >6 months after completing initial primary treatment, can use same regimen for retreatment**

**Elotuzumab: IgG1 immunostimulatory monoclonal antibody directed against CS1 (SLAMF7).**
Toxicity: fatigue, PN, hyperglycemia, hypocalcemia, infection, cough

**ISSUES FOR REFERRAL**
For spinal or other bone pathology, refer to orthopedics for support.

**ADDITIONAL THERAPIES**
- Local radiation therapy for bone pain
- Effective pain management; avoid nonsteroidal anti-inflammatory drugs (NSAIDs) due to nephrotoxicity.
- Aspirin 81 to 325 mg is recommended for patients treated with immunomodulators.
- Kyphoplasty/vertebroplasty: Consider for symptomatic vertebral compressions.
- Plasmapheresis for hyperviscosity syndrome
- Erythropoietin for selected patients with anemia
- Patients should receive vaccines for pneumococcus and influenza.
- Do not administer live-virus vaccines (3).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Indications: pain, infections, cytopenia, renal failure, bone complications, spinal cord compression
- Avoid IV radiographic contrast materials due to risk for contrast-induced nephropathy.
- Adequate hydration
- Manage hypercalcemia and control hyperuricemia.

**ONGOING CARE**

**PATIENT EDUCATION**
- [https://myeloma.org](https://myeloma.org)
- [http://www.nccn.org/patients/guidelines/myeloma/](http://www.nccn.org/patients/guidelines/myeloma/)

**PROGNOSIS**
- The 5-year survival rate is around 50%.
- Median survival by R-ISS stage:
  - Stage I: has not been reached
  - Stage II: 83 months
  - Stage III: 43 months
- Median survival in patients with high-risk MM (see staging for definition) is <2 to 3 years, even after ASCT; standard risk has median overall survival of 6 to 7 years.

**COMPLICATIONS**
Many, including infection, pain, lytic bone lesions, hypercalcemia, hyperuricemia, spinal cord compression, anemia, hyperviscosity syndrome, amyloidosis, renal insufficiency

**REFERENCES**

**CODES**

**ICD10**
- C90.00 Multiple myeloma not having achieved remission
- C90.01 Multiple myeloma in remission
- C90.02 Multiple myeloma in relapse

**CLINICAL PEARLS**
- MM is a plasma cell malignancy that causes end-organ damage.
- Look for presence of “CRAB.”
- Suspect MM if high total protein-to-albumin ratio is present.
- Maintain high index of suspicion for spinal cord compression.
- Avoid nephrotoxins (radiographic contrast material, NSAIDs, dehydration).
- Patients with MM are immunocompromised.
MULTIPLE SCLEROSIS
Jack R. Stacey, MD ● Andrew J. McDermott, MD, FAAFP

BASICS
DESCRIPTION
- An autoimmune disease directed against components of the neural myelin sheath causing demyelination often leading to progressive axonal loss and eventual central nervous system (CNS) atrophy affecting primarily white matter but may also damage grey matter and overlying meninges
- Four clinical subtypes of multiple sclerosis (MS):
  - Clinically isolated syndrome (CIS): a patient’s initial symptom characteristic of CNS demyelination that may be due to MS but does not fulfill the criteria of dissemination in time. Approximately 60% of individuals diagnosed with CIS will later relapse and be diagnosed with MS.
  - Relapsing-remitting multiple sclerosis (RRMS): episodic flare-ups occurring over days to weeks between periods of neurologic stability. During attacks, new symptoms may present, whereas previous symptoms may worsen. Complete recovery of residual deficits may ensue following each bout (~90% of patients).
  - Secondary progressive multiple sclerosis (SPMS): a gradual decline in disease status after an initial relapsing-remitting disease course. Progressive phase may be associated with acute exacerbations. SPMS is often diagnosed retrospectively.
  - Primary progressive multiple sclerosis (PPMS): a progressive decline in disease status and accumulation of disability from onset of disease without an initial relapsing-remitting disease course (~10% of patients) (1)

Pregnancy Considerations
- Pregnancy is not precluded in MS; however, multidisciplinary pregnancy planning is essential.
- In most cases, MS treatment should be discontinued during pregnancy.
- A majority of patients experience reduced disease exacerbations during pregnancy, but frequency of relapse typically increases in the postpartum period.
- MS therapy should be promptly resumed after delivery, particularly for individuals with very active disease prior to conception.
- All drugs licensed for MS treatment are contraindicated during breastfeeding. Patients desiring to breastfeed should carefully consider risk of delaying MS treatment (2).

EPIDEMIOLOGY
MS is a complex condition that is multifactorial, and although advances in genomics and immunology have increased our understanding of the disease process, much is yet to be discovered. It most often affects Caucasian women in their 2nd and 3rd generations of life and is more common in those with first-degree relatives with the disease.

Incidence
- Women (worldwide): 3.6 cases per 100,000 person-years
- Men (worldwide): 2.0 cases per 100,000 person-years
Prevalence
- United States: ~400,000 MS patients
- Worldwide: ~2,500,000 MS patients

Etiology and Pathophysiology
- Predominately an autoimmune process driven by T cells and B cells against the myelin sheath. Dysregulation and mistaken antigen identity lead CD4 T cells to cross the blood–brain barrier and recognize proteins on the surface of the myelin sheath. Cytokines, interferon-γ, and tumor necrosis factor-α are subsequently released, and activation of macrophages and B cells leads to oligodendrocyte and myelin destruction.
- Following demyelination, faster salutatory nerve conduction velocities (impulses jumping between nodes of Ranvier) are replaced with considerably slower continuous nerve velocities. These changes in the acute setting lead to the focal neurologic deficits associated with MS.
- Oligodendrocytes, which have survived, or ones formed from precursor cells, are able to partially remyelinate stripped axons, producing scars that over time can lead to irreversible axonal loss and brain atrophy.
- The majority of axons are typically lost from the lateral corticospinal (motor) tracts of the spinal cord. MS was once thought to be a disease of strictly affecting white matter tracts; however, there is increasing evidence of inflammatory damage within the cortical grey matter and overlying meninges (1).

Genetics
- MS is polygenic and does not follow a mendelian inheritance pattern. Those with affected first-degree relatives are 5 to 7 times more likely to be diagnosed.
- Over 100 genetic loci have been associated with MS suggesting that it is ultimately an antigen-specific autoimmune process. Most commonly, these are mapped to the class II region of the HLA gene cluster. The most common being the HLA-DRB1 locus on chromosome 6. These produce major histocompatibility complexes with high-binding affinity for myelin basic proteins.
- Although not fully understood, variations of natural killer cells and their polymorphic killer-immunoglobulin-like receptors are thought to play a major role in the MS disease process (1).

Risk Factors
- Age: peak incidence ages 15 to 45 years, mean age 28 to 31 years (slightly earlier in women than men)
- Race: Caucasian > Afro-Caribbean > East-Asian
- Gender: 2 to 3 times more common in women
- Infectious: prior infections with Epstein-Barr virus and history of infectious mononucleosis
- Substance: tobacco smoking
- Geographic: Historically, proximity to the equator and its correlation with increased vitamin D exposure were inversely proportional to MS incidence. However, recently this association has been less obvious and may be due to lifestyle changes that have led to decreased sun exposure in these locations (1).

General Prevention
No known prevention strategies

Commonly Associated Conditions
Internuclear ophthalmoplegia: Injury to the medial longitudinal fasciculus causes impaired adduction of the affected eye.
Optic neuritis: inflammation of optic nerve resulting in loss of vision
Associated with numerous other autoimmune processes

DIAGNOSIS
A person with MS can present with a number of neurologic signs and symptoms depending on the locations of the lesion. The essential means of diagnoses is to demonstrate evidence of CNS lesions that are separated by both time and space that are not more likely due to a separate disease process.

HISTORY
Symptoms can vary widely but may include fatigue, epilepsy, dizziness, visual disturbances, facial palsy, dysphagia, muscle weakness or spasms, hyperesthesia or paresthesia, pain, bowel or bladder incontinence, urinary frequency or retention, or impotence (1).

PHYSICAL EXAM
- Weakness
- Internuclear ophthalmoplegia
- Gait disturbance
- Foot drop
- Hyperesthesia or paresthesia
- Cerebellar dysarthria (scanning speech)
- Spasticity (especially in lower extremities)
- Uhthoff phenomenon: Symptoms worsen with exposure to higher than usual temperature.
- Lhermitte sign: electric-like shocks extending down the spine caused by neck movement, especially flexion

DIFFERENTIAL DIAGNOSIS
- Lyme disease
- Systemic lupus erythematosus
- Antiphospholipid antibody syndrome
- Neuromyelitis optica
- Epilepsy
- Progressive multifocal leukoencephalopathy
- CNS neoplasms
- Guillain-Barré syndrome
- Metachromatic leukodystrophy
- Neurosarcoidosis
- Stroke
- Primary cerebral angiitis
- Neurosyphilis
- Cobalamin (vitamin B_{12}) deficiency
- Acute disseminated encephalomyelitis
- Behçet disease
- Normal pressure hydrocephalus
DIAGNOSTIC TESTS & INTERPRETATION

- MRI of head/spine: Periventricular and callosal lesions are relatively specific for MS. The additions of gadolinium can help identify active lesions.

- Lumbar puncture: Cerebrospinal fluid can reveal elevated or normal total protein levels. Oligoclonal immunoglobulin G bands are seen in approximately 90% of MS but may be absent early in the disease process. Positive findings are not diagnostic for MS but may be beneficial if other diagnostic criteria are equivocal.

- Blood tests: Antinuclear antibody, antineutrophil cytoplasmic antibody, anti-double-stranded DNA antibody, extractable nuclear antigen, antiphospholipid antibody, complement, erythrocyte sedimentation rate, immunoglobulin G, immunoglobulin M, rheumatoid factor, and Lyme disease antibody can be used to rule out alternative diagnosis (1)[B],(3).

- McDonald criteria for diagnosing MS: must demonstrate dissemination in space and time of CNS lesions (4)[C]
  - Dissemination in space: ≥1 T2 lesion on MRI in at least 2 of 4 CNS regions typically affected by MS: periventricular, juxtacortical, infratentorial, or spinal cord or by waiting for another clinical event implying a different CNS location
  - Dissemination in time: simultaneous presentation of asymptomatic gadolinium-enhanced and nonenhancing lesions at any moment or a new T2 and/or gadolinium-enhanced lesion on an MRI when compared with baseline scans

Diagnostic Procedures/Other

Evoked potentials: Assess function of visual, auditory, and somatosensory motor CNS pathways by measuring CNS electric potentials evoked by neural stimulation. A marked delay, without a clinical manifestation, is suggestive of a demyelinating disorder. Visual evoked potentials are delayed in 80–90% of individuals with MS (1).

TREATMENT

GENERAL MEASURES

- Holistic multidisciplinary team approach is paramount.

- Three main categories currently exist for MS treatment: treatment for acute relapses, treatment for reducing MS-related activity using disease-modifying agents, and symptomatic therapy.

- The use of disease-modifying treatments early in the disease process is likely to slow overall disease progression and should be managed by a MS specialist (1)[C].

MEDICATION

- Acute relapse treatment (1,5)[A]
  - Methylprednisolone 0.5 g PO daily for 5 days or 1 g IV daily for 3 to 5 days; without subsequent oral tapering; a second course may be given.
    - Side effects: increased infection risk, adrenal insufficiency, Cushing syndrome, fluid retention, hypokalemia, GI disturbances, headache, emotional lability
  - ACTH gel 80 U IM or SC daily for 5 to 15 days
    - Side effects: similar to methylprednisolone
    - Plasmapheresis

- Disease-modifying treatment (1,6)[B]
- IFN-β1a (Avonex) 30 µg IM weekly
- IFN-β1a (Rebif) 22 or 44 µg SC 3 times per week
- IFN-β1b (Betaseron/Betaferon/Extavia) 250 µg SC every other day
  - Monitoring: CBC, LFTs, TSH
  - Side effects: flu-like symptoms, depression, skin site reactions, thyroid dysfunction, liver enzyme abnormalities
- Glatiramer acetate (Copaxone) 20 mg SC daily
  - Monitoring: none
  - Side effects: skin site reactions, immediate postinjection reaction, lipoatrophy
- Dimethyl fumarate (Tecfidera) 120 to 240 mg PO twice daily
  - Monitoring: CBC, LFTs
  - Side effects: diarrhea, cramps, LFT elevation, nausea, flushing
- Teriflunomide (Aubagio) 7 to 14 mg PO daily
  - Monitoring: CBC, LFTs, UA
  - Side effects: nasopharyngitis, headache, diarrhea, fatigue, back pain, influenza, hair thinning, LFT elevation, nausea, urinary tract infection (UTI)
- Natalizumab (Tysabri) 300 mg IV every 28 days
  - Monitoring: CBC, LFTs
  - Side effects: headache, fatigue, UTI, hypersensitivity reaction
- Alemtuzumab (Lemtrada) 12 to 24 mg IV for 5 days, then 3 days 12 months after initial treatment
  - Monitoring: CBC, LFTs, TSH
  - Side effects: immune thrombocytopenic purpura, autoimmune thyroid-related problems, headaches, flushing
- Fingolimod (Gilenya) 0.5 mg PO daily
  - Monitoring: ECG, CBC, LFTs, eye exam
  - Side effects: 1st degree AV block, bradycardia, macular edema, shingles, worsening pulmonary function, skin cancer, back pain

**Symptomatic therapies (1)**

- Spasticity: baclofen, dantrolene, diazepam, tizanidine, cannabis extract (nabiximols), botulinum toxin, physiotherapy
- Pain: amitriptyline, pregabalin, gabapentin, cannabis extract (nabiximols)
- Bladder dysfunction: oxybutynin, tolterodine, cannabis extract (nabiximols), catheterization, intravesical botulinum toxin
- Constipation: natural or other laxatives, stool softeners, bulk-producing agents
- Erectile dysfunction: sildenafil
- Fatigue: amantadine, modafinil
- Tremors: clonazepam, primidone, β-blockers
- Depression: SSRI (citalopram), SNRI (venlafaxine), TCA (amitriptyline)
- Walking: fampridine

**ADDITIONAL THERAPIES**

- Cognitive behavioral therapy
- Physical, occupational, and speech therapy
- Yoga and water-based exercise
- Massage therapy
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Assessing the severity of neurologic impairment from MS can be done using the Kurtzke Expanded Disability Status Scale (EDSS): The EDSS quantifies severity of disability using eight functional systems (FS): pyramidal, cerebellar, brainstem, sensory, bowel and bladder, visual, and cerebral. EDSS scoring system (7)[C]:

- 1.0—no disability, minimal signs in 1 FS
- 2.0—minimal disability in 1 FS
- 3.0—moderate disability in 1 FS or mild disability in 3 to 4 FS, but fully ambulatory
- 4.0—ambulatory without aid or rest for ~500 m
- 5.0—ambulatory without aid or rest for ~200 m
- 6.0—intermittent/constant unilateral assistance (cane, crutch, or brace); must be able to walk 100 m
- 7.0—unable to walk beyond 5 m even with aid; essentially restricted to wheelchair, wheels self and transfers alone; active in wheelchair for ~12 hr/day
- 8.0—essentially restricted to bed, chair, or wheelchair; may be out of bed most of the day; retains self-care functions, generally effective use of arms
- 9.0—helpless, bedbound; but patient can communicate, eat
- 10.0—death due to MS

DIET
High fiber and fluids to prevent constipation

PATIENT EDUCATION
National Multiple Sclerosis Society: 1-800-344-4867 or www.nationalmssociety.org/

PROGNOSIS
- Differs in each individual based on numerous factors
- Approximately half of all patients will be unable to maintain a career 10 years after MS onset.
- Almost a third of patients will ultimately be wheelchair bound.
- Average life expectancy is 5 to 10 years less than the unaffected population (1).

COMPLICATIONS
Mortality secondary to MS relapse is unusual; death more commonly associated with a complication of MS such as infection in a person with more disability

REFERENCES

CLINICAL PEARLS

- MS is an immune-mediated inflammatory disease causing demyelination, neuronal loss, and scarring within the CNS.
- Diagnosis is made with the McDonald criteria and must demonstrate damage to the CNS disseminated in space and time.
- Disease treatments consist of acute relapse, disease-modifying agents, and symptomatic therapies.
- MS treatment modalities are complex and rapidly changing. A patient’s treatment should be guided by a MS specialist, but multiprofessional therapy is necessary.
- New approaches to manipulate inflammation, neurodegeneration, and remyelination such as hematopoietic stem cell transplants are being tested in clinical trials and may dramatically alter treatment and prevention of MS in the future (1).
MUMPS
Frances Y. Wu, MD, FAAFP

BASICS
An acute, self-limited, generalized paramyxovirus infection typically presenting with unilateral or bilateral parotitis

DESCRIPTION
- Can be asymptomatic in 1/3 of nonimmune individuals and 60% of previously vaccinated cases
- Painful parotitis in 95% of symptomatic mumps cases
- Epidemics in late winter and spring; transmission by respiratory secretions
- Incubation period is 14 to 24 days.
- System(s) affected: hematologic/lymphatic/immunologic, reproductive, skin, exocrine
- Synonym(s): epidemic parotitis; infectious parotitis

EPIDEMIOLOGY
- 85% of mumps cases occur prior to 15 years of age.
- Adult cases are typically more severe.
- Predominant sex: male = female
- Geriatric population: Most adults are immune.
- Acute epidemic mumps
  - Most cases occur in unvaccinated children 5 to 15 years of age.
  - Multiple recent outbreaks in U.S. college students
- Mumps is unusual in children <2 years of age.
- Period of maximal communicability is 24 hours before to 72 hours after onset of parotitis.

Incidence
- From January 1 to July 19, 2019, 1,799 cases reported in United States from 45 states and District of Columbia
- Since 1967 (start of national vaccination program), case rate has dropped from 100/100,000 to 1.1/100,000.
- Occasional regional epidemic outbreaks

Prevalence
- 0.0064/100,000 persons in United States
- 90% of adults are seropositive.

ETIOLOGY AND PATHOPHYSIOLOGY
Mumps is an RNA virus (rubulavirus) of the Paramyxovirus genus. Mumps virus replicates in glandular epithelium of parotid gland, pancreas, and testes, leading to interstitial edema and inflammation.
- Interstitial glandular hemorrhage may occur.
- Pressure caused by testicular edema against the tunica albuginea can lead to necrosis and loss of function.
RISK FACTORS

- Foreign travel: Most of Africa, southern Asia, and Japan do not vaccinate for mumps. Only two thirds of all countries vaccinate routinely for mumps.
- Crowded environments such as dormitories, barracks, or detention facilities increase risk of transmission.
- Immunity wanes after single-dose vaccination. With 2-dose schedule, immunity drops from 95% to 86% after 9 years.

GENERAL PREVENTION

- Vaccination
  - 2 doses of live mumps vaccine or mumps, measles, rubella (MMR) vaccine recommended, first at 12 to 15 months and second at 4 to 6 years. Start at 6 months if foreign travel is planned.
  - 95% effective in clinical studies; field trials show 68–95% efficacy, which may be insufficient for herd immunity to prevent spread.
  - Prevention may require 95% first dose and >80% second-dose adherence. Vaccine failure may increase 10–27% each year after vaccination.
  - Adverse effects: fever 8/100,000; seizure 25/100,000; thrombocytopenic purpura 3/100,000
  - No relationship between MMR vaccine and autism, celiac disease, or multiple sclerosis. Recent data show a reduced autism risk in girls after MMR vaccination (aHR 0.79, overall for both genders aHR 0.93) (1).
- Immunoglobulin (Ig) does not prevent mumps.
- Postexposure vaccination does not protect from recent exposure (2)[B].
- Isolate hospitalized patients for 5 days after onset.
- Isolate nonimmune individuals for 26 days after last case onset (social quarantine).
- In an epidemic situation, a third dose of MMR is indicated to decrease the attack rate (3)[A].
- Vaccine neutralizing antibodies are still effective against variant strains of mumps virus.
- Although there are no reports of disseminated mumps from MMR vaccine in HIV patients, live vaccines (MMR) are contraindicated in immunocompromised patients (e.g., HIV with CD4 <200).

Pregnancy Considerations

- Live viral vaccines are typically contraindicated in pregnancy; however, vaccination of children should not be delayed if a family member is pregnant.
- Immunization of contacts protects against future (but not current) exposures.

DIAGNOSIS

HISTORY

- Parotid swelling peaks in 1 to 3 days; lasts 3 to 7 days
- Clinical diagnosis (swelling of one or both parotid glands):
  - Lasting ≥2 days
  - No other apparent cause
  - Meningitis without parotitis (rare; 1–10%)
- 1/3 of individuals with mumps may be asymptomatic.
- Rare prodrome of fever, neck ache, and malaise
- Sour foods cause pain in parotid gland region.
- Moderate fever, usually not >104°F (40°C):
  - High fever frequently is associated with complications.

PHYSICAL EXAM
- Painful parotid swelling (unilateral or bilateral) obscures angle of mandible and elevates earlobe.
- Meningeal signs (15%); encephalitis (<1%)
- 2–6% orchitis, polyarthritis, thyroiditis, mastitis, pancreatitis, oophoritis, myocarditis, profound hearing loss. Complications may occur after days to weeks.
- Rare maculopapular, erythematous rash
- Up to 50% of cases are mild.
- Redness at opening of Stensen duct without pus
- Sternal swelling (rare and pathognomonic for mumps)

DIFFERENTIAL DIAGNOSIS
- If not epidemic, other viruses are more common: influenza, parainfluenza parotitis, Epstein-Barr virus, coxsackievirus, adenovirus, parvovirus B19, influenza parotitis—several hundred reported in 2016.
- Suppurative parotitis: often associated with Staphylococcus aureus (Presence of pus within Wharton duct with parotid massage essentially excludes diagnosis of mumps.)
- Recurrent allergic parotitis
- Salivary calculus with intermittent swelling
- Lymphadenitis from any cause, including HIV infection
- Cytomegalovirus parotitis (immunocompromised)
- Mikulicz syndrome: chronic, painless parotid and lacrimal gland swelling of unknown cause that occurs in tuberculosis, sarcoidosis, lupus, leukemia, lymphosarcoma, and salivary gland tumors
- Sjögren syndrome, diabetes mellitus, uremia, malnutrition
- Drug-related parotid enlargement (iodides, guanethidine, phenothiazine)
- Complications of mumps: 1–10% meningoencephalitis, orchitis, oophoritis, pancreatitis, polyarthritis, nephritis, myocarditis, prostatitis
- Mumps orchitis must be differentiated from testicular torsion and from chlamydial or bacterial orchitis.

DIAGNOSTIC TESTS & INTERPRETATION
- Buccal swab and serum tests recommended https://www.cdc.gov/mumps/lab/specimen-collect.html
  - IgM titer (positive by day 5 in 100% of nonimmunized patients), rapid EIA for IgM
  - Swab of fluid from parotid duct or other affected salivary ducts after gland massage for rRT-PCR plus viral culture—send to state lab or CDC; most sensitive day 1 to day 3 of parotitis, especially important for vaccinated persons
  - Rise in IgG titer samples; if not previously immunized: first sample within 5 days of onset and second 2 weeks later. Previously vaccinated persons may not mount a 4-fold IgG increase, nor a significant IgM
- Urine for PCR (not as sensitive as oral specimens) may not be positive until 4 days or more after symptom onset. 50 mL in sterile container. Send to state lab (or recognized public health
Other potential findings: elevated serum amylase, CSF leukocytosis, or leukopenia.

Testicular ultrasound may help differentiate mumps orchitis from testicular torsion.

Diagnostic Procedures/Other
If meningitis symptoms present, lumbar puncture to exclude bacterial process; CSF pleocytosis, usually lymphocytic, in 65% of patients with parotitis.

Test Interpretation
Periductal edema and lymphocytic infiltration of affected glands on biopsy.

TREATMENT
- No specific antiviral therapy; supportive care [A]
- Immediately place mask on patients with any suspected mumps exposures who present for evaluation
- Analgesics to relieve pain
- Avoid corticosteroids for mumps orchitis because they can reduce testosterone and increase testicular atrophy.
- IVIG can reduce certain autoimmune-based sequelae:
  - Postinfectious encephalitis, Guillain-Barré syndrome, ITP
- Interferon-α2b improves bilateral orchitis but not testicular atrophy [B].

GENERAL MEASURES
- Hospitalize patients with high fever, pancreatitis, or CNS symptoms for supportive care, steroids, or interferon. Use isolation precautions.
- Orchitis
  - Ice packs to scrotum can help to relieve pain.
  - Scrotal support with adhesive bridge while recumbent and/or athletic supporter while ambulatory

MEDICATION
First Line
- Analgesics and anti-inflammatory medications (acetaminophen, nonsteroidal anti-inflammatory drugs [NSAIDs]) may diminish pain and swelling in acute orchitis and arthritis of mumps.
- May use acetaminophen for fever and/or pain
- Precautions: Avoid aspirin for pain in children as previously associated with Reye syndrome.

Second Line
Interferon-α2b [B]

COMPLEMENTARY & ALTERNATIVE MEDICINE
Medicinal herbs or acupuncture have not shown benefit in randomized controlled trials.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Hospitalize only if CNS symptoms occur.
- Outpatient supportive care if no complications.
• IV fluids if severe nausea or vomiting accompanies pancreatitis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Mumps orchitis:
• Bed rest and local supportive clothing (e.g., two pairs of briefs) or adhesive-tape bridge
• Withhold from school until no longer contagious (9 days after onset of pain).

**Patient Monitoring**
Most cases will be mild. Monitor hydration status.

**DIET**
Liquid diet if unable to chew

**PATIENT EDUCATION**
Orchitis is common in older children but rarely results in sterility, even if bilateral.

**PROGNOSIS**
• Complete recovery is typical; immunity is lifelong.
• Transient sensorineural hearing loss in 4% of adults
• Recurrence after 2 weeks may be nonepidemic other viral parotitis, but mumps RNA has been found in some recurrent parotitis swabs.

**COMPLICATIONS**
• May precede, accompany, or follow salivary gland involvement and may occur (rarely) without primary involvement of the parotid gland
• Orchitis more common (6–30%) in postpubertal boys:
  – Starts within 8 days of onset of parotitis
  – Impaired fertility in 13%; absolute sterility is rare.
• Meningitis may present 5 to 10 days after first symptoms. Aseptic meningitis is typically mild, but meningoencephalitis may lead to seizures, paralysis, hydrocephalus, or (in 2% of encephalitis cases) death.
• Acute cerebellar ataxia has been reported after mumps infections; self-resolving in 2 to 3 weeks
• Oophoritis in 7% of postpubertal females; no decreased fertility. Mastitis has been reported in females.
• Pancreatitis, usually mild
• Nephritis, thyroiditis, and arthralgias are rare.
• Myocarditis: usually mild but may depress ST segment; may be linked to endocardial fibroelastosis
• Deafness: 1/15,000 unilateral nerve deafness; may not be permanent
• Inflammation about the eye (keratouveitis) is rare.
• Dacryoadenitis, optic neuritis

**Pediatric Considerations**
• Orchitis is more common in adolescents.
Young children are less likely to develop complications. Most complications occur in postpubertal group. Avoid aspirin use in children with viral symptoms.

Pregnancy Considerations
May increase risk of spontaneous pregnancy loss in first trimester. Perinatal mumps often has a benign course.

REFERENCES

ADDITIONAL READING

SEE ALSO
CDC Surveillance Manual

CODES
ICD10
- B26.3 Mumps pancreatitis
- B26.2 Mumps encephalitis
- B26.81 Mumps hepatitis

CLINICAL PEARLS
Mumps is a clinical diagnosis based on swelling of ≥1 parotid glands for ≥2 days without other obvious cause. Confirm with buccal swab PCR, viral culture, and IgM and IgG serology to identify early in epidemic setting. Work with local health authorities if necessary to ensure
appropriate specimen collection.
- Report positive results to public health authorities.
- Ultrasound helps distinguish testicular torsion from testicular pain related to mumps orchitis.
- A history of vaccination with MMR does not exclude mumps.
- The MMR vaccine is 68–95% effective after two immunizations. Immunity wanes over time.
MUSCULAR DYSTROPHY
Nimmy Thakolkaran, MD ● George G.A. Pujalte, MD, FACSM

BASICS
- Primary inherited myopathies caused by dysfunctional proteins of muscle fibers and extracellular matrix
- Distribution of weakness, other associated symptoms, and disease prognosis depend on the specific gene affected and severity of the mutation

DESCRIPTION
- Duchenne muscular dystrophy (DMD)
  - Highest incidence muscular dystrophy, X-linked inheritance, early onset, progressive
  - Patients are wheelchair-dependent by age 13 years.
- Becker muscular dystrophy (BMD)
  - Less severe phenotype compared to DMD; also caused by mutation in DMD gene; later onset and milder clinical course
  - Distinction from DMD is clinical: Patients are usually wheelchair-dependent by age 16 years.
  - Collectively referred to as dystrophinopathies
- Myotonic muscular dystrophy (MMD)
  - Myotonia (slow relaxation after muscle contraction), distal and facial weakness
  - Second most common inherited muscle disease
- Facioscapulohumeral muscular dystrophy (FSHMD)
  - Facial and shoulder muscles most affected
  - Third most common inherited muscle disease
- Limb-girdle muscular dystrophy (LGMD)
  - Proximal weakness and atrophy, variable prognosis with many different identified mutations
- Oculopharyngeal muscular dystrophy (OPMD)
  - Usually adult-onset, affects extraocular and pharyngeal muscles; presents with ptosis and dysphagia
- Emery-Dreifuss muscular dystrophy (EDMD)
  - Triad of early development of joint contractures, slowly progressive muscle wasting, and cardiomyopathy; can present as sudden death in apparently healthy, young adults
- Congenital muscular dystrophies (CMD)
  - Heterogeneous group of autosomal recessive myopathic diseases presenting in infancy, with generally poor prognosis
  - Include Fukuyama CMD, Ullrich CMD, Walker-Warburg syndrome, muscle-eye-brain disease

EPIDEMIOLOGY
Incidence
- Duchenne: 1/3,600 male births
- Myotonic dystrophy: 1/10,000 births
CMD: 0.99 per 100,000
Other muscular dystrophies vary widely by population but are generally rare.

ETIOLOGY AND PATHOPHYSIOLOGY
Mutations affect proteins connecting cytoskeleton to cell membrane and extracellular matrix, causing muscle fibers to become fragile and easily damaged; muscle weakness and atrophy result.

DMD/BMD
- Defective protein is dystrophin, product of the largest human gene, DMD; Duchenne phenotype results from mutations that cause profound loss of dystrophin, the protein involved in calcium transport in muscle cells and stabilizing fibers during contraction.
- Becker phenotype results from less severe mutations in DMD gene; patients have low but detectable levels of functional dystrophin.

MMD: Trinucleotide repeat expansion in the untranslated region of the gene DMPK on chromosome 19; encodes myotonin–protein kinase

LGMD: mutations in genes encoding proteins associated with dystrophin: Calpain-, dysferlin-, and fukutin-related proteins are affected most commonly.

EDMD: Dysfunctional proteins are associated with the nuclear membrane in muscle fibers; emerin in X-linked form, lamin A/C in autosomal forms

OPMD: Trinucleotide repeat expansion in PABPN1 results in nuclear inclusions in muscle cells by hampering normal transport of mRNA from the nucleus.

FSHMD: deletion in untranslated region of chromosome 4; function of deleted genes is unclear, although the most accepted concept is that they likely affect the expression of multiple genes by epigenetic effects.

Genetics
- X-linked
  - Duchenne and Becker muscular dystrophies
    - Gene located at Xp21
      - 30% of affected males have a de novo mutation (mother is not a carrier).
      - 20% of female carriers have some manifestation of the mutation (usually mild muscle weakness or cardiomyopathy).

- Autosomal dominant
  - Generally later onset and less severe than diseases with recessive or X-linked inheritance
  - FSHMD, OPMD, some forms of LGMD and EDMD

- Myotonic dystrophy
  - Trinucleotide repeat expansion with more severe phenotype in subsequent generations due to accumulation of repeats

- Autosomal recessive
  - Most types of CMD

GENERAL PREVENTION
Genetic counseling for carriers and prenatal diagnosis

COMMONLY ASSOCIATED CONDITIONS
- Decreased IQ: on average, 1 SD below the mean in DMD; speech and language delay
- Dilated cardiomyopathy and conduction abnormalities
  - Can be severe in EDMD
– Can affect otherwise asymptomatic female carriers of DMD
– Progressive scoliosis

**DIAGNOSIS**

**HISTORY**

- DMD: normal attainment of early motor milestones with subsequent abnormal gait and slowing gross motor development: clumsiness, waddling gait, frequent falls, difficulty running or climbing stairs
- BMD: progressive difficulty with ambulation and frequent falls in later childhood
- MMD: slurred speech, muscle wasting, difficulty with ambulation; often with family history
- LGMD: back pain; lordosis/inability to rise from a chair, climb stairs, and use arms overhead
- FSHMD: facial weakness, inability to close eyes completely
- EDMD: contractures of elbows and ankles, difficulty with ambulation in teenage years
- OPMD: ptosis and dysphagia; often with family history

**PHYSICAL EXAM**

- **DMD/BMD**
  - Proximal muscle weakness; Gower sign: use of arms to push upper body into standing posture from lying prone
  - Trendelenburg gait (asymmetric hip waddling)
  - Hyporeflexia/areflexia
  - Winged scapulae and lordosis
  - Pseudohypertrophy of the calf (caused by replacement of muscle with fibroadipose tissue)
  - Contractures of lower extremity joints and elbows
- **MMD**
  - Characteristic facial appearance: narrow face, open triangular mouth, high-arched palate, concave temples, drooping eyelids, frontal balding in males
  - Myotonia: inability to relax muscles after contraction
  - Distal muscle weakness and wasting
- **CMD**
  - Arthrogryposis (multiple joint contractures); diffuse hypotonia and muscle wasting in an infant

**DIFFERENTIAL DIAGNOSIS**

- Glycogen storage diseases and other metabolic myopathies
- Mitochondrial myopathies: MELAS (Mitochondrial Encephalopathy, Lactic Acidosis, and Stroke-like episodes), MERRF (Myoclonus with Epilepsy and Ragged-Red Fibers)
- Inflammatory myopathies: polymyositis, dermatomyositis, inclusion-body myositis
- Neuromuscular junction diseases: myasthenia gravis, Lambert-Eaton syndrome
- Motor neuron diseases: amyotrophic lateral sclerosis, spinal muscular atrophy
- Charcot-Marie-Tooth disease
- Friedreich ataxia

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Creatine kinase (CK): Initial screening test if MD is suspected (2)[A]
Elevated in DMD (10 to 100 times); elevated at birth, peaks at time of presentation, and falls during illness
Initial detected lab abnormality may be elevated aspartate transaminase/alanine transaminase (AST/ALT) originating from muscle.
Genetic testing/molecular diagnosis
  – For definitive diagnosis in patient with characteristic presentation and elevated CK
  – Deletion and duplication analysis (MLPA or CGH) will identify most patients (70–80%), followed by genomic sequencing of DMD gene for point mutations (20–30% of patients) (3)[A].
  – Genetic testing is available clinically for most other muscular dystrophies.

Diagnostic Procedures/Other
Muscle biopsy: rarely performed in DMD (dystrophin protein absent); can be used for dystrophin analysis if genetic testing fails to find a mutation
Electromyography and nerve conduction studies are not necessary unless considering alternative diagnoses.
ECG: abnormalities found in >90% of males and up to 10% of female carriers of DMD; Q waves in anterolateral leads, tall R waves in V1, shortened PR interval, arrhythmias, resting sinus tachycardia

Test Interpretation
Heterogenic muscle fibers: atrophy and hypertrophy of fibers with proliferation of connective tissue in muscle
Immunohistochemical staining for dystrophin protein
  – DMD: no detectable dystrophin in most fibers; occasional revertant fibers with normal dystrophin
  – BMD: highly variable staining for dystrophin throughout muscle

TREATMENT
Glucocorticoid treatment is the only available therapy that affects disease progression. Novel drugs that affect gene expression are now available; however, their clinical benefits have yet to be seen.

GENERAL MEASURES
  ● Ambulation prolonged by knee-ankle-foot orthoses
  ● Serial casting to treat contractures
  ● Diagnose sleep apnea with polysomnography; treat with noninvasive ventilation.
  ● Adaptive devices to improve function
  ● Avoid overexertion and strenuous exercise.

MEDICATION
Glucocorticoids:
  ● Prednisone (0.75 mg/kg/day) (4)[A] or Deflazacort (0.9 mg/kg/day)—a synthetic oral corticosteroid, which has been found to cause less weight gain than prednisone (5)
  ● Slows the decline in muscle function, progression to scoliosis, and degradation of pulmonary
function; prolongs functional ambulation; prolongs lifespan; improved cardiac outcomes

- Therapy should be initiated when there is no longer progress in motor skills, but prior to decline (2).
- Monitor adverse effects.
  - Add dietary calcium and Vitamin D supplementation. Yearly DXA scanning and bisphosphonates should be considered for preventing loss of bone density; annual exam for cataracts; hypertension should be monitored; no NSAIDs due to risk of peptic ulcer disease (PUD); stress-dose steroids during surgeries and illnesses due to adrenal suppression
  - Patients should be aware of immune suppression and notify emergency providers.
- ACE inhibitors
  - Treatment of cardiomyopathy; may be used in conjunction with \( \beta \)-blockers

**ISSUES FOR REFERRAL**

- Refer to neuromuscular diseases center for definitive diagnosis and coordinated multidisciplinary care (4).
- Cardiology for management of cardiomyopathy
- Pulmonology for monitoring of pulmonary function and clearance regimen
- Physical medicine and rehabilitation for management of adaptive devices
- Nutrition/swallowing: for normal weight gain, attention for dysphagia
- Psychosocial: learning/behavior and coping assessment, social development (2)
- Orthopedics: for surgical correction of scoliosis

**ADDITIONAL THERAPIES**

2 novel medications:
- Eteplirsen—for patients with mutations of dystrophin gene amenable to exon 51 skipping; approximately 13% of DMD patients
- Ataluren—interferes with premature stop codons, allowing expression of dystrophin protein in patients with nonsense mutation; approximately 15% of DMD patients

**SURGERY/OTHER PROCEDURES**

- Spinal surgery for scoliosis diminishes rate of deformity progression (6)[A].
- Scapular fixation for scapular winging may be beneficial; however, also lacking clinical trials.
- Consider surgical treatment of ankle/knee contractures.
- Surgical procedures should be performed at a center experienced in DMD; total IV anesthesia should be used.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Whole body vibration exercises

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Recognize and mitigate adrenal suppression resulting from corticosteroid dependence (6).

**ONGOING CARE**

- Individualized education plan and developmental evaluation for school accommodations
- Maintenance of current influenza and pneumococcal vaccination status

**FOLLOW-UP RECOMMENDATIONS**
Patient Monitoring
- Electrocardiogram (ECG), echocardiogram, and consultation with a cardiologist at diagnosis and annually after age 10 years
  - Female carriers of DMD mutation should be monitored every 5 years.
- Annual spinal radiography for scoliosis
- Dual-energy x-ray absorptiometry (DEXA) scanning and serum marker testing for osteoporosis
- Pulmonary function testing twice yearly if no longer ambulatory
- Psychosocial: coping, emotional adjustment, depression

Diet
- Obesity is common due to steroid treatment and wheelchair confinement: Weight control can improve quality of life.
- Diet may be limited by dysphagia; swallow evaluation can determine appropriate foods; may require gastrostomy
- Calcium and vitamin D supplementation for patients on steroids; monitor vitamin D levels.

Patient Education
- Muscular Dystrophy Association: http://www.mda.org
- Parent Project Muscular Dystrophy: http://www.parentprojectmd.org
- Cure Duchenne: https://www.cureduchenne.org

Prognosis
- DMD/BMD
  - Progressive weakness, contractures, inability to walk
  - Kyphoscoliosis and progressive decline in respiratory vital capacity with recurrent pulmonary infections
  - Significantly shortened lifespan (DMD: 16 ± 4 years; BMD: 42 ± 16 years). Respiratory failure cause of death in 90%; remaining due to myocardial disease (heart failure and dysrhythmia) (7)
- Other types: slow progression and near-normal lifespan with functional limitations

Complications
- Cardiac arrhythmia, cardiomyopathy
- Dysphagia, gastroesophageal reflux disease (GERD), constipation
- Scoliosis, joint contractures
- Obstructive sleep apnea
- Malignant hyperthermia–like reaction to anesthesia
- Respiratory failure and early death

References

ADDITIONAL READING

CODES

ICD10
- G71.0 Muscular dystrophy
- G71.11 Myotonic muscular dystrophy
- G71.2 Congenital myopathies

CLINICAL PEARLS
- Primary care providers should have a low threshold to obtain serum CK as a screening test in the face of gross motor delay/muscular weakness, especially in boys.
- Steroids should be initiated in patients with DMD when gross motor function ceases to progress.
- High-quality care of patients requires a medical home; a multidisciplinary team of physicians, therapists, and other providers; and extensive patient and family support.
MYALGIC ENCEPHALOMYELITIS/CHRONIC FATIGUE SYNDROME (CFS)
Grant M. Reed, DO ● Jessica Lowry, PhD

BASICS

DESCRIPTION
- A chronic and complex physical illness characterized by a new or definitive onset of debilitating fatigue that persists for >6 months and significantly reduces a person’s ability to perform pre-illness activities. Key features include (1):
  - Impaired memory or concentration
  - Joint and muscle pain
  - Unrefreshing sleep
  - Post-exertional malaise (PEM)
  - Orthostatic intolerance (i.e., dizziness and light-headedness when standing up)
- Synonyms: myalgic encephalomyelitis (ME), chronic Epstein-Barr virus syndrome, postviral fatigue syndrome, chronic fatigue immune dysfunction, and systemic exertion intolerance disease
- Fatigue is not relieved by rest and results in >50% reduction in pre-illness activities (occupational, educational, social, and personal).
- Other potential medical causes must be ruled out.

EPIDEMIOLOGY
- Usually seen as sporadic or in isolated cases, although cluster outbreaks in school-age children have occurred around the world: Iceland (1948); London, England (1955); New Zealand (1984); and the United States (1984 and 1985).
- Can affect all ages; incidence peaks at 10–19 years and 30–39 years (1)
- More female than male adults are affected
- Estimated annual cost (direct and indirect) $17–24 billion

Prevalence
- Affects all racial and ethnic groups; more prevalent in minority and low socioeconomic groups
- Estimated at 519 to 1,038 diagnosed per 100,000; as extrapolated from the US population (2017) an estimated 1.7 to 3.38 million patients may suffer from ME or CFS.

ETIOLOGY AND PATHOPHYSIOLOGY
Cause is unknown and most likely multifactorial—a combination of genetics, initiating stressors, and perpetuating factor(s):
- Suspected initiating stressors:
  - Viral, bacterial, or parasitic infection: Epstein-Barr virus (EBV), retroviruses, Lyme disease, Q fever, human herpesvirus type 6, enteroviruses, Ross river virus, Borna disease virus
  - Significant physical or emotional trauma
  - Recent vaccination
  - Overexertion
  - Chronic sleep deprivation
— Toxin exposure (e.g., organophosphate pesticides) or an atypical adverse reaction to a medication

### Suspected perpetuating factors include:
— Delay in diagnosis and consequently disease management
— Overexertion
— Stress
— Inadequate sleep
— Co-morbid conditions, such as orthostatic intolerance

### Hypothesized contributing systems and factors include:
— Cellular metabolism (e.g., reduced oxidative phosphorylation and mitochondrial function)
— Neuroendocrine system (e.g., diminished cortisol response to increased corticotropin concentrations)
— Immune system (e.g., increased pro-inflammatory cytokines, C-reactive protein, and \( \beta_2 \)-microglobulin)
— Muscular system (e.g., reduced glucose and oxygen uptake)
— Autonomic system (e.g., orthostatic hypotension)
— Serotonergic system (e.g., hyperserotonergic mechanisms or upregulation of serotonin receptors)
— Gastrointestinal system (e.g., increased wall permeability, altered gut microbiota, IBS co-morbidity)

### Genetics
— Higher concordance in monozygotic twins than dizygotic twins
— Genetic polymorphisms in several neuroimmunoendocrine-related genes have been reported and may contribute to the risk of developing disease (2)
— Due to the historical occurrence of ME/CFS outbreaks, there may be a common predisposing genetic mutation that is hidden by the rare combination of trigger events required to induce a disease phenotype.

### RISK FACTORS
— Family history of ME or CFS
— Personality characteristics (neuroticism and introversion)
— Comorbid depression or anxiety
— Long-standing medical and/or mental health conditions in childhood
  — Childhood inactivity or overactivity
  — Childhood trauma (emotional, physical, or sexual abuse)
— Prolonged idiopathic chronic fatigue

### COMMONLY ASSOCIATED CONDITIONS
— Fibromyalgia (more common in women)
— Irritable bowel syndrome (IBS)
— Gynecologic conditions (pelvic pain, endometriosis) and surgeries (hysterectomy, oophorectomy)
— Anxiety disorders and/or major depressive disorders
— Post-traumatic stress disorder (PTSD), including physical and/or past sexual abuse
— Domestic violence
— Attention deficit hyperactivity disorder (ADHD)
Postural orthostatic tachycardia syndrome (POTS)
Sleep disorders, including obstructive sleep apnea (OSA)
Reduced left ventricular size and mass
Prolapsed mitral valve
Temporomandibular joint syndrome
Multiple chemical sensitivities
Migraines
Myofascial pain syndrome
Hashimoto thyroiditis
Raynaud phenomenon
Interstitial cystitis
Sicca syndrome
Allergies

DIAGNOSIS

HISTORY

A thorough medical history and psychosocial history is required for an accurate diagnosis. The 2015 diagnostic criteria proposed by the Institute of Medicine (IOM) (1) require three symptoms and at least one of the two additional manifestations:

- A substantial reduction or impairment in the ability to engage in pre-illness levels of activity (occupational, educational, social, or personal life) that:
  - Lasts for 6 months
  - Is accompanied by fatigue that is:
    - Often profound
    - Of new onset (not lifelong)
    - Not the result of ongoing or unusual excessive exertion
    - Not substantially alleviated by rest
- Post-exertional malaise*—worsening of symptoms after physical, mental, or emotional exertion that would not have caused a problem before the illness. PEM often puts the patient in relapse that may last days, weeks, or even longer.
- Unrefreshing sleep*—patients with ME/CFS may not feel better or less tired even after a full night of sleep despite the absence of specific objective sleep alterations.
- At least one of the following two additional manifestations must be present:
  - Cognitive impairment*—patients have problems with thinking, memory, executive function, and information processing as well as attention deficit and impaired psychomotor functions. All can be exacerbated by exertion, effort, prolonged upright posture, stress, or time pressure and may have serious consequences on a patient’s ability to maintain a job or attend school full time.
  - Orthostatic intolerance—patients develop a worsening of symptoms upon assuming and maintaining upright posture as measured by objective heart rate and blood pressure abnormalities during standing, bedside orthostatic vital signs, or head-up tilt testing. Orthostatic symptoms including lightheadedness, fainting, increased fatigue, cognitive worsening, headaches, or nausea are worsened with quiet upright posture (either standing or sitting) during day-to-day life and are improved (although not necessarily fully resolved) with lying down. Orthostatic intolerance is often the most bothersome manifestation of
ME/CFS among adolescents.  
*The frequency and severity of these symptoms need to be evaluated.

**PHYSICAL EXAM**
Complete physical exam to rule out other medical causes for symptoms. A complete mental status examination should be performed as well.

**DIFFERENTIAL DIAGNOSIS**
- Idiopathic chronic fatigue (i.e., fatigue of unknown cause for >6 months without meeting criteria for CFS)
- Psychiatric disorders: depression, anxiety, somatization disorder, substance abuse
- Physiologic fatigue: poor sleep hygiene, menopause, pregnancy until 3 months postpartum
- Sleep disorders (e.g., insomnia, sleep apnea, narcolepsy)
- Endocrine disorders (e.g., hypothyroidism, Addison disease, Cushing syndrome, diabetes mellitus)
- Chronic infections
  - Lyme disease
  - Fungal disease (e.g., histoplasmosis, coccidioidomycosis)
  - Parasitic disease (e.g., amebiasis, giardiasis, helminth infestation)
  - HIV or related diseases
  - Tuberculosis
  - Chronic hepatitis B/C
  - Chronic or subacute bacterial diseases (e.g., endocarditis, occult abscess)
- Iatrogenic (e.g., medication side effects)
- Toxic agent exposure
- Obesity
- Malignancy
- Autoimmune diseases
- Chronic inflammatory diseases (e.g., sarcoidosis, Wegener’s disease, Celiac disease, inflammatory bowel disease)
- Neuromuscular diseases (e.g., multiple sclerosis, myasthenia gravis, Parkinson’s disease)
- Cardiovascular diseases (e.g., cardiomyopathy or other causes of heart failure)

**DIAGNOSTIC TESTS & INTERPRETATION**
No validated diagnostic test is available. Note that an abnormal result is not always the same as discovering the cause of fatigue. Renew the search if the suspected problem is treated and the patient remains fatigued.

**Initial Tests (lab, imaging)**
Standard laboratory tests are recommended to rule out other causes for symptoms:
- CBC; complete metabolic panel
- Urinalysis
- Thyroid-stimulating hormone (TSH) and free thyroxine (free $T_4$)
- ESR or C-reactive protein
- Magnesium and phosphorus level
- Vitamin B12 and serum folate
- Creatine kinase (CK)
- 25-hydroxy-cholecalciferol (Vitamin D)
• Serum iron, iron-binding capacity, ferritin
• Screen for domestic violence:
  – “Have you ever been hit, kicked, punched, or otherwise hurt by someone within the past year? If so, by whom?”
  – “Do you feel safe in your current relationship?”
  – “Is there a partner from a previous relationship who is making you feel unsafe now?”

Follow-Up Tests & Special Considerations
• Additional laboratory studies, based on clinical features:
  – Antinuclear antibodies and rheumatoid factor
  – Tuberculin skin test
  – Serum cortisol
  – HIV; RPR; VDRL
  – Lyme serology
  – IgA tissue transglutaminase
• Consider age/gender-appropriate cancer screening.
• Consider an electroencephalogram and/or magnetic resonance imaging if the patient has central nervous system symptoms.
• Consider polysomnography and/or multiple sleep latency test (MSLT) if the patient has features of a sleep disorder.
• Consider urine drug screening in those with concerning historical features.
• Assess for personality and psychosocial factors and maladaptive coping styles.

TREATMENT
• No treatment has been proven effective by large randomized trials; recommendations are based on expert opinion and standard symptom management (e.g., sleep disturbances, depression, and pain).
• Focus on changes in lifestyle and insight with a goal to avoid complicating treatments (e.g., addictive medications, invasive testing) or interventions that support secondary gain.
• A multidisciplinary approach is recommended.

GENERAL MEASURES
Treatment involves symptom control and guided self-management. The aim is to reduce symptoms and improve quality of life. Identify the most troublesome symptoms (pain and insomnia) and address those first. While cognitive-behavioral therapy (CBT) and graded exercise therapy (GET) were originally described as effective, recent criticism concerning inadequate trial design suggests that more research is required.
• Individual CBT: Not curative; may improve coping strategies and/or assist in rehabilitation (e.g., social, occupational).
• GET: Track amount of exercise patient can do without exacerbating symptoms and gradually increase intensity and duration. Strike a careful balance between activity and rest. Fear of movement and avoidance of physical activity are common in CFS. Must discuss potential harms of GET with the patient; GET should only be performed in the presence of a trained professional to prevent illness exacerbation.

MEDICATION
There are no established pharmacologic treatments. Medications used are primarily for specific symptoms such as insomnia, mood disorders, and daytime somnolence. If medications are needed, use the lowest effective dose and increase cautiously.

- Studies have been conducted with antivirals, antidepressants, immunoglobulins, hydrocortisone, modafinil, staphylococcus toxoid, methylphenidate, melatonin, and galantamine. None show clear benefit.
- Agomelatine, an antidepressant with agonist activity at melatonin receptors, has been promising in early studies.
- If insomnia is present, use of nonaddicting sleep aids (hydroxyzine, trazodone, doxepin, etc.) may improve outcomes.

ISSUES FOR REFERRAL
- Psychiatrist to manage comorbid behavioral disorders
- Rehabilitative medicine
- Sleep or pain management specialist

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Acupuncture, massage, and chiropractic have been shown to benefit pain for some patients.
- Other helpful nonpharmacologic interventions may include physical therapy, stretches, hydrotherapy, yoga, tai chi, and meditations. Hot or cold packs, warm baths as well as electrical massagers, transcutaneous electrical nerve stimulations can also be considered.
- Equivocal evidence for homeopathy and biofeedback

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Although no consensus exists, periodic reevaluation is appropriate for support, relief of symptoms, and assessment for other possible causes of symptoms.

DIET
- Well-balanced diet, including recommended daily allowance of vitamins and minerals
- No particular diet program has been shown to be effective for treatment of CFS.
- Whether weight loss improves symptoms in obese CFS patients is unknown.

PATIENT EDUCATION
- Gradually increase exercise tolerance.
- Avoid extended periods of rest, but ensure adequate rest between sessions.
- Promote the benefits of cognitive therapies, lifestyle changes, and pharmacologic therapy.
- Chronic Fatigue and Immune Dysfunction Syndrome Association of America: http://solvecfs.org/
- CDC, Chronic Fatigue Syndrome: http://www.cdc.gov/cfs/

PROGNOSIS
- A fluctuating course with relapse is common.
- Improvement is generally slow over months to years.
- An estimated 15% achieve full recovery.
Patients with poor social adjustment, a strong belief in an organic etiology, financial secondary gain, or age >50 years are less likely to improve.

**COMPLICATIONS**

- CFS patients may reduce physical activity out of fear that it may worsen symptoms.
- Depression
- Unemployment: Although studies document improvement with treatment, <1/3rd of patients in trials return to work.
- The Social Security Administration considers CFS to be a disability.
- Receipt of third-party disability pay (secondary gain) has been associated with treatment nonresponse.
- Polypharmacy
- Chronic immune activation or an associated infection may play a role in an increased risk for non-Hodgkin lymphoma in elderly (>80 years) CFS patients.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Fatigue

**CODES**

ICD10

R53.82 Chronic fatigue, unspecified

**CLINICAL PEARLS**

- No pharmacologic agents (e.g., antidepressants, immune modulators) have been shown to be consistently effective in treating CFS.
- There are many more patients with idiopathic chronic fatigue than true CFS.
- Use the IOM criteria to diagnose CFS.
- Standardized instruments (SF-36, symptom index, and Multidimensional Fatigue Inventory
[MFI] help to follow patient progress.
MYASTHENIA GRAVIS
Melody A. Jordahl-Iafrato, MD, FAAFP

BASICS

DESCRIPTION
Primary disorder of neuromuscular transmission characterized by fluctuating muscle weakness:
- Ocular myasthenia gravis (MG) (15%): weakness limited to eyelids and extraocular muscles
- Generalized MG (85%): commonly affects ocular as well as a variable combination of bulbar, proximal limb, and respiratory muscles
- 50% of patients who present with ocular symptoms develop generalized MG within 2 years.
- Onset may be sudden and severe, but it is typically mild and intermittent over many years, maximum severity reached within 3 years for 85%.
- System(s) affected: neurologic, hematologic, lymphatic, immunologic, musculoskeletal

EPIDEMIOLOGY
Occurs at any age but a bimodal distribution to the age of onset:
- Female predominance: 20 to 40 years
- Male predominance: 60 to 80 years

Incidence
Estimated annual incidence 2 to 21/1 million

Prevalence
In the United States, 200/1 million; increasing over the past 5 decades

Pediatric Considerations
A transient form of neonatal MG seen in 10–20% of infants born to mothers with MG. It occurs as a result of the transplacental passage of maternal antibodies that interfere with function of the neuromuscular junction; resolves in weeks to months. Autoimmune juvenile MG makes up 10–15% of cases of MG in North America.

ETIOLOGY AND PATHOPHYSIOLOGY
- Reduction in the function of acetylcholine receptors (AChRs) at muscle end plates, resulting in insufficient neuromuscular transmission
- Antibody-mediated autoimmune disorder
- Antibodies are present in most cases of MG.
  - Seropositive/antiacetylcholine receptor (anti-AChR): a humoral, antibody-mediated, T-cell–dependent attack of the AChRs or receptor-associated proteins at the postsynaptic membrane of the neuromuscular junction. Found in 85% of generalized MG and 50% of ocular MG; thymic abnormalities common (1)
  - Muscle-specific kinase (MuSKs): 5% of generalized MG patients. Typically females. Is a severe form, respiratory and bulbar muscles involved. Thymic abnormalities are rare (1).
  - In remainder of seronegative, 12–50% with anti-LRP4, a molecule that forms a complex with MuSK, mild generalized weakness most common (1)
  - Seronegative MG (SNMG): 5%; may have anti-AChR detectable by cell-based assay.
Clinically similar to anti-AChR; thymic hyperplasia may be present (1).
- Also documented immediately after viral infections (measles, Epstein-Barr virus [EBV], HIV, and human T-lymphotropic virus [HTLV])

**Genetics**
- Congenital MG syndrome describes a collection of rare hereditary disorders. This condition is not immune-mediated but instead results from the mutation of a component of the neuromuscular junction (autosomal recessive).
- Familial predisposition is seen in 5% of cases.

**RISK FACTORS**
- Familial MG
- D-penicillamine (drug-induced MG)
- Other autoimmune diseases

**COMMONLY ASSOCIATED CONDITIONS**
- Thymic hyperplasia (60–70%)
- Thymoma (10–15%)
- Autoimmune thyroid disease (3–8%)

**DIAGNOSIS**
Myasthenia Gravis Foundation of America Clinical Classification (2)[C]:
- Class I: any eye muscle weakness, possible ptosis, no other evidence of muscle weakness elsewhere
- Class II: eye muscle weakness of any severity; mild weakness of other muscles:
  - Class IIa: predominantly limb or axial muscles
  - Class IIb: predominantly bulbar and/or respiratory muscles
- Class III: eye muscle weakness of any severity; moderate weakness of other muscles:
  - Class IIIa: predominantly limb or axial muscles
  - Class IIIb: predominantly bulbar and/or respiratory muscles
- Class IV: eye muscle weakness of any severity; severe weakness of other muscles:
  - Class IVa: predominantly limb or axial muscles
  - Class IVb: predominantly bulbar and/or respiratory muscles (can also include feeding tube without intubation)
- Class V: intubation needed to maintain airway

**HISTORY**
The hallmark of MG is fatigability.
- Fluctuating weakness, often subtle, that worsens during the day and after prolonged use of affected muscles, may improve with rest
- Early symptoms are transient with asymptomatic periods lasting days or weeks.
- With progression, asymptomatic periods shorten, and symptoms fluctuate from mild to severe.
- >50% of patients present with ocular symptoms (ptosis and/or diplopia). Eventually, 90% of patients with MG develop ocular symptoms.
- Ptosis might be unilateral, bilateral, or shifting from eye to eye.
- 15% present with bulbar symptoms.
<5% present with proximal limb weakness alone.

**ALERT**
Myasthenic crisis: respiratory muscle weakness producing respiratory insufficiency and pending respiratory failure

**PHYSICAL EXAM**
- Ptosis may worsen with propping of opposite eyelid (curtain sign) or sustained upward gaze.
- "Myasthenic sneer," in which the midlip rises but corners of mouth do not move
- Muscle weakness is usually proximal and symmetric.
- Test for muscle fatigability by repetitive or prolonged use of individual muscles.
- Important to test and monitor respiratory function

**DIFFERENTIAL DIAGNOSIS**
- Thyroid ophthalmopathy
- Oculopharyngeal muscular dystrophy
- Myotonic dystrophy
- Kearns-Sayre syndrome
- Chronic progressive external ophthalmoplegia
- Brainstem and motor cranial nerve lesions
- Botulism
- Motor neuron disease (e.g., amyotrophic lateral sclerosis [ALS])
- Lambert-Eaton myasthenic syndrome
- Drug-induced myasthenia
- Congenital myasthenic syndrome
- Dermatomyositis/polymyositis
- Neurosarcoidosis
- Tolosa-Hunt syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Anti-AChR antibody (74–85% are seropositive):
  - Generalized myasthenia: 75–85%
  - Ocular myasthenia: 50%
  - MG and thymoma: 98–100%
  - Poor correlation between antibody titer and disease severity (1)[C]
  - False-positive results in thymoma without MG, Lambert-Eaton myasthenic syndrome, small cell lung cancer, and rheumatoid arthritis treated with penicillamine
- Anti-MuSK antibody:
  - Used if MG is suspected, patient seronegative
  - Strong correlation between titer and disease severity (1)[C]
- LRP4 and clustered anti-AChR:
  - Used if MG suspected, patient seronegative
- Thyroid and other autoimmune testing antistriated muscle (anti-SM) antibody:
  - Present in 84% of patients with thymoma who are <40 years of age
  - Can be present without thymoma in patients >40 years of age
- Chest radiographs or CT scans may identify a thymoma.
- MRI of brain and orbits to rule out other causes of cranial nerve deficit

### Diagnostic Procedures/Other

- **Tensilon (edrophonium) test:**
  - Initial 2-mg IV dose, followed by another 2 mg every 60 seconds up to a maximum dose of 10 mg
  - A positive test shows improvement of strength within 30 seconds of administration.
  - Sensitivity 80–90% (3)[C]
  - Cardiac disease and bronchial asthma are relative contraindications, especially in elderly.
  - Atropine: 0.4 to 0.6 mg IV may rarely be required as antidote; must be available
  - Can also do trial of other cholinesterase inhibitors (neostigmine or oral) and monitor response

- **Ice pack test:**
  - Ice pack applied to closed eyelid for 60 seconds, then removed; extent of ptosis immediately assessed
  - Ice will decrease the ptosis induced by MG.
  - Sensitivity 80% in patients with prominent ptosis

- **Electrophysiology testing:**
  - Repetitive nerve stimulation (RNS):
    - Widely available, most frequently used
    - Moderately sensitive for both generalized MG (75%) and ocular MG (50%) (3)[C]
  - Single-fiber electromyogram (SFEMG):
    - Assesses temporal variability between two muscle fibers within same motor unit (jitter)
    - Sensitive (90–95%) but less specific
    - Technically difficult to perform; limited availability, use if suspected and negative RNS (3)[C]

### Test Interpretation

- Lymphofollicular hyperplasia of thymic medulla occurs in 65% of patients with MG, thymoma in 15%.
- Immunofluorescence: IgG antibodies and complement on receptor membranes in seropositive patients

### TREATMENT

#### GENERAL MEASURES

- Treatment based on age, gender, and disease severity and progression
- Three basic approaches: symptomatic, immunosuppressive, and supportive. Few should receive a single therapeutic modality.

#### MEDICATION

### First Line

Symptomatic treatments (anticholinesterase agents)

- Pyridostigmine bromide (Mestinon):
  - Most commonly prescribed because available in oral tablet
  - Starting dose of 30 mg PO TID with food
- Maximum dose: 120 mg q3–4h
- Long acting available but effect not consistent

**Neostigmine methylsulfate (Prostigmin):**
- Starting dose of 0.5 mg SC or IM q3h
- Titrate dosage to clinical need.

**Patients with anti-MuSK may not respond well to these medications.**

### Second Line

- **Immunosuppressants:** Oral corticosteroids are the first choice of drugs when immunosuppression is necessary.
  - **Prednisone:** Start as inpatient with a 60 mg/day PO; taper the dosage every 3 days; switch to alternate-day regimen within 2 weeks. Taper very slowly to establish the minimum dosage necessary to maintain remission (4)[B].
  - **Cyclophosphamide:** adults: 1 to 5 mg/kg/day PO; children: 2 to 8 mg/kg/day PO (4)[B]
  - **Cyclosporine:** adults: 5 mg/kg/day PO (nephrotoxicity and drug interactions) (4)[B]
  - **Mycophenolate:** 1 g PO or IV BID
  - **Azathioprine:** 100 to 200 mg/day PO (4)[B]
    - Most frequently used for long-term immunomodulation, similar efficacy to steroids and IVIG
    - Benefit may not be apparent for up to 18 months after initiation of therapy.
    - Prednisolone + azathioprine may be effective when used as a corticosteroid-sparing agent.

- **Acute immunomodulating treatments:**
  - **Plasmapheresis:** bulk removal of 2 to 3 L of plasma 3 times per week, repeated until rate of improvement plateaus (5)[B]
    - Improves weakness in nearly all and can last up to 3 months
  - **Immunoglobulin:** 2 g/kg IV over 2 to 5 days (4)[B]
    - Plasmapheresis and immunoglobulin have comparable efficacy in treating moderate to severe MG (5)[C].
    - Rapid onset of effect but short duration of action
    - Used for acute worsening of MG to improve strength prior to surgery, prevent acute exacerbations induced by corticosteroids, and as a chronic intermittent treatment to provide relief in refractory MG

- **Other immunosuppressant therapies:**
  - **Tacrolimus**
  - **Rituximab:** Seronegative MuSK-antibody positive MG patients may have better response to rituximab than conventional therapies.

### ALERT

Use caution with drugs that can precipitate weakness: aminoglycosides, fluoroquinolones, β-blockers, calcium channel blockers, neuromuscular blockers, statins, diuretics, oral contraceptives, gabapentin, phenytoin, lithium, among others.

### SURGERY/OTHER PROCEDURES

- Thymectomy recommended for patients with thymic abnormalities
- May be beneficial for patients without thymic abnormalities in those <60 years of age especially in patients with elevated anti-AChR
**Pediatric Considerations**

Infants with severe weakness from transient neonatal myasthenia may be treated with oral pyridostigmine; general support is necessary until the condition clears.

- Corticosteroids limited only to severe disease
- Side effects of many medications must be closely monitored in juvenile patients especially because some may affect long-term fertility or are consider carcinogenic.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Management of pulmonary infections
- Myasthenic/cholinergic crises
- Plasmapheresis
- IV γ-globulin

**ONGOING CARE**

**PATIENT EDUCATION**

**PROGNOSIS**

- Overall good but highly variable
- Myasthenic crisis associated with substantial morbidity and 4% mortality
- Seronegative patients are more likely to have purely ocular disease, and those with generalized SNMG have a better outcome after treatment.

**COMPLICATIONS**

Acute respiratory arrest; chronic respiratory insufficiency

**REFERENCES**

**ADDITIONAL READING**

- Meriggioli MN. Myasthenia gravis: immunopathogenesis, diagnosis, and management.
CODES

ICD10
- G70.00 Myasthenia gravis without (acute) exacerbation
- G70.01 Myasthenia gravis with (acute) exacerbation
- P94.0 Transient neonatal myasthenia gravis

CLINICAL PEARLS
- An autoimmune disease, marked by abnormal fatigability and weakness of selected muscles, which is relieved by rest
- Anticholinesterase medication and a thymectomy lessen symptom severity.
- Steroid therapy, plasma exchange, or immunoglobulin can be used in severely affected patients.
Myelodysplastic Syndromes (MDS)
Gabriela Sanchez-Petitto, MD • Pedro Emilio Alcedo, MD Guillermo Garcia-Manero, MD

BASICS

DESCRIPTION
- Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal stem cell disorders characterized by peripheral blood cytopenias: anemia, thrombocytopenia, and/or neutropenia.
- Dysplasia refers to an abnormality of development or differentiation in specific cell lines. In MDS, these changes take place in the bone marrow and confer a tendency for leukemic transformation.

EPIDEMIOLOGY

Incidence
The incidence in the United States is approximately 3 to 4 cases per 100,000 population per year, expanding to 30 cases per 100,000 population per year, for patients age >70 years.

Prevalence
In 2012, >60,000 people with MDS resided in the country.

ETIOLOGY AND PATHOPHYSIOLOGY
- MDS is clinically characterized by peripheral cytopenias, consequence of ineffective marrow hematopoiesis (premature cell death).
- Nongenetic mechanisms encompass apoptosis, pyroptosis, deregulated immunity, and inflammatory cytokine amplification (see “Genetics” for genetic mechanisms) (1,2).
- Low-risk MDS (LR-MDS) are characterized by deregulated immunity and apoptosis, whereas high-risk MDS (HR-MDS) are characterized by clonal expansion and transformation to acute myelogenous leukemia (AML).
- A changing interplay of proapoptotic versus antiapoptotic signals is central in the progression of the disease.
- In LR-MDS, stem cell programmed death occurs by different mechanisms: apoptosis, pyroptosis, and potentially autophagy.
  - Apoptosis: Tumor necrosis factor (TNF)-α, TNF-related apoptosis-inducing ligand (TRAIL), Fas ligand, and proapoptotic cytokines (TNF-α and IL-6) play a major role in stem cell apoptosis in LR-MDS.
  - Pyroptosis: It is an inflammatory cell death different from apoptosis that is considered sterile in nature.
    o Activation of nod-like receptors leads to formation of the inflammasome complex and caspase 1 activation that leads to pore formation in the plasma membrane of the cells; creates ionic gradients, water influx, cell swelling, and cell death (3)
    o This potentially also explains the morphologic changes seen in MDS (macrocytosis, enlarged cells).
- Evolution to AML has been associated with upregulation of NFκB, enhanced activity of the Bcl2 and the inhibitors of apoptosis protein (IAP) families.
– This is thought to be a mechanism of bypassing the apoptotic phenomenon in the bone marrow microenvironment.

**Genetics**
- Recurrent somatic mutations are observed in >90% of MDS patients.
- Mutated genes are involved in:
  - Epigenetic regulation: TET2, EZH2, IDH1, IDH2, DNMT3A, ASXL1
  - DNA repair: TP53
  - Transcriptional regulation: BCOR, ETV6, RUNX1
  - RNA splicing: U2AF35, ZRSR2, SF3B1, SRSF2
  - Cohesin complex: STAG2
  - Signal transduction: JAK2, CBL, NRAS
- Mutations in the epigenetic modifiers: The concept is that any gain of function mutations in the DNA methyltransferases (DNMT3A and DNMT3B) leads to hypermethylation (a gene silencing mechanism that contributes to clonal evolution).
- It is unclear how these different molecular and genetic mechanisms translate into the same phenotypic manifestation of myelodysplasia and cytopenias.

**RISK FACTORS**
- Age: increased risk in patients >60 years old
- Tobacco use
- Chronic exposure to chemicals: benzene, pesticides, insecticides, and petroleum
- Prior chemotherapy or radiation therapy
- Inherited disorders: Fanconi anemia, Shwachman-Diamond syndromes, severe congenital neutropenia, and familial platelet disorder

**GENERAL PREVENTION**
Avoiding known cancer-causing industrial chemicals, such as benzene, and also tobacco, might lower the risk of developing MDS.

**COMMONLY ASSOCIATED CONDITIONS**
Myeloproliferative disorders and paroxysmal nocturnal hemoglobinuria

**DIAGNOSIS**

**HISTORY**
- The clinical course of MDS patients is driven by the type and degree of cytopenias.
- Recurrent infections, bleeding issues, fatigue, weight loss and exertional dyspnea, are common symptoms reported.

**PHYSICAL EXAM**
- Generalized pallor and ecchymosis as result of the anemia and thrombocytopenia respectively
- Rarely hepatosplenomegaly as consequence of extramedullary hemopoiesis is present, especially in MDS/MPN overlapping syndromes. Lymphadenopathies are infrequent.

**DIFFERENTIAL DIAGNOSIS**
- Acute leukemia: AML
Vitamin B₁₂ and folate deficiencies can manifest as a hypoproliferative anemia.

Infections of the bone marrow: human immunodeficiency virus, tuberculosis, atypical mycobacterium and Epstein-Barr virus

Indolent myeloid hematopoietic disorders that do not fulfill diagnostic criteria for MDS: idiopathic cytopenia of unknown significance, idiopathic dysplasia of unknown significance, clonal hematopoiesis of indeterminate potential (CHIP), and clonal cytopenia of unknown significance

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- A complete blood count, chemistry, viral studies (HIV and hepatitis panel), and vitamin levels (B₁₂ and folate) should be evaluated.
- The International Working Group (IWG) recommended minimal diagnostic prerequisites:
  - Stable cytopenia for ≥6 months or for 2 months with karyotype or bilineage dysplasia
  - Exclusion of other potential reasons for dysplasia/cytopenia
- In addition, the diagnosis of MDS requires ≥1 of 3 decisive criteria:
  - Dysplasia (≥10% in ≥1 of the 3 major bone marrow lineages)
  - Blast cell count of 5–19%
  - Specific MDS-associated karyotypes: del(5q), del(20q), +8, or −7/del(7q)

**Diagnostic Procedures/Other**
- Histopathology. A bone marrow is essential to distinguish MDS from AML and to perform karyotype studies, fluorescent in situ hybridization (FISH), and mutational studies.
  - Blast %: <20% is consistent with MDS; ≥20% is diagnostic of AML.
- Cytogenetics. Clonal chromosome abnormalities are observed in 30–80% of MDS patients. In the rest of the patients (20–70%), submicroscopic alterations (microdeletions, point mutations) provide diagnostic evidence.
- In cases of uncertainty, analysis of somatic mutations and flow cytometry of bone marrow can evidence clonal disease.

**Test Interpretation**
- Hematologic findings in the blood smear include macrocytic anemia, hyposegmented neutrophils (pseudo Pelger-Huet), and thrombocytopenia.
- A low reticulocyte index reflects the hypoproliferative nature of the disease.

**TREATMENT**

**GENERAL MEASURES**
- LR-MDS: observation until patients develop symptoms from anemia, neutropenia, and/or thrombocytopenia
  - Initial treatment is tailored based on the specific cytopenia.
- In higher risk, the only curative therapy is allogeneic stem cell transplant (SCT).
- An accurate assessment of prognosis becomes critical for therapeutic decision making. For this aim, multiple scoring system have been developed:
  - The World Health Organization (WHO) guidelines identify six entities: MDS with single lineage dysplasia; MDS with ring sideroblasts; MDS with excess blasts; MDS with
multilineage dysplasia; MDS with isolated del(5q); and MDS unclassifiable.

– The International Prognostic Scoring System (IPSS) score assigns patients to four groups (low, intermediate 1, intermediate 2, high) on the basis of number of cytopenias, karyotype, and blast percentage in the bone marrow.

– The MDAS (Global MD Anderson) score refines prognostic precision as complementary to the IPSS.

MEDICATION

First Line

● MDS-related anemia
  – Blood transfusions and erythropoiesis-stimulating agents (ESA)
    o ESA have a 40–50% response rate in LR-MDS; indications: hemoglobin <10 g/dL and erythropoietin level <500; uncommon complications: worsening hypertension and thromboembolism
  – Lenalidomide; used in anemia in MDS with isolated del(5q) (4); acts via casein kinase, inhibiting the nuclear β-catenin accumulation, subsequently restoring normal erythropoiesis

● MDS-related thrombocytopenia and neutropenia
  – In selected cases, thrombopoietin receptor agonists (romiplostim, eltrombopag) may be used for thrombocytopenia (with close monitoring owing its potential for leukemic transformation). Neutropenia may be managed with G-CSF and antibiotics, if clinically indicated.

● Low-intensity chemotherapy
  – In LR-MDS patients who lost response to the first line, the use of hypomethylating agents (HMA) is approved by the Food and Drug administration.
    o HMA are disease-modifying agents. Examples are azacitidine and decitabine.
    o HMA cause DNA hypomethylation via DNMT1 sequestration.

● High-intensity chemotherapy
  – Induction chemotherapy or SCT
    o Comparative studies have not demonstrated benefit between different intensive chemotherapy regimens (cytarabine, idarubicin, topotecan-based regimens) (5).

● SCT
  – To date, allogenic SCT remains the only curative treatment option but is reserved for high-risk disease due to its owned toxicity.
    o Patients <70 years of age with an available donor and reasonable comorbidity should be considered.
    o Mortality after the procedure is attributable to transplant-related complication or relapse.

Second Line

There are not well-established agents as second-line treatment. Clinical trials can be considered for patients depending on their severity (low vs. high risk), cytopenias, and potential for transplantation.

ISSUES FOR REFERRAL

● Patients with cytopenias should be evaluated by a hematologist–oncologist.
● Evaluation of bone marrow with a hemopathologist is recommended.
● Referral to a bone marrow transplant team should be done if patient is a candidate for SCT.

ADDITIONAL THERAPIES
Management of iron overload. Iron chelation is often considered in patients with transfusion dependency.

Promising agents. Clinical trials with novel HMA (SGI-110, E7727), ABT 199, drugs targeting the TGF-β/SMAD sign and toll-like receptor pathways are currently ongoing.

SURGERY/OTHER PROCEDURES
Allogenic SCT, as discussed previously

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Complications such as bleeding, neutropenic fever, and undergoing SCT, warrant a hospital admission.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow-up of MDS is based on regular complete blood counts to detect the need for transfusions. Severe neutropenia may indicate antibiotic use if infection occurs.
- Bone marrow examination is generally triggered by worsening of cytopenias.

DIET
Alcohol consumption, meat, vegetable, and fruit intake do not appear to have significant influence in the risk of developing disease.

PATIENT EDUCATION
- Regular follow-up and compliance with medications; smoking cessation
- Instruct about symptoms that should prompt the patient to receive blood transfusion or commence antibiotics.

PROGNOSIS
Overall, the outcome of MDS patients is variable, with median survival ranging from 6 months to >5 years.

COMPLICATIONS
Infection and bleeding are the leading causes of death, rather than AML conversion.

REFERENCES
CODES

ICD10
- D46.9 Myelodysplastic syndrome, unspecified
- D46.4 Refractory anemia, unspecified
- D46.B Refract cytopenia w multilin dysplasia and ring sideroblasts

CLINICAL PEARLS
- MDS are a heterogeneous group of clonal stem cell disorders characterized by blood cytopenias and tendency for leukemic transformation.
- Different molecular and genetic mechanisms of pathogenesis translate into the same phenotypic manifestation of the disease.
- Infection and bleeding are the leading causes of death.
- SCT is ultimately the only curative treatment.
BASICS

DESCRIPTION
- Myeloproliferative neoplasms (MPNs) are a group of clonal disorders that share a common cell of origin in the pluripotent hematopoietic stem cell.
- MPNs are characterized by proliferation of cells of myeloid lineage—granulocytic, erythroid, megakaryocytic, or mast cell. They share common clinical features including risk of thrombosis, spleen and/or liver enlargement, and constitutional symptoms related to a hypermetabolic state.
- The “classic” MPNs include chronic myelogenous leukemia (CML), polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). World Health Organization (WHO) MPN classification also includes chronic neutrophilic leukemia, chronic eosinophilic leukemia not otherwise specified (CEL-NOS), systemic mastocytosis, and MPN unclassifiable.
- This topic focuses on the classic MPNs.
- CML is characterized by the presence of Philadelphia chromosome (reciprocal translocation between chromosomes 9 and 22 resulting in a BCR-ABL fusion gene). This fusion gene mediates the uninhibited proliferation of myeloid precursor stem cells predominantly resulting in granulocytosis and excess granulocyte precursors.
- The following three MPNs are characterized by varying degree of presence of JAK2 V617F mutation and are negative for BCR-ABL fusion gene:
  - PMF: JAK2 in about 50%; MPN characterized by marrow fibrosis, extramedullary hematopoiesis, and splenomegaly
  - ET: JAK2 in about 50%; MPN characterized by a clonal proliferation of megakaryocytes, leading to thrombocytosis
  - PV: JAK2 in 95%; MPN characterized by trilineage growth of hematopoietic stem cells with erythroid precursors predominating, leading to erythrocytosis

EPIDEMIOLOGY

Incidence
- CML: 0.6 to 2.0/100,000/year; median age at diagnosis 66 years; male > female (1.6:1)
- PMF: 0.2 to 0.5/100,000/year; median age at diagnosis 65 years; male = female
- ET: 0.6 to 2.5/100,000/year; median age at diagnosis 60 years, second peak in younger patients at ~30 years; female > male (2:1)
- PV: 1 to 2/100,000/year; male > female (1.3:1)

ETIOLOGY AND PATHOPHYSIOLOGY
- CML: BCR-ABL1 gene leads to increased and unrestrained activity of the ABL tyrosine kinase resulting in an unchecked activation of downstream signaling pathways which have an antiapoptotic effect on the hematopoietic cells.
- PMF: Progenitor hematopoietic stem cells undergo a clonal proliferation independent of
growth factors likely due to activation of downstream intracellular pathways. The fibroblasts are nonclonal, and the increased fibrosis is driven by growth factors released by hematopoietic cells especially megakaryocytes.

- ET: Thrombopoietin-induced megakaryocyte proliferation is uncontrolled due to a combination of increased sensitivity to thrombopoietin and decreased feedback regulation of the thrombopoietin levels by platelets allowing the platelet mass to expand.
- PV: Gain-of-function mutation (JAK2) leads to increased erythrocyte production due to a downstream activation of proteins involved in cell proliferation and resistance to apoptosis. The JAK2 tyrosine kinase is downstream of the erythropoietin receptor and thus its constitutive activation makes the hematopoietic progenitor cell independent of erythropoietin.

**Genetics**

- In >95% of MPNs, mutations driving the phenotype are on three genes: JAK2, calreticulin (CALR), and MPL; mutation occurring mutually exclusive manner
- Philadelphia chromosome (BCR-ABL1 gene): translocation and fusion of the BCR gene on chromosome 22 and the ABL gene on chromosome 9; seen in all patients with CML
- JAK2 mutations: gain-of-function point mutations in the tyrosine kinase domain of JAK2, causing a substitution of phenylalanine for valine at position 617 (JAK2 V617F), leading to unrestrained JAK2 activation with a deactivation of typical feedback mechanism. Seen in >95% of PV cases; 50% of ET and PMF cases
- CALR frameshift mutation: CALR is an endoplasmic reticulum chaperone protein directing proper folding of proteins. This mutation may be seen in up to a third of patients of ET and PMF. These patients are seen to have a higher platelet count but lower risk of thrombosis.
- Myeloproliferative leukemia virus (MPL) gene: gain-of-function point mutations found in 5–10% of patients with PMF and in 3–5% of those with ET. This encodes the thrombopoietin receptor MPL.

**RISK FACTORS**

- Rare familial cases have been reported.
- CML: exposure to ionizing radiation

**COMMONLY ASSOCIATED CONDITIONS**

- Progression to acute myeloid leukemia; most common with CML
- Thrombosis/hemorrhage

**DIAGNOSIS**

**HISTORY**

- Many MPN cases are found incidentally on routine blood work.
- CML: 20–50% of patients are asymptomatic at time of diagnosis.
  - Fatigue, malaise, weight loss, excessive perspiration, abdominal fullness, early satiety, bleeding episodes, LUQ pain, acute gouty arthritis
- PMF: Symptoms depend on the degree of anemia and splenomegaly.
  - Severe fatigue, dyspnea, early satiety, pruritus, constitutional symptoms, cachexia, Budd-Chiari syndrome, splenic infarcts, osteosclerosis resulting in bone pains
- ET: characterized by thrombotic and hemorrhagic events. 50% are asymptomatic.
  - Vasomotor symptoms: headache, light-headedness, syncope, atypical chest pain,
erythromelalgia (burning pain of the hands or feet with erythema and warmth), transient visual disturbances (amaurosis fugax, scintillating scotomata)

- Thrombotic events: deep vein thrombosis, pulmonary embolism, Budd-Chiari syndrome digital ischemia, transient ischemic attack, stroke, retinal artery or venous occlusion, coronary artery ischemia; major/minor hemorrhagic events
- Pregnancy loss

- PV: Symptoms are due to level of erythrocytosis and the resultant increased blood viscosity.
  - Erythromelalgia, pruritus after hot baths, facial plethora, headaches, tinnitus, paresthesias, gout attacks

PHYSICAL EXAM

- CML: splenomegaly, hepatomegaly
- PMF: marked splenomegaly seen in >90% of patients, hepatomegaly, pallor
- ET: petechiae, purpura, ecchymosis; splenomegaly
- PV: cyanotic blush (lips, nose, ears, distal extremities), increased blood pressure, splenomegaly, epistaxis, ecchymosis, skin excoriation

DIFFERENTIAL DIAGNOSIS

- CML: leukemoid reaction (high LAP score, lack of myelocyte bulge), juvenile myelomonocytic leukemia, chronic myelomonocytic leukemia (CMML), chronic eosinophilic leukemia, chronic neutrophilic leukemia. Philadelphia chromosome is also positive in 20–30% B-ALL and few cases of acute myeloid leukemia.
- PMF: other MPNs, lymphoma, hairy cell leukemia; secondary myelofibrosis (malignant or nonmalignant)
- ET: reactive thrombocytosis, CML, PV, PMF, and myelodysplastic syndromes
- PV: hypoxic states (e.g., chronic obstructive pulmonary disease [COPD], anemia), renal cell carcinoma, Wilms tumor, hepatoma, polycystic kidney disease, exogenous androgens

DIAGNOSTIC TESTS & INTERPRETATION

- CML: white blood cell (WBC) count >10,000 × 10^9/L with differential showing increased mature and immature neutrophils and an increased percentage of myelocytes, metamyelocytes, and band forms; absolute basophilia is seen in all cases and absolute eosinophilia in >90% of cases. Neutrophils have decreased leukocyte alkaline phosphatase; platelet count >600,000 × 10^9/L and a normochromic, normocytic anemia
- PMF (1)[A] (WHO criteria): Diagnosis requires meeting all three major criteria and two or more minor criteria:
  - Major criteria: (i) megakaryocyte proliferation and atypia accompanied by either reticulin or collagen fibrosis; (ii) not meeting WHO criteria for CML, PV, MDS, or other myeloid neoplasm; (iii) demonstration of JAK2 V617F or other clonal marker or absence of marker with no evidence of secondary marrow fibrosis
  - Minor criteria: (i) leukoerythroblastosis, (ii) increased serum lactate dehydrogenase level, (iii) anemia, and (iv) palpable splenomegaly
- ET (1)[A] (WHO criteria): Diagnosis requires meeting all four major criteria:
  - Major criteria: (i) thrombocytosis with persistent platelet level ≥450 × 10^9/L; (ii) megakaryocyte proliferation with large and mature morphology; (iii) not meeting the WHO criteria for CML, PV, PMF, MDS, or other myeloid neoplasm; and (iv) demonstration of JAK2 V617F or other clonal marker or absence of clonal marker with no evidence of
reactive thrombocytosis

- **PV** (1)(A) (WHO criteria): Diagnosis requires either both major criteria and one minor
criterion or the first major criterion and two of the minor criteria:
  - Major criteria: (i) hemoglobin >18.5 g/dL in men, >16.5 g/dL in women, or other evidence
    of increased red cell volume and (ii) presence of JAK2 V617F or other functionally similar
    mutation (e.g., JAK2 exon 12 mutation) (1)(B)
  - Minor criteria: (i) bone marrow biopsy showing hypercellularity for age with trilineage
    myeloproliferation, (ii) low serum erythropoietin level, (iii) endogenous erythroid colony
    formation in vitro

**Initial Tests (lab, imaging)**

If clinical suspicion of MPN, obtain a CBC and peripheral blood smear; if suggestive, obtain
bone marrow biopsy.

- **PMF**: radiographic osteosclerosis in 25–66%

**Diagnostic Procedures/Other**

- **CML**: diagnosis with identification of Philadelphia chromosome: Fluorescence in situ
  hybridization is more sensitive than karyotyping and is routinely used. Polymerase chain
  reaction (P210) is done at baseline to help monitor response to tyrosine kinase inhibitors
  (TKIs).
  - Bone marrow biopsy: increased cellularity and increased myeloid to erythroid ratio
- **PMF, ET, and PV**: genotypic analysis and bone marrow biopsy as described in earlier WHO
  criteria; “dry tap” is common in PMF.
- **Risk stratification**
  - **CML**: three phases
    - (i) Chronic phase (85% patients at diagnosis; <5% blast counts)
    - (ii) Accelerated phase (poorly controlled splenomegaly regardless of treatment, 10–19%
      blast counts, worsening anemia, basophil ≥20%)
    - (iii) Blast crisis (resembles acute myeloid or lymphoid leukemia, >20% blast counts)
  - **PMF**: International Prognostic Scoring System (IPSS) at diagnosis and Dynamic IPSS
    (DIPSS-plus) throughout disease
    - IPSS: age >65 years, constitutional symptoms, hemoglobin <10 g/dL, leukocyte count
      >25 × 10⁹/L, circulating blasts >1%
      - Low risk = 0 of above, intermediate-1 risk = 1 of above, intermediate-2 risk = 2 of
        above, high risk = ≥3 of above
    - DIPSS-plus: same five risk factors in the IPSS + need for red cell transfusion, platelets
      <100 × 10⁹/L, and unfavorable karyotype
      - Low risk = 0 of above, intermediate-1 risk = 1 of above, intermediate-2 risk = 2 to 3
        of above, high risk = ≥4 of above
  - **ET**: low risk = age <40 years, no prior thromboembolic events, no cardiovascular risk
    factors, platelet count <1,500 × 10⁹/L; intermediate risk = age 40 to 59 years, presence of
    cardiovascular risk factors, platelet count <1,500 × 10⁹/L; high risk = age ≥60 years and/or
    prior thromboembolic or hemorrhagic episode and/or platelet count >1,500 × 10⁹/L
  - **IPSET score** includes presence of JAK-2 mutation to these conventional risk factors.
  - **PV**: low risk = age <60 years, no history of thrombosis/cardiovascular risk factors;
    intermediate risk = platelets >1,000 × 10⁹/L and cardiovascular risk factors; high risk = age
>60 years or a history of thrombosis

**TREATMENT**

**GENERAL MEASURES**
Low-dose aspirin for ET and PV

**MEDICATION**

**First Line**
- CML: TKIs are mainstay of treatment.
  - Chronic phase: imatinib mesylate (Gleevec): 400 mg/day is the safest choice.
- Other options: dasatinib (avoid in GI bleed), nilotinib (avoid in CHF and prolonged QT interval), or bosutinib. Accelerated or blast phase: Increase imatinib to 800 mg/day or switch to nilotinib or dasatinib.
  - While awaiting confirmation of diagnosis, hydroxyurea can be used to lower the WBC count.
  - Numerous studies show 40–50% patients have durable molecular response, and TKI can be discontinued at that point.
- PMF: Main goal is symptomatic relief:
  - Low risk: symptom-directed therapy
  - Intermediate and high risk: Consider allogeneic SCT (aSCT).
  - JAK2 inhibitor ruxolitinib is approved for intermediate or high-risk myelofibrosis. It is also approved for post-PV and post-ET myelofibrosis (2).
  - Supportive treatment
    - Anemia: transfusions, erythropoiesis-stimulating agents, androgens, danazol, thalidomide, lenalidomide, or splenectomy
    - Splenomegaly: ruxolitinib, hydroxyurea, splenectomy, splenic radiation, or IV cladribine for refractory cases
    - Thrombosis: hydroxyurea and low-dose aspirin
    - Blast phase PMF: cytoreduction and transplant if eligible
- ET: in low and intermediate risk: “Watch and wait” + low-dose aspirin if microvascular disturbances are present and no contraindications. In high risk: hydroxyurea 15 mg/kg/day in divided doses to reduce platelet count to <450 × 10^9/L (2). Anagrelide is an additional cytoreductive option.
- PV
  - Low and intermediate risk: phlebotomy with goal hematocrit <45% and low-dose aspirin
  - High risk (or those who do not tolerate phlebotomy): hydroxyurea 500 to 1,000 mg/day (2); ruxolitinib if poor response to or intolerance of hydroxyurea

**Second Line**
- CML: Only curable treatment is aSCT; reserved for accelerated/blast phase due to high rates of morbidity and mortality with aSCT
  - 2nd-generation TKIs: dasatinib, nilotinib, and bosutinib; increasing evidence for improved, deeper responses with these medications resulting in use of 2nd-generation TKIs for first-line therapy. Ponatinib is a 3rd-generation TKI that has activity in cases of TKI resistance due to a T315I mutation for which all the other available TKIs are ineffective. Sokal score
can be used to predict achievement of molecular response and survival outcomes; patients with higher Sokal score may perform better with 2nd-generation TKIs.

- PMF: Only curable treatment is aSCT; reserved for intermediate- or high-risk patients
  - If unresponsive to hydroxyurea, use pegylated interferon-α; tolerance may be an issue.
- ET: If resistant/intolerant to hydroxyurea, use anagrelide.
  - If resistant/intolerant to hydroxyurea or anagrelide, pregnant, or age <40 years, use interferon-α.
- PV: if resistant or intolerant to hydroxyurea, can use ruxolitinib

**ISSUES FOR REFERRAL**

Patients with MPNs are usually referred to hematology/oncology.

**SURGERY/OTHER PROCEDURES**

- May require splenectomy/palliative radiation for foci of extramedullary hematopoiesis
- Hematopoietic stem cell transplant if eligible

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Severe cachexia; renal failure and hepatomegaly secondary to extramedullary hematopoiesis; massive splenomegaly requiring treatment; severe thrombotic/hemorrhagic episodes; anemia; tumor lysis syndrome
- Optimal hydration to prevent tumor lysis syndrome

**ONGOING CARE**

**PROGNOSIS**

- CML: 10-year survival rate ~80% from time of diagnosis; 85% will die in blast crisis; 12- to 18-month median survival for accelerated phase; 3- to 6-month median survival for blast phase
- PMF: worst prognosis of the MPNs; drug therapy does not modify disease course but treats the symptoms; median survival for IPSS low risk = 135 months, intermediate-1 risk = 95 months, intermediate-2 risk = 48 months, high risk = 27 months
- PV: median survival often >10 years
- ET: near-normal life expectancy

**COMPLICATIONS**

- CML: blast crisis, transformation to acute leukemia, gout, or nephropathy due to hyperuricemia
- PMF: 10% develop acute myeloid leukemia; anemia, massive hepatosplenomegaly, thrombohemorrhagic events, osteosclerosis, secondary gout, splenic infarcts, paraspinal/epidural extramedullary hematopoiesis
- ET: <10% develop post-ET myelofibrosis, 2% develop acute myeloid leukemia; thrombohemorrhagic events
- PV: 15–20% develop post-PV myelofibrosis, 5% develop leukemia; erythromelalgia, pruritus, secondary gout, headaches, vascular occlusive events

Leukemia, Chronic Myelogenous; Polycythemia Vera

CODES

ICD10
• D47.1 Chronic myeloproliferative disease
• C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
• D45 Polycythemia vera

CLINICAL PEARLS

• MPNs are a group of clonal disorders that share a common cell of origin in the pluripotent hematopoietic stem cell.
• MPNs are characterized by proliferation of cells of myeloid lineage—granulocytic, erythroid, megakaryocytic, or mast cell. They share common clinical features including risk of thrombosis, spleen and/or liver enlargement, and constitutional symptoms related to a hypermetabolic state.
• Splenectomy as an option for symptom and cytopenia control is associated with high risk of postsplenectomy mortality and complications including thrombosis.
**NARCOLEPSY**
Waiz Wasey, MD • Taaha S. Rafi, MD

---

**BASICS**

**DESCRIPTION**
- Narcolepsy is a chronic incurable neurologic sleep disorder mainly characterized by excessive daytime sleepiness (EDS) and may be associated with cataplexy (sudden loss of muscle control), hypnagogic hallucinations (vivid perceptual experiences while falling asleep), hypnopompic (vivid perceptual experiences while waking up from sleep), or sleep paralysis (temporary inability to move or speak that happens during transition from sleeping to awake state).
- Mainly two types identified by American Academy of Sleep Medicine:
  - Type 1 (60–70%) (formerly narcolepsy with cataplexy) and type 2 (formerly narcolepsy without cataplexy) (1)
- Usually diagnosed 5 to 15 years after the onset of symptoms
- No cure, symptomatic management

**EPIDEMIOLOGY**

**Incidence**
- Affects 0.03 to 0.16% general population with incidence 1/2,000 worldwide (2)
- Bimodal distribution, age of onset peak at 15 years and again at 35 years of age
- Predominant sex: male > female (1.6:1)
- 5% familial cases (1)
- African Americans are more likely to present without cataplexy and at a younger age.

**Prevalence**
- Narcolepsy type 1: 25 to 50/100,000 people
- Narcolepsy type 2: 20 to 34/100,000 people (1)
- Highest in Japan, lowest in Israel

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Primarily caused by degeneration of hypothalamic neurons that produce orexin (hypocretin). Postmortem studies show 85% loss of these neurons in type 1 and about 33% loss in type 2 (1).
- Orexin is crucial to promote wakefulness, it stimulates the RAS (reticular activating system) and inhibits rapid eye movement.
- Neurodegeneration may be caused by autoimmune process, probably stimulated by infections (such as influenza A or Group A Streptococcus) or environmental factors (occurs commonly in late spring).
- Alterations in the L-PGDS (lipocalin-type prostaglandin D synthase) level also seem to be involved in causing EDS in narcolepsy (1).
- International Classification of Sleep Disorders 3rd edition (ICSD-3) classification:
  - Narcolepsy
  - Narcolepsy type 1
  - Narcolepsy type 2
– Narcolepsy due to medical conditions

**Genetics**
- Usually sporadic but increased incidence in families with positive history: 1–2% in first-degree relative of index case (10 to 40 times the general population)
- 98% of patients with narcolepsy type 1 have human leukocyte antigen (HLA) DQB1*0602; 40–50% of patients with narcolepsy type 2 express this antigen. HLA DQB1*0602 is present in 12–30% of the general population.
- Autosomal recessive inheritance pattern
- Affects 12% of Asians and 25% of whites, and 38% of African Americans are gene carriers

**RISK FACTORS**
- Age (peaks at 15 and 35 years)
- Obesity
- Head trauma
- Central nervous system infectious disease
- Anesthesia
- Psychological stress
- Positive family history
- Recent influenza A, streptococcal infection, or H1N1 vaccine

**COMMONLY ASSOCIATED CONDITIONS**
Obstructive sleep apnea (OSA) (up to 25%), obesity, anxiety

---

**DIAGNOSIS**

**HISTORY**
- Classic pentad of EDS, cataplexy, sleep paralysis, and hypnagogic/hypnopompic hallucinations, and disrupted nocturnal sleep (five most common symptoms): Only 10–20% have all five.
- EDS and sleep attacks (cardinal symptom):
  - EDS is present in 100% of patients, usually the first initial symptom.
  - ICSD-3 classification for both type 1 and 2 requires EDS occurring almost daily for at least 3 months (1).
  - Patients may report refreshing daytime naps, with possible return of EDS in 1 to 2 hours.
  - Sudden sleep attacks (seconds) during stimulating situations such as driving and walking
- Cataplexy (65–75% patients)
  - Mainly associated with type 1 narcolepsy (1)
  - Sudden transient (seconds to minutes) episodes of total or partial loss of motor tone (buckling of knees, head dropping, sagging of jaw or weakness in arms, slurred speech, facial droop or grimace, etc.), triggered by strong emotions (such as laughing, anger, or fright)
  - Consciousness and memory are not impaired.
- Sleep paralysis
  - Transient (several minutes) inability to move, speak, or open the eyes either while falling asleep or upon awakening
  - During the event, breathing may be difficult because intercostal muscles are paralyzed and
– Patients are aware of their surroundings and are able to recall the event.
– Seen in 67% of patients who have narcolepsy with cataplexy and 49% narcolepsy without cataplexy

• Hypnagogic or hypnopompic hallucinations:
  – Vivid dreamlike experience in 30–60% patients with type 1 narcolepsy occurs during awakening (hypnopompic hallucinations) or at sleep onset (hypnagogic)
  – Hallucination commonly visual, tactile, or auditory.
  – Characteristic hallucinations include being attacked by animals or feeling that someone else is in the room.
  – 15% of type 2 patients experience these as well.

• Other reported history
  – Nocturnal insomnia and sleep fragmentation (difficulty maintaining sleep rather than initiating sleep)
  – Retrograde amnesia
  – Increased periodic limb movements
  – Depression and anxiety
  – Panic attacks and social phobia
  – Dream enactment behaviors
  – Weight gain is typically seen with progression.

**PHYSICAL EXAM**
• Unremarkable exam, but complete physical may help rule out other causes of EDS
• Deep tendon reflexes are either diminished or absent during an episode of cataplexy.

**DIFFERENTIAL DIAGNOSIS**
EDS is present in 4–28% of the general population, although most individuals are not narcoleptic. Possible etiologies include the following:
• Poor sleep hygiene
• Sleep apnea syndromes
• Epileptic seizures and syncope
• Idiopathic hypersomnia (5–10% with EDS)
• Psychiatric (depression, bipolar 2, and substance abuse/withdrawal)
• Sleep-related movement disorders (restless leg syndrome, periodic limb movements of sleep)
• Iatrogenic/secondary to medication (benzodiazepines; barbiturates; opioids; antihistamines; β-blockers; and some antipsychotics, antidepressants, and anticonvulsants)
• Poor sleep hygiene and habits leading to sleep deficit and chronic sleep deprivation (1)
• Circadian rhythm disorders (jet lag, shift work, delayed or advanced sleep phase disorders)
• Cataplexy disorders (Niemann-Pick type C, Prader-Willi syndrome, Norrie disease) (1)
• Hypersomnia in Parkinson disease
• Menstrual-associated hypersomnia
• Stroke (slurred speech and facial sagging seen in partial cataplexy)

**Pediatric Considerations**
Narcolepsy is rare before the age of 5 years. EDS is more often attributable to OSA, poor sleep hygiene, and the increased sleep requirements early in life. The recommended amount of sleep decreases with age: newborns 16 to 18 hr/day; preschool-aged children 11 to 12 hr/day; school-
aged children and teens 10 hr/day; adults 7 to 8 hr/day. Children can gain excessive weight, from 20 to 40 lb. Symptoms of EDS, sleep paralysis, and cataplexy might last longer than compared to adult population.

**DIAGNOSTIC TESTS & INTERPRETATION**

- Sleep log/actigraphy: First, ensure patient is getting 6 hours of sleep at night for at least 7 to 14 days.
- Prerequisites for valid multiple sleep latency test (MSLT) normal polysomnography (PSG) with at least 360 minutes of sleep, free of drugs that may alter sleep for at least 2 weeks, standardized sleep schedule for 7 days
- Primary diagnostic tool
  - PSG: An overnight PSG is performed (for ages $\geq$6 years), mainly to rule out other causes of EDS.
  - MSLT: performed the day after PSG if at least 6 hours of sleep and no sleep disorder explained by PSG
    - Four to five 20-minute naps at 2-hour intervals
    - Positive if rapid onset of REM (<15 minutes) in at least 2 of 5 sleeps (including baseline PSG) and shortened mean sleep latency (<8 minutes)
    - If MSLT negative, but strong clinical suspicion, repeat the test.
    - Antidepressants and stimulants should be discontinued prior to the test for at least 2 weeks.
- Scoring tools
  - Epworth Sleepiness Scale (ESS): Score ranges from 0 to 24, and >10 is suggestive of a sleep disorder rather than generalized fatigue; helpful for detecting response to medications
  - Fatigue severity scale: 9 item scale, which measures the severity of fatigue (helps differentiate between fatigue and sleep disorder)
  - Stanford Sleepiness Scale: Patients select 1 of 7 statements that best describe energy level, concentration, and sleepiness. Statements 4 to 7 may indicate excessive sleepiness.
  - Narcolepsy Severity Scale: a 15-item scale to assess the frequency, severity, and consequences of symptoms of narcolepsy type 1
  - Pediatric scoring tool: Epworth Sleepiness Scale for Children and Adolescents (a modified version of ESS) and Pediatric daytime sleepiness scale

**Follow-Up Tests & Special Considerations**

- Orexin: obtained via lumbar puncture, a level of 110 pg/mL or less in the cerebrospinal fluid (CSF) is indicative of narcolepsy; rarely performed
- HLA typing: particularly in children. It is supportive of diagnosis, lacks specificity.

**Diagnostic Procedures/Other**

- Narcolepsy type 1
  - EDS daily for $\geq$3 months
  - One of the following:
    - Cataplexy with positive MSLT
    - Low CSF orexin level $<$110 pg/mL or $<$1/3 of mean values in normal subjects
- Narcolepsy type 2
  - All of the above (with or without cataplexy) and normal CSF orexin level
  - It is a diagnosis of exclusion.
TREATMENT

GENERAL MEASURES
- Medications do not cure, but the goal is to minimize EDS and cataplectic episodes.
- Proper sleep hygiene and a regular sleep schedule.
- Well-timed 15- to 20-minute naps may be helpful.
- Drug therapy, if used, should be supplemented by various behavioral strategies.
- Avoid stimulants (alcohol, heavy meals, caffeine, nicotine).
- Maneuvers such as altering thoughts, placing tension on muscles, or pressing against a firm support might rapidly terminate cataplectic episodes.
- Maintaining warmer body temperature and consuming warm meals/drinks may improve wakefulness.
- Use safety precautions, particularly when driving. Untreated patients are at 10-fold at risk of accidents.
- Control can be obtained in 60–80% of patients.

MEDICATION

First Line
- **EDS**
  - Modafinil (Provigil):
    - First-line treatment for mild to moderate EDS
    - Works on dopaminergic, adrenergic, and histaminergic receptors of hypothalamus
    - Dose: 200 mg/day, maybe divided BID. Start with 100 mg; max dose 400 mg/day
    - Half-life of 15 hours
    - Adverse effects: headache, GI upset, increased metabolism of oral contraceptives with less rebound hypersomnia and does not affect blood pressure (BP); tolerance limited
    - Caution with cardiac diseases, may cause tachycardia and with oral contraceptive use as it decreases the efficacy
    - Not FDA approved in the pediatric population
  - Armodafinil (Nuvigil):
    - Enantiomeric form of modafinil with of the same 15 hour half-life, and has lower adverse effect profile
    - Dose: 150 to 250 mg every morning
    - Less adverse effects in comparison to modafinil: headache, xerostomia, Stevens-Johnson syndrome, and toxic epidermal necrolysis
    - Not FDA approved in the pediatric population
  - Pitolisant (Wakix): a new promising drug for narcolepsy and cataplexy approved for treatment in the EU
  - Clarithromycin: acts on GABA-A receptor, can be used for hypersomnia if alternative primary medication fails. Dose 500 mg BID (start with a 2 week trial period). Adverse effect: GI distress
- **Cataplexy:**
  - Sodium oxybate (Xyrem):
    - Only medication has proven effective and FDA approved for both EDS and cataplexy
    - Used for moderate to severe cases
    - Best option for improving nighttime sleep and FDA approved for the same
- Dose: 6 to 9 g/day divided BID; start with 2.25 g and increase by 1.5 g/day qwk; max dose: 9 g/day
- May take 8 to 12 weeks for full response
- Is a date rape drug; abuse potential
- May worsen sleep-disordered breathing in patients with OSA
- Overdose may lead to coma.

- Solriamfetol (Sunosi): newer medication (2019)
  - Start with 75 mg qD, increased based on response every 3 days to the max dose of 150 mg/day
  - Contraindicated with concomitant use of MAO-I or within 14 days of use
  - Abuse potential: monitor for signs of abuse and use caution in patients with a history of drug use

- Tricyclic antidepressants
  - Protriptyline: dose: 5 to 60 mg/day. Taper dose.
  - Clomipramine: dose: 25 to 75 mg/day
  - High side effect profile (anticholinergic): dry mouth, sedation, urinary retention, impotence

- Serotonin-norepinephrine reuptake inhibitors
  - Venlafaxine: dose: 75 to 300 mg/day. Start at 37.5 mg, max dose 375 mg/day. Taper dose to discontinue.
  - Fluoxetine: dose: 20 to 80 mg/day
  - Work by suppressing REM sleep
  - Not FDA approved
  - The patient may develop a tolerance to the anti-cataplectic drugs and can have rebound cataplexy when a drug is withdrawn. Taper to discontinue.

- Auxiliary symptoms (e.g., hypnagogic hallucination, sleep paralysis) require treatment less often than EDS and cataplexy, but anticataplectics are useful when symptoms are problematic.

**Second Line**

- EDS
  - Amphetamines: used if first line fail or patient unable to tolerate
    - Methylphenidate (Ritalin): dose: initial dose 5 to 10 mg/day divided BID or TID; max dose 60 mg/day, short acting, most potent amphetamine available; can be used in combination with modafinil and armodafinil
    - Dextroamphetamine: dose: initial dose 10 mg/day; can increase by 10 mg qwk to a max dose 60 mg/day divided BID or TID
    - Contraindicated in patients with hypertension (HTN)
    - Adverse reactions: headaches, irritability, HTN, psychosis, anorexia, habituation, rebound hypersomnia
    - If the patient develops a tolerance to stimulants, switch drug or drug holidays rather than increasing dose.
    - Highly addictive; high doses have been associated with frequent hospitalizations, arrhythmias, and psychiatric disturbances.

- Cataplexy
  - Selegiline: selective MAO-B inhibitor
    - Anticataplectic effective for EDS; 20 to 40 mg/day divided morning and noon
    - Doses >20 mg require a low-tyramine diet because the drug begins to lose selectivity.
ISSUES FOR REFERRAL
Unresponsive to primary medications and severe cataplexy may benefit from neurology referral.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Monitoring using scoring tools to gauge treatment effectiveness and symptom control
- Frequent BP checks and regular follow-ups (approximately every 6 months) are recommended for those on medication.

DIET
Those taking high doses of selegiline (>20 mg) require a low-tyramine diet.

PATIENT EDUCATION
- National Institute of Neurological Disorders and Stroke at https://www.ninds.nih.gov/Disorders/Patient-Caregiver-Education/Fact-Sheets/Narcolepsy-Fact-Sheet
- Narcolepsy Network, Inc., North Kingstown, RI 02852; www.narcolepsynetwork.org

PROGNOSIS
Narcolepsy is a lifelong disease. Symptoms can worsen with aging. In women, symptoms can improve after menopause.

REFERENCES

CODES
ICD10
- G47.429 Narcolepsy in conditions classified elsewhere w/o cataplexy
- G47.411 Narcolepsy with cataplexy
- G47.419 Narcolepsy without cataplexy

CLINICAL PEARLS
- Narcolepsy is an incurable, REM disorder, with 15 years of symptoms before a diagnosis is made.
- The classic tetrad includes EDS, cataplexy, sleep paralysis, and hypnagogic hallucinations, only cataplexy is pathognomonic for the disorder.
NASAL POLYPS
Andrew Dinh, DO ● Tharani Ravi, MD

BASICS
- Chronic benign inflammatory lesion of nasal mucosa
- Arise from ethmoidal cells but can arise from maxillary sinus mucosa although less common

DESCRIPTION
- Appearance of edematous pedunculated mass in the nasal cavity or within the paranasal sinus
- Often causes symptoms of blockage, discharge, or loss of smell
- Most commonly bilateral; if unilateral, malignancy should be on differential

EPIDEMIOLOGY
Incidence
Increases with age to a peak in the sixth decade

Prevalence
- ~4% in general population
- Much rarer in children: ~0.1% and associated with cystic fibrosis
- Asthma is present in up to 65% of patients

ETIOLOGY AND PATHOPHYSIOLOGY
Genetics
- Patients with nasal polyps are more likely than controls to report having a first-degree relative with nasal polyps (1)[B].
- No clearly delineated pathway; research has demonstrated separate TH1- and TH2-driven pathways (2)[B].

RISK FACTORS
An increased prevalence of nasal polyps has been described among textile workers who have been exposed to occupational dust, particularly among those with longer-duration exposure (1)[B].

GENERAL PREVENTION
Use of intranasal corticosteroids after polyp removal surgery has shown effectiveness against recurrence

COMMONLY ASSOCIATED CONDITIONS
- Asthma
- Bronchiectasis
- Aspirin hypersensitivity
- Allergic rhinitis
- Chronic sinusitis
- Allergic fungal sinusitis
- Cystic fibrosis
- Primary ciliary dyskinesia (Kartagener syndrome)
Laryngopharyngeal reflux

DIAGNOSIS
Made on the basis of the presence of sinonasal symptoms for more than 3 months and the visualization of polyps in the nasal cavity

HISTORY
Symptoms
- Rhinorrhea
- Nasal congestion
- Postnasal drainage
- Hyposmia
- Inability to breathe through nose
- Dull headaches
- Facial pain/pressure over the middle third of the face
- Sleep disturbance
- In some cases, there may be no symptoms.

PHYSICAL EXAM
Outside of rhinorrhea, sinus tenderness to palpation or visualization of polyp, there are no definitive physical exam findings.

DIFFERENTIAL DIAGNOSIS
- Chronic rhinosinusitis without polyps, rhinitis, structural abnormalities of the nose, and neurologic causes of hyposmia
- Benign versus malignant tumor:
  - Papilloma
  - Fibroma
  - Hemangioma
  - Neurilemmoma
  - Osteoma
  - Adenoma
  - Chondroma
  - Mycetoma
  - Encephalocele
  - Squamous cell carcinoma
  - Malignant melanoma

DIAGNOSTIC TESTS & INTERPRETATION
Follow-Up Tests & Special Considerations
- If large posterior nasal polyps, examine tympanic membrane for Eustachian tube dysfunction.
- If unilateral polyp, consider histologic exam to exclude malignancy.
- Test for cystic fibrosis in children with polyps.
- CT scanning (3)[C]:
  - May be helpful to corroborate history and endoscopic findings
  - Unable to differentiate polyp from other soft tissue masses
– Reveals extent of disease and is necessary to formulate a plan for surgical intervention if indicated

MRI (3)[C]:
– May aid in diagnosis if concern for neoplasia, mycetoma, or encephalocele

Diagnostic Procedures/Other

– Pale, translucent mass on anterior rhinoscopy
  – Most commonly on lateral wall of middle meatus
– Flexible/rigid endoscopy is required to assess the nasal cavity fully.
  – Gold standard for diagnosis

**TREATMENT**

**GENERAL MEASURES**

Goal is to reduce the size or eliminate nasal polyps because they can obstruct the nasal cavity and impair sense of smell, restrict breathing ability through nose, and obstruct drainage of sinuses

**MEDICATION**

**First Line**

Daily intranasal corticosteroid use with saline irrigation is first-line therapy (4)[A].

– Treat for a minimum of 12 weeks; minimal systemic absorption, side effects rare—minor nose bleeding is most common (2)[A]
  – Budesonide 256 μg/day
  – Beclomethasone dipropionate 320 μg/day
  – Fluticasone propionate 400 μg/day
  – Mometasone furoate 200 μg BID
  – For children, mometasone furoate is preferred.

**Second Line**

Consider short course of oral corticosteroids (14 to 21 days) and/or doxycycline (21 days) in symptomatic patients despite initial therapy (5)[A].

– Prednisone 30 to 50 mg daily (taper when indicated)
– Prednisolone 20 to 60 mg daily (taper when indicated)
– Doxycycline 200 mg once, followed by 100 mg daily (5)[A]

**ISSUES FOR REFERRAL**

– If unilateral polyp for biopsy evaluation.
– Consider referral to otorhinolaryngologist for endoscopic sinus surgery if severe obstruction symptoms or conservative management ineffective.

**ADDITIONAL THERAPIES**

Patients with persistent symptoms and have concurrent allergic rhinitis, consider:

– Systemic antihistamine
– Leukotriene pathway antagonist
– Allergy immunotherapy
SURGERY/OTHER PROCEDURES
- Most surgeries are approached endonasally.
  - The external (Caldwell-Luc) approach is used for more difficult cases but carries higher risk of complications.
- Functional endonasal sinus surgery has slightly lower revision rate than intranasal polypectomy. Both modalities provide effective symptom relief.
- Postoperative use of nasal corticosteroids delay the recurrence of nasal polyps and hence the timing of revision surgery (2).
- Postoperative use of steroid-releasing stents to prevent polyp recurrence by decreasing mucosal inflammation (2)

COMPLEMENTARY & ALTERNATIVE MEDICINE
Based on one randomized clinical trial, the addition of subcutaneous dupilumab to topical corticosteroids reduced endoscopic nasal polyp burden after 16 weeks, but further studies are needed to determine efficacy (5)[C].

ONGOING CARE
- Recurrence up to ~40% (1)
- Use of intranasal corticosteroids after polyp removal surgery has shown effectiveness against recurrence.
- Recurrence twice as likely in those with asthma

PROGNOSIS
Persons who undergo surgery have great improvements in symptoms, but recurrence rate is high (6,7)[B].

COMPLICATIONS
- Acute/chronic sinus infections
- Heterotrophic bone formation within the sinus cavity may occur.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- J33.9 Nasal polyp, unspecified
- J33.0 Polyp of nasal cavity
- J33.8 Other polyp of sinus

CLINICAL PEARLS

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence as well as to improve nasal congestion.
- Short-course oral corticosteroids and/or doxycycline may be considered in those with persistent symptoms.
- Asthma is a common concomitant diagnosis and is often previously undiagnosed.
- Aggressive medical and surgical treatment improves asthma outcomes.
- Allergy testing can be helpful.
- Patients with severe obstruction should be referred for surgery.
- Referral for unilateral nasal polyp biopsy.
NEPHROTIC SYNDROME
Hanadi Abou Dargham, MD • Nandhini Veeraraghavan, MD, CAQSM, FAAFP

BASICS
DESCRIPTION
- A clinical syndrome of massive proteinuria (>3.5 g/1.73 m^2/24 hr), hypoalbuminemia (<3 g/dL), severe hyperlipidemia (total cholesterol often >10 mmol/L) (380 mg/dL), clinical evidence of peripheral edema, with risk for thrombotic disease
- Includes both primary (idiopathic) and secondary forms
- Associated with many types of kidney disease

EPIDEMIOLOGY
Based on definitive diagnosis
- Diabetic nephropathy: most common cause of secondary nephrotic syndrome (1)
- Minimal change disease (MCD)
  - Most common cause of nephrotic syndrome in children <10 years (90%)
  - Peaks at 2 to 8 years of age
  - Associated with drugs (mainly NSAIDs) or lymphoma in adults
- Amyloidosis: 7–14% of idiopathic nephrotic syndrome—two renal types primary (AL) and secondary (AA)
- Lupus nephropathy (LN): Adult women are affected about 10 times more often than men.
- Focal segmental glomerulosclerosis (FSGS)
  - 35% of nephrotic syndrome in adults
  - Most common primary nephrotic syndrome in African Americans
  - Has both primary (idiopathic) and secondary forms (associated with HIV, morbid obesity, reflux nephropathy, previous glomerular injury)
- Membranous nephropathy
  - Most common cause of primary nephrotic syndrome in adults (40%)
  - May be primary or secondary associated with malignancy, Hep B, autoimmune diseases, thyroiditis, and certain drugs
- Membranoproliferative glomerulonephritis (MGN)
  - May be primary or secondary
  - May present in the setting of a systemic viral or rheumatic illness

ETIOLOGY AND PATHOPHYSIOLOGY
- Increased glomerular permeability to protein macromolecules, especially albumin
- Podocytes injury is the most common finding in diseases that cause primary nephrotic syndrome.
- Mutations in number of genes regulating podocyte proteins were identified in families with inherited nephrotic syndrome.
- Edema results primarily from renal salt retention, with arterial underfilling from decreased plasma oncotic pressure playing an additional role.
- Hyperlipidemia is thought to be a consequence of increased hepatic synthesis resulting from
low oncotic pressure and urinary loss of regulatory proteins.

- The hypercoagulable state that can occur in some nephrotic states is likely due to loss of antithrombin III in urine.

Primary renal disease:
- MCD
- FSGS
- MGN
- IgA nephropathy

Secondary renal disease (associated primary renal disease shown in parentheses):
- Diabetic nephropathy
- Amyloidosis
- LN
- FSGS
- Infections (MGN)
- Cancer (MCD or MGN)
- Drugs (MCD or MGN)

**Genetics**
Genetic factors are likely to play a role in the susceptibility and clinical unresponsiveness to glucose steroids, but the exact mechanism remains largely unknown.

**RISK FACTORS**
- Drug addiction (e.g., heroin [FSGS])
- Hepatitis B and C, HIV, other infections
- Immunosuppression
- Nephrotoxic drugs
- Vesicoureteral reflux (FSGS)
- Cancer (usually MGN, may be MCD)
- Chronic analgesic use/abuse (NSAIDs)
- Preeclampsia
- Diabetes mellitus

**GENERAL PREVENTION**
In general, there are few preventive measures, including avoidance of known causative medications including NSAIDs, gold, penicillamine, and captopril; avoidance of heroin abuse and tight glycemic control.

**DIAGNOSIS**

**HISTORY**
The history is key in pinpointing the cause of nephrotic syndrome.
- Inquire about signs or symptoms of systemic disease: joint complaint, rash, edema, infectious complaint, fevers, anorexia, oliguria, foamy urine, acute flank pain, and hematuria.
- Obtain a recent drug history for medications that may be causative, especially NSAIDs.
- Assess for risk factors.

**PHYSICAL EXAM**
A complete physical exam may discover clues to systemic disease as a potential cause and/or may suggest the severity of disease.

- Fluid retention: abdominal distention, abdominal fluid shift, extremity edema, puffy eyelids, scrotal swelling, weight gain, shortness of breath. Pericardial rub and decreased breath sounds with pleural effusions may develop.
- Arterial hypertension is found in 25% of the cases.
- Orthostatic hypotension
- Macroscopic hematuria is rare, but microscopic hematuria is present in 20% of the cases.

**ALERT**
The potential for thromboembolic disease leading to pulmonary embolism is one of the most life-threatening aspects of a patient who is actively nephrotic.

**DIFFERENTIAL DIAGNOSIS**
- Edema and proteinuria: See “Etiology and Pathophysiology.”
- Edema alone: Other diseases to rule out in patients who have edema without proteinuria include congestive heart failure, cirrhosis, hypothyroidism, nutritional hypoalbuminemia, protein-losing enteropathy.

**DIAGNOSTIC TESTS & INTERPRETATION**
No guidelines are available for the investigation of nephrotic syndrome. Blood workup should be based on the clinical presentation.

**Initial Tests (lab, imaging)**
- Confirm proteinuria if present: by urine dipstick initially (3+ or 4+ readings) and then quantitate by 24-hour urine or spot urine protein-to-creatinine ratio.
- Rule out urine infection with urine culture.
- Full blood count and coagulation screen
- Renal function tests: BUN, creatinine with estimated glomerular filtration rate (GFR)
- Glucose to rule out overt diabetes
- Serum albumin that is often <2.5 g/dL in NS.
- Consider blood cultures to rule out a postinfectious process.
- Lipid panel
- Liver function tests to exclude liver disease or infection
- Look for autoimmune disease.
  - Antinuclear antibody and/or antidouble-stranded DNA positivity suggest lupus.
  - Complement levels (C3/C4 and total hemolytic complement): A low C3 may suggest a postinfectious or membranoproliferative process, whereas both low C3 and C4 point to lupus.
- Serum protein electrophoresis/urine immune electrophoresis to rule in a paraproteinemia
- Hepatitis B and C screen
- Measurement of cryoglobulins
- HIV and syphilis serology
- Urinalysis to evaluate for the presence of cellular casts
- Renal US to verify the presence of two kidneys of normal shape and size
- Chest x-ray to detect presence of pleural effusion or infection
- If thrombosis is suspected:
  - Doppler US of the legs
– MRI or venography for renal vein thrombosis
– Ventilation/perfusion nuclear medicine lung scan and/or CT angiography may be required to rule out pulmonary embolism.

**Diagnostic Procedures/Other**
Renal biopsy is standard in determining the underlying cause of nephrotic syndrome.
- Rarely done in children with first episode of nephrotic syndrome because MCD is common and empiric steroid therapy is the standard of care
- Required to confirm the clinical diagnosis in adults and assist with making a treatment plan (1)
- Contraindications to renal biopsy include small kidneys, renal tumor or bilateral renal cysts, active infection, severe malignant hypertension, hydronephrosis, bleeding diathesis, uncooperative patient.

**Test Interpretation**
- Light microscopy
  - May see nothing (e.g., MCD)
  - Sclerosis (e.g., FSGS or diabetic nodules in diabetes)
  - Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, LN, or postinfectious GN.
- Immunofluorescence: Mesangial IgA suggests IgA nephropathy, Henoch-Schönlein purpura; other staining patterns are specific for other disease processes.
- Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

**TREATMENT**

**MEDICATION**

**First Line**
- Edema: salt restriction and salt-wasting diuretics (loop and thiazide diuretics) (2)[A]:
  - Salt restriction to <2 to 3 g sodium per day
  - Restrict fluid intake to <1.5 L/day if hyponatremic.
  - Target weight loss of 0.5 to 1.0 kg/day (1 to 2 lb/day)
- Edema should be corrected slowly to avoid acute hypovolemia, electrolyte disturbances, acute renal failure, and thromboembolism as a result of hemoconcentration, and diuretic dose should be increased in comparison to the general population.
- Hyperlipidemia:
  - Is reversed with resolution of the disease
  - The role of dietary modification is unproven yet.
- Statins have been shown to improve endothelial function (2)[A] and may decrease proteinuria (3)[A], but effect on GFR and preservation of renal function is small. The major role for statin use is in cardiovascular risk reduction.
- ACE inhibitors or angiotensin II receptor blockers are thought to reduce proteinuria, hyperlipidemia, thrombotic tendencies, progression of renal failure, and to control hypertension, if present (4)[A].
- For steroid-responsive disease (MCD and FSGS), steroids dosed in consultation with nephrologist
Many of the nephrotic diseases will require escalation in therapy above steroids. These include rapidly relapsing forms as well as MGN, LN, and IgA nephropathy. Bolus steroids and other immunosuppressives are required in this circumstance (cyclophosphamide, mycophenolate mofetil, chlorambucil, cyclosporine) (5)[A].

Rituximab, anti-CD20 and abatacept, anti–B7-1, combined with steroids or other immunosuppressive agents, has demonstrated early promise in the treatment of refractory nephrotic syndrome (6)[B].

Randomized controlled data have been insufficient to determine which patients require prophylactic anticoagulation (7)[A] and for how long. Common practice is to anticoagulate with heparin and then warfarin in patients who have persistent nephrotic-range proteinuria. This decision is made based on the patient’s history of edema, hypoalbuminemia, thromboembolism, or immobility.

Hypocalcemia from vitamin D loss should be treated with oral vitamin D.

ISSUES FOR REFERRAL
Consultation with a nephrologist is often required to assist with renal biopsy to confirm diagnosis and to assist with management of edema. Cytotoxic medications may be called for, depending on the disease process, and this may best be handled by a nephrologist.

ADDITIONAL THERAPIES
Ambulation or range of motion exercises to lower risk of deep vein thrombosis (DVT)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: respiratory distress, sepsis/severe infection, thrombosis, renal failure, hypertensive urgency/emergency, or other complications
- Discharge criteria: Hemodynamically stable patients without complications may be managed as outpatients.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Frequent monitoring is required for relapse, disease progression, and for detecting signs of toxicity of medical management.
- Reevaluate for azotemia, urine protein, hypertension, edema, loss of renal function, cholesterol, and weight.

DIET
Muscle wasting and malnutrition are major problems in severe nephrotic syndrome. Optimal diet includes:
- Normal protein (1 g/kg/day)
- Low fat (cholesterol)
- Reduced sodium (<2 g/day)
- Supplemental multivitamins and minerals, especially vitamin D and iron
- Fluid restriction if hyponatremic
PATIENT EDUCATION

- Printed material for patients: National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 800-622-9010
  - Childhood nephrotic syndrome
  - Diabetes and kidney disease
  - Focal glomerulosclerosis
- Web site: National Institutes of Health: nephrotic syndrome

PROGNOSIS

- Nephrotic syndrome in children (MCD) is typically self-limited and carries a good prognosis. In the adult, the prognosis is variable. Proteinuria is the most important adverse prognostic factor that leads to rapid progression to end-stage renal failure.
- Complete remission is expected if the basic disease is treatable (infection, malignancy, drug induced); otherwise, a relapsing and remitting course is possible, with progression to dialysis seen in more aggressive forms (diabetic glomerulosclerosis and FSGS).

COMPLICATIONS

- Thromboembolism:
  - Deep vein, renal vein, or central venous thrombosis may occur. Arterial thrombosis is very rare.
  - The risk appears to be greater the lower the serum albumin.
  - Pulmonary embolism is a known complication.
- Pleural effusion
- Symptomatic hypovolemia
- Ascites
- Hyperlipidemia, cardiovascular disease
- Acute renal failure, progressive renal failure
- Protein malnutrition/muscle wasting
- Infection secondary to low serum IgG concentrations, reduced complement activity, and depressed T-cell function: peritonitis, pneumonia, or cellulitis
- Loss of vitamin D (vitamin D–binding protein loss in urine) leading to bone disease
- Proximal tubular dysfunction resulting in glucosuria, aminoaciduria, phosphaturia, bicarbonaturia, and vitamin D deficiency

Acute Kidney Injury; Amyloidosis; Diabetes Mellitus, Type 1; Diabetes Mellitus, Type 2; Glomerulonephritis, Acute; HIV/AIDS; Lupus Erythematosus, Discoid; Multiple Myeloma

CODES

ICD10

- N04.9 Nephrotic syndrome with unspecified morphologic changes
- N04.1 Nephrotic syndrome with focal and segmental glomerular lesions
- N04.2 Nephrotic syndrome with diffuse membranous glomerulonephritis

CLINICAL PEARLS

- Nephrotic syndrome is a clinical syndrome of >3.5 g/day proteinuria, hypoalbuminemia, hyperlipidemia, and edema often associated with diabetes and NSAIDs use.
- Pediatric nephrotic syndrome typically carries a good prognosis and is more easily treated with steroids, although recurrences are common.
- Nondiabetic adults with nephrotic syndrome will require a renal biopsy to determine cause.
- Have a high index of suspicion for symptoms that may represent an embolic event in patients with nephrotic syndrome.
NEUROFIBROMATOSIS TYPE 1
Michele Roberts, MD, PhD

BASICS

DESCRIPTION

- Neurofibromatosis types 1 (NF1) and 2 (NF2) are neurocutaneous syndromes (phakomatoses).
  - Although they share a name, they are unrelated.
  - NF1, the most common of the phakomatoses, is a multisystem disorder that may affect any organ: the defining feature of NF1 is the neurofibroma, a nerve sheath tumor that forms in intimate association with spinal, peripheral, or cranial nerves (1). It is also characterized by café au lait macules (CALM), axillary and inguinal freckling, Lisch nodules, choroidal freckling.
  - NF2 is a rare condition that causes bilateral vestibular schwannomas.
- System(s) affected: musculoskeletal; nervous; skin/exocrine; cardiovascular; neuro-ophthalmologic
- Synonym(s): von Recklinghausen disease, formerly peripheral NF

EPIDEMIOLOGY

Incidence

- Predominant sex for NF1: male = female
- Birth incidence NF1: 1:2,500 to 3,000

Prevalence

1:3,000 to 4,000

ETIOLOGY AND PATHOPHYSIOLOGY

- Neurofibromin is a GTPase–activating protein that acts as a tumor suppressor by down-regulating p21-ras, a cellular proto-oncogene that enhances cell growth and proliferation.
- Some clinical manifestations of NF1, such as CALMs, require biallelic inactivation of NF1. Others, such as malignant peripheral nerve sheath tumors (MPNSTs), result from haploinsufficiency in combination with mutations in other genes, such as TP53.
- Neurofibromas are benign tumors composed of Schwann cells, fibroblasts, mast cells, and vascular components that develop along nerves.

Genetics

- Caused by a mutation in the NF1 gene on chromosome 17q11.2; autosomal dominant inheritance; protein product is called neurofibromin.
- 50% of cases are due to de novo mutations, mostly paternal; likelihood increases with paternal age.
- Prenatal diagnosis is possible if mutation is known.
- Gene is large (~60 exons), with >3000 different germline mutations causing NF1. Molecular technology can detect 95% of clinically important NF1 mutations, but clinical diagnosis frequently can be made in childhood.
- Although expressivity is extremely variable, even within a family, the p.Arg1038Gly missense substitution correlates with a mild phenotype without neurofibromas or other complications.
RISK FACTORS
- Having an affected first-degree relative is a diagnostic criterion for NF1, although relatives may be unaware that they have NF1.
- Affected individuals with a positive family history (or a new mutation) have a 50% risk of transmitting NF1 to each offspring; 1 in 12 will be severely affected.

COMMONLY ASSOCIATED CONDITIONS
- Congenital heart disease, pulmonary stenosis, hypertension, renal artery stenosis
- Learning disabilities (50–75%)

DIAGNOSIS
NF1 can be diagnosed by routine exam by age 4 years, with attention to skin stigmata; diagnostic criteria include ≥2 of the following (3):
- ≥6 café au lait (light brown) macules (CALMs), ≥5 mm in prepubertal individuals, or ≥15 mm in adults
- ≥2 neurofibromas of any type or 1 plexiform (uncircumscribed) neurofibroma
- Axillary or inguinal freckling
- ≥2 Lisch nodules (benign iris hamartomas)
- Optic glioma by MRI
- Characteristic osseous lesions: sphenoid dysplasia, long-bone cortical thinning, ribbon ribs, angular scoliosis
- First-degree relative with NF1 by above criteria
- Prenatal diagnosis is possible with known mutation or by linkage testing (with positive family history), although not predictive of clinical course.

HISTORY
- Family history of a first-degree relative with NF1
- Manifestations generally are not visible at birth, although plexiform neurofibromas are usually congenital, and tibial bowing is congenital.
- In addition to cutaneous lesions, NF1 may present with painful neurofibromas, pathologic fractures, or headaches secondary to hypertension caused by pheochromocytomas.
- Optic gliomas may present as involuntary eye movement, squinting, loss of vision, or as diencephalic syndrome.

PHYSICAL EXAM
- Skin
  - CALMs, usually the presenting feature of NF1, develop before age 3 years. Evenly pigmented, irregularly shaped (coast of California), light-brown macules seen in 97% of patients with NF1; many unaffected individuals have 1 to 3 such macules.
  - Neurofibromas: can be soft or firm, cutaneous, subcutaneous, or plexiform; buttonhole invagination is pathognomonic. Cutaneous neurofibromas usually appear during late childhood or adolescence.
  - Plexiform neurofibromas present in up to 50% o Usually congenital; may be subtle in infancy
Freckling or hypertrichosis may be present over plexiform neurofibromas; may affect underlying structures or focal hyperplasia.

- Many are internal, not obvious on exam.
- Most grow slowly but can have rapid growth, especially in early childhood.
- Evaluate for new or progressive lesions. Rapidly growing cutaneous lesions should be evaluated.
- Axillary freckling (Crowe sign) or inguinal freckling (91%)

Ophthalmologic
- Lisch nodules in 30%: well-defined, dome-shaped, gelatinous hamartomatous lesions projecting from the iris, varying from clear yellow to brown
- Essentially unique to NF, Lisch nodules are asymptomatic; significant only for diagnosis
- Pallor or atrophy of optic disc, bulging of orbit, loss of vision may be signs of optic glioma.
- Choroidal freckling

Skeletal
- Scoliosis and vertebral angulation
- Localized bone hypertrophy, especially of the face
- Limb abnormalities:
  - Pseudoarthrosis of the tibia
  - Tibial dysplasia (anterolateral bowing of the tibia)
  - Nonossifying fibromas of the long bones in adolescents and adults are uncommon but can increase risk of fracture.

Pay particular attention to neurologic examination (asymmetry) or new focal pain.

- Measure BP yearly. Hypertension is more common in patients with NF1 and could be secondary to renal artery stenosis, aortic stenosis, pheochromocytoma.
- Evaluate neurodevelopmental progress in children. Learning disabilities occur in 50–75%.

**DIFFERENTIAL DIAGNOSIS**

Familial café au lait spots (autosomal dominant, no other NF1 features), Legius syndrome, constitutional mismatch repair deficiency syndrome (CMMRD), NF2, Watson syndrome, LEOPARD syndrome, McCune-Albright syndrome, neurocutaneous melanosis, proteus syndrome, lipomatosis, Jaffe–Campanacci syndrome

**Geriatric Considerations**
In NF1, cutaneous lesions and tumors increase in size and number with age.

**Pediatric Considerations**
- Children who have inherited the NF1 gene of an affected parent usually are identified by age 1 year, but external stigmata may be subtle.
- If no stigmata noted by age 2 years, NF is unlikely, but the child should be reexamined. Diagnosis usually can be made by age 4 years using NIH criteria (3), although young children may have multiple CALMs but no other stigmata.
- Periodic ophthalmological evaluations at increasing intervals after 10 years of age (1)[C].
- Molecular confirmation may be appropriate, especially with atypical presentation.

**DIAGNOSTIC TESTS & INTERPRETATION**
- Molecular genetic testing often not necessary for diagnosis
- Confirmatory genetic testing is appropriate in those suspected of having NF1 but do not fulfill diagnostic criteria or for prenatal diagnosis or preimplantation genetic diagnosis (PGD).
• Molecular genetic testing of the NF1 gene can identify mutations in ~95% of those with a diagnosis.
• Multistep pathogenic variant detection with cDNA and gDNA sequence analysis recommended if molecular genetic testing is indicated. NF1 is caused by a wide variety of mutations in the NF1 gene.

Initial Tests (lab, imaging)
• Characteristic radiographic findings: sphenoid dysplasia, long bone cortical thinning, ribbon ribs, angular scoliosis. Screening radiographs of the knees in adolescents is controversial. CT can demonstrate bony changes.
• MRI findings of the orbits, brain, or spine (86%). Routine head MRI scanning in asymptomatic individuals is controversial. Optic gliomas (on MRI, 11–15%) may lead to blindness. Although areas of increased T2 signal intensity (unidentified bright objects) are common on brain MRI, they are not diagnostic of NF1 and likely of no clinical significance.
• The NIH Consensus Development Conference does not recommend routine neuroimaging as a means of establishing a diagnosis, although modification of diagnostic criteria is discussed (3) [C].

Diagnostic Procedures/Other
• Ophthalmologic evaluation, including slit-lamp exam of the irides; visual field testing to evaluate optic gliomas
• Neuropsychological testing: intelligence usually normal but may have significant deficits in language, visuospatial skills, and neuromotor skills

TREATMENT

MEDICATION

First Line
No specific therapeutic agents; symptoms are treated as they arise (e.g., anticonvulsants for seizures, medications for ADHD, management of blood pressure, vitamin D supplementation for osteopenia in those with low vitamin D levels).

Second Line
• Several biologically targeted therapies (e.g., mTOR inhibitors, imatinib, selective MEK inhibitors) that inhibit pathways responsible for tumor growth have been evaluated in clinical trials (1).
• Clinical trials with farnesyltransferase inhibitors, multi-kinase inhibitors, and anti-fibrotic agents have not been successful (1).
• A phase II trial of selumetinib is underway in adults and children with NF1 and symptomatic plexiform neurofibromas (1).
• Multiple clinical trials for NF1 are recruiting patients.

ISSUES FOR REFERRAL
• Patients with more than minimal manifestations of NF1: Refer to a multidisciplinary NF clinic.
• Referral for psychosocial issues
• Educational intervention for children with learning disabilities or ADHD (40%)
Early referral to orthopedics for congenital tibial bowing

ADDITIONAL THERAPIES
- Occupational therapy for children with NF1 who present with fine motor difficulties
- Laser therapy not recommended for CALMs.
- The Children’s Tumor Foundation (CTF) has established the NF Clinical Trials Consortium and the CTF NF Clinic Network to facilitate clinical trials.

SURGERY/OTHER PROCEDURES
- Dermal neurofibromas can cause itching, stinging, pain, tenderness, bleeding, and cosmetic problems. Management may involve surgical removal, laser ablation of small lesions, electrodessication, emollients, camouflage make-up, psychological support (1).
- Plexiform neurofibromas, usually benign, can cause pain, disfigurement, neurological deficit, difficulty swallowing and breathing, and severe hemorrhage, and are at risk for malignant transformation. Treatment is surgical (1)[C].
- Surgical treatment for dystrophic scoliosis (although non-dystrophic scoliosis frequently can be managed conservatively, with bracing) or malignancy (especially MPNST)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
NF1 health supervision 2008 guidelines:
- Infancy to 1 year
  - Growth and development: mild short stature, macrocephaly (increased brain volume); aqueductal stenosis/obstructive hydrocephalus
  - Check for focal neurologic signs or asymmetric neurologic exam.
  - Skeletal abnormalities, especially spine and legs
  - Neurodevelopmental progress
- 1 to 5 years
  - CALMs and axillary freckling have no clinical significance.
  - Annual ophthalmologic exam
  - Brain MRI for visual changes, persistent headaches, seizures, marked increase in head size, plexiform neurofibroma of the head
  - Assess speech and language: hypernasal speech due to velopharyngeal insufficiency and delayed expressive language development.
  - Developmental evaluation of learning and motor abilities; may benefit from speech/language and/or motor therapy, and special education
  - Monitor BP annually.
- 5 to 13 years
  - Evaluate for skin tumors causing disfigurement, and obtain consultation if surgery is desired to improve appearance or function.
  - Evaluate for premature or delayed puberty. If sexual precocity is noted, evaluate for an optic glioma or hypothalamic lesion. Review the effects of puberty on NF.
  - Evaluate for learning disabilities and ADHD.
  - Evaluate social adjustment, development, and school placement.
  - Monitor ophthalmologic status yearly until age 8 years; complete eye exam every 2 years.
– Monitor BP annually.
– Refer patient to a clinical psychologist or child psychiatrist for problems with self-esteem.
– Discuss growth of neurofibromas during adolescence and pregnancy.
– Counsel parents about discussing diagnosis with child.

13 to 21 years
– Examine the adolescent for abnormal pubertal development.
– Skin examination for plexiform neurofibromas and neurologic exam for findings suggestive of deep plexiform neurofibromas; surgical consultation for signs of pressure on deep structures
– Continue to monitor BP yearly.
– Ophthalmologic exam every 2 years until age 18 years
– Discuss genetics of NF1 or refer for genetic counseling.
– Discuss sexuality, contraception, and reproductive options.
– Discuss effects of pregnancy on NF1, if appropriate. Neurofibromas may enlarge and new tumors may develop during pregnancy.
– Review prenatal diagnosis or refer to a geneticist.

PATIENT EDUCATION
● Genetic counseling and patient education regarding future complications and family planning. Support groups are important.
● Children’s Tumour Foundation, Washington University NF Center, Neuro Foundation

PROGNOSIS
Variable; most patients have a mild expression of NF1 and lead normal lives. Life expectancy may be reduced by ~8–21 years, with an excess of deaths in individuals <40 years of age (1).

COMPLICATIONS
● Disfigurement: Skin neurofibromas develop primarily on exposed areas. The number tends to increase with puberty or pregnancy.
● Scoliosis: 10–30% (most cases mild); bowing of long bones, 2%; osteopenia and osteoporosis
● A large head is common but rarely associated with hydrocephalus.
● Increased risk of malignancy: MPNST (5–10%) usually in adults (3), especially within the field of previous radiotherapy for plexiform neurofibroma
● CNS tumors (5–15%), optic pathway glioma most common, most often asymptomatic but usually presents before age 6 years if symptomatic; symptomatic lesions usually stable or slowly progressive
● High relative risk (RR) for uncommon malignancies
● Increased risk for pheochromocytoma, rhabdomyosarcoma, leukemia, Wilms tumor
● RR for cancer of the esophagus (3.3), stomach (2.8), colon (2.0), liver (3.8), lung (3.0), bone (19.6), thyroid (4.9), malignant melanoma (3.6), non-Hodgkin lymphoma (3.3), chronic myeloid leukemia (6.7), female breast (2.3), and ovary (3.7)
● Learning disability: ~50%; reduction in average IQ (~85) may be associated with ADHD; cognitive impairment in 4–8%.
● Neuropsychological phenotype: behavioral problems, executive dysfunction, reduced working memory; literacy, numeracy, and visual spatial difficulties.
● GI neurofibromas may cause GI disturbances.
● Seizures: 6–7%
- Hypertension frequent in adults, may occur in childhood
- Disorders of puberty

**Pregnancy Considerations**
Increased risk of perinatal complications, stillbirth, intrauterine growth constriction; risk of cord compression and outlet obstruction by pelvic neurofibromas

**REFERENCES**

**CODES**

**ICD10**
- Q85.01 Neurofibromatosis, type 1

**CLINICAL PEARLS**

- NF1 manifests marked clinical variability. External stigmata may be subtle or absent in young children. Minimally affected children may become severely affected adults.
- A single CALM is of no concern in a child, but having ≥6 is a diagnostic criterion for NF1.
NEUROPATHIC PAIN
Michael J. Arnold, MD

BADICS

DESCRIPTION
- Defined as pain caused by direct nerve injury in either peripheral or central nervous system
- Can exist without ongoing disease
- Can arise from damage to nerve pathways at any point from terminals of the peripheral nociceptors to cortical neurons in the brain
- Causes include traumatic nerve injury, infection, metabolic injury, autoimmune disease, neoplasm, drugs, radiation, and neurovascular disorders.

EPIDEMIOLOGY

Prevalence
Includes chronic conditions that affect up to 10% of the population
- Cancer—up to 20% have neuropathic pain from either cancer or treatment
- Herpes zoster—lifetime incidence is ~25%. Up to 10% develop chronic postherpetic neuralgia.
- HIV—33 million people infected across the world; ~35% have neuropathic pain.
- Diabetic neuropathy—affects 0.8% of population

ETIOLOGY AND PATHOPHYSIOLOGY
- Positive symptoms due to changes in peripheral nerves, loss of inhibitory mechanisms in central nervous system (CNS), and central sensitization
- Negative symptoms (sensory deficits) reflect neural damage.
- Associated with numerous conditions, including:
  - Demyelinating disorders (multiple sclerosis, Guillain-Barré syndrome)
  - Neoplasm (primary/metastatic)
  - Neurovascular (central poststroke syndrome, diabetes, trigeminal neuralgia)
  - Autoimmune disease (Sjögren syndrome, polyarteritis nodosa)
  - Structural disease (herniated disc disease) (1)

RISK FACTORS
- General risk factors include older age, female gender, physical inactivity, and manual occupation.
- There is growing evidence of genetic factors.
- Includes conditions that cause nerve damage or potentiate symptoms from damaged nerves:
  - Diabetes
  - Herpes zoster
  - Trigeminal neuralgia
  - HIV
  - Lyme disease
  - Cancer and chemotherapy
  - Stroke
  - Multiple sclerosis
  - Trauma
– Surgery
  – Limb amputation
  – Nutritional deficiencies
  – Medications

COMMONLY ASSOCIATED CONDITIONS
- Depression/anxiety: presence worsens quality of life significantly
- Insomnia
- Substance abuse

DIAGNOSIS
Diagnosis is based primarily on history (e.g., underlying disorder and distinct pain qualities) and the findings on physical examination (e.g., pattern of sensory disturbance) (1,2)[C].

HISTORY
- History should include:
  – Onset and duration of symptoms: location, intensity, character, temporal profile,
    exacerbating factors, concomitant symptoms, and effect on symptoms. Past medical and
    surgical history, psychosocial history, substance use (especially alcohol) can highlight
    possible etiologies.
  – Sensory descriptors: numbness, weakness, reduced sensation to touch, pinprick,
    temperature, or vibration; decreased proprioception
- Pain often described as burning, shock-like, or tingling (1,2)
- No single feature is diagnostic (2).

PHYSICAL EXAM
- Positive symptoms and signs (2)
  – Hyperalgesia: (abnormally increased pain response to stimulus) including sharp or blunt
    pressure, heat or cold
  – Alldynia: (pain from nonpainful stimulus) evoked by light touch, clothing, or bed sheets
- Negative symptoms—can be present in the same area as positive (2)
  – Hypoesthesia (abnormally reduced sensation of a tactile stimulus) to touch or temperature
- Motor (2)
  – Symptoms may include weakness, fatigability, decreased range of motion, joint stiffness,
    and spontaneous muscle spasm.
  – Signs may include hypotonia, tremor, dystonia, ataxia, hypo-/hyperreflexia, motor neglect.
- Sensory examination (1,2)
  – Light touch, pinprick, vibration sense, and proprioception may be diminished or amplified.
  – Sensory disturbance may extend beyond a discrete nerve territory.
- Skin examination
  – Alterations in temperature, color, sweating, and hair growth suggestive of sympathetic
    nervous system involvement, such as in complex regional pain syndrome (CRPS) (2)
  – Residual dermatomal scars can indicate previous herpes or herpes zoster (shingles)
    infection.
  – Acanthosis nigricans can indicate diabetes.
DIFFERENTIAL DIAGNOSIS
- Nociceptive pain: induced by transmission impulses along peripheral nociceptors due to tissue damage
- Differentiate by clinical signs and symptoms, mechanisms, and therapeutic management.

DIAGNOSTIC TESTS & INTERPRETATION
Lab tests may suggest etiology of pain. Neurologic testing establishes distribution but does not yet provide benefit in determining treatment (3)[C].

Initial Tests (lab, imaging)
None specifically for neuropathic pain but can rule in or out a cause of symptoms
- Serum vitamin B₁₂
- Thyroid-stimulating hormone (TSH)
- Rapid plasma reagin (RPR) or venereal disease research laboratory (VDRL) test
- Fasting glucose/hemoglobin A₁c, creatinine, Lyme serology

Follow-Up Tests & Special Considerations
- Neuroimaging of affected area—only useful for verifying pathology for procedure or surgery
- Nerve conduction study (NCS): Focus on large nerves limits utility for most neuropathic pain; exceptions include compression neuropathies such as carpal tunnel syndrome (1).
- Electromyography: also large nerve focus, results do not apply to Aδ and C pain fibers (1).
- Quantitative sensory testing: measures patient perceptual response to quantified pain stimulus; being studied to find sensory types of neuropathic pain in hopes of improving therapy (1)
- Skin biopsy: used for population studies, decreased nerve fiber density seen in some neuropathic conditions (fibromyalgia, HIV neuropathy) (1)

TREATMENT

GENERAL MEASURES
- Due to multiple neuropathic pain pathways, all medications have limited efficacy and minority of patients have significant benefit at tolerable doses.
- Physical and occupational therapy can help with functional goals.
- Cognitive-behavioral therapy has proven benefit (3)[B]. Mindfulness-based stress reduction has benefit in post-herpetic neuropathy.

MEDICATION
- The efficacy of systemic drug treatments is generally not dependent on the etiology of the underlying disorder (2).
- Combined therapy (polypharmacy) likely more effective than increasing dose of single medicine.
- Treatment needs to be individualized.
- Thought to be resistant to acetaminophen or NSAIDs but often used with some benefit (2)[C]

First Line
- Calcium channel α₂δ ligands
  - Gabapentin: number needed to treat (NNT) = 7 for significant pain improvement (4),(5)[A]
    - Dosing: up to 3,600 mg in 3 divided doses
Precautions: requires renal dosing
Common side effects: sedation, dizziness, peripheral edema, weight gain

Pregabalin NNT = 8 (6)[A]
  - Dosing: up to 600 mg in 2 doses
  - Precautions: requires renal dosing
  - Common side effects: sedation, dizziness, peripheral edema, weight gain
  - Gabapentinoid use questioned due to evidence limits and abuse potential, especially when prescribed with opioids.

Tricyclic antidepressants: NNT = 4 (6)[A]
  - Nortriptyline, desipramine, amitriptyline, clomipramine, imipramine
    - Dosing: Start 10 to 25 mg at bedtime and then increase by 10 to 25 mg every 4 to 7 days up to 150 mg/day to efficacy and side effects.
    - Precautions: cardiac disease, glaucoma, prostatic adenoma, seizure, tramadol use
    - Geriatric: falls; limit dose to <75 mg.
    - Common side effects: somnolence, weight gain, anticholinergic effects

Serotonin norepinephrine reuptake inhibitors (SNRIs): NNT = 6 (6)[A]
  - Duloxetine
    - Dosing: 20 mg once daily to 60 mg twice daily; effective doses 60 to 120 mg daily
    - Precautions: hepatic disorder, tramadol use, hypertension
    - Common side effect: nausea
  - Venlafaxine
    - Dosing: 37.5 mg to 225.0 mg daily
    - Effective doses: 150 to 225 mg daily
    - Precautions: cardiac disease, tramadol use, hypertension
    - Common side effects: nausea, hypertension at higher doses

Lidocaine, 5% patches (6)[B]
  - As effective as pregabalin for localized neuropathic pain from diabetes or herpes
  - Dosage: 1 to 3 patches for 12 hours daily to cover the painful area
  - Precautions: none
  - Common side effects: local erythema, itch, rash

Second Line
Capsaicin high-concentration patches (8%): NNT = 11 (6)[A]
- Dosing: 1 to 4 patches to cover the painful area; 30 minutes application to feet, 60 minutes application to remainder of body; avoid use on face; benefits for up to 3 months
- Precautions: caution in progressive neuropathy
- Common side effects: pain (initial increase), erythema, itching, rare hypertension
- No benefit from low concentration capsaicin cream

Third Line
- Opioids (including tramadol): no proven long-term benefit; utility for neuropathic pain questioned
  - Chronic opioids decrease number and sensitivity of μ-opioid receptors, increasing hyperalgesia (7).
  - Tests show chronic pain patients on chronic opioids have higher pain sensitivity.
- Botulinum toxin type A (6)[A]
  - Limited evidence for peripheral syndromes on pain, no quality of life improvement
Dosage: 50 to 200 units subcutaneously to the painful area; repeat every 3 months.
- Precautions: local infection
- Common side effects: pain at injection site, weakness

Cannabinoids (dronabinol and nabilone): low quality evidence (5)[A]
- NNT = 20 for 50% improvement in pain
- Number needed to harm (NNH) = 3 for adverse events
  - NNH = 10 for psychiatric adverse events
  - NNH = 25 for withdrawal due to adverse events

ISSUES FOR REFERRAL
- Physical or occupational therapy and psychology referrals part of standard multidisciplinary care
- Refer to pain clinic if refractory to initial treatment for trial of additional therapies.

ADDITIONAL THERAPIES
- Interventional pain management (epidural or peripheral nerve injections) will provide partial, lasting relief in 40–60% of patients (3)[B].
- Spinal cord stimulation (SCS): Pain that is continuous and unchanging responds best. Best evidence for failed back surgery syndrome with leg pain. Less common indications are peripheral nerve injury, CRPS, and painful peripheral neuropathy (3)[B].
- Peripheral nerve stimulation (PNS): Indications include pain in the distribution of an accessible peripheral nerve.
- Intrathecal drug delivery: reserved for refractory pain; ziconotide has demonstrated efficacy (3)[B].
- Transcutaneous electrical nerve stimulation is widely used; evidence of efficacy is poor (3).
- Ketamine infusions show limited short-term benefit in small trials.

SURGERY/OTHER PROCEDURES
Nerve destructive procedures haven’t shown effectiveness and may cause additional insult/injury (an exception is treatment of terminal cancer) (3)[B],(8).
- Sympathectomy dorsal root entry zone lesion (dorsal rhizotomy)
- Lateral cordotomy
- Trigeminal nerve ganglion ablation

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture: limited evidence for improvement in pain and quality of life, especially when combined with medication

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Multidisciplinary team
- Periodic evaluation to rule out other treatable conditions

Patient Monitoring
- Pain management requires ongoing evaluation, patient education, and reassurance.
- Patient compliance and adequacy of analgesic drug titrations should be continually evaluated
and documented, especially opioids.

**PROGNOSIS**
Chronic course of pain symptoms often requires management with numerous medications and adjunctive therapies. Complete pain relief is rare.

**COMPLICATIONS**
Long-term disability and drug addiction are possible.

**CLINICAL PEARLS**
Neuropathic pain is a common syndrome, affecting up to 10% of the population with major impacts on quality of life. Due to numerous mechanisms in neuropathy, potential benefit from any single treatment is limited. Narcotics likely to have more harm than benefit, and chronic narcotics likely increase pain. Functional goals and realistic pain targets are essential. Physical therapy, occupational therapy, and psychological treatment should be standard elements of multidisciplinary care.
NEUROPATHY, PERIPHERAL
Christine S. Persaud, MD, CAQSM • Kameron Bazmi, MD

BASICS

DESCRIPTION
- Peripheral neuropathy (PN) is a functional or structural disorder of the peripheral nervous system (PNS).
- PN affects any combination of motor, sensory, or autonomic nerves.
- The motor PNS comprises spinal cord motor neurons, their nerve roots that combine to form plexus, and branches that form individual nerves innervating skeletal muscles. Peripheral motor involvement causes muscle atrophy, weakness, cramps, and fasciculations.
- The sensory PNS consists of sensory organs, which transmit touch, vibration, and position sensation in large-diameter myelinated fibers; and pain and temperature in small-diameter, lightly myelinated and unmyelinated C fibers to the dorsal root ganglia. Sensory signals are relayed to the central nervous system (CNS) for integration. Disorders of sensory nerves produce negative phenomena (loss of sensibility, lack of balance) or heightened phenomena (tingling or pain). Large sensory fiber dysfunction impairs touch and vibration sensation, whereas small fiber sensory neuropathy (SFSN) affects pin and thermal sensation and causes neuropathic pain.
- The autonomic nervous system (ANS) includes the sympathetic and parasympathetic systems. ANS dysfunction causes cardiovascular, gastrointestinal, and sudomotor symptoms.
- The PNS can be affected from the cell body (sensory ganglionopathy or motor neuronopathy), root (radiculopathy), or plexus (plexopathy) to the nerve (demyelinating or axonal neuropathy).

EPIDEMIOLOGY

Prevalence
Approximately 2.4% of general population to an estimated 8% of people >55 years old are affected by distal symmetric PN. Diabetic sensorimotor polyneuropathy can affect 66% of type 1 diabetic and 59% of type 2 diabetic patients.

ETIOLOGY AND PATHOPHYSIOLOGY
- PN can be acquired or hereditary.
- The most common cause of acquired PN is diabetes mellitus.
- Other categories of acquired PN with illustrative examples are the following:
  - Vascular: ischemia, vasculitis
  - Infectious: HIV, hepatitis C, cryoglobulinemia, Lyme disease
  - Traumatic: compression, crush, or transection
  - Autoimmune: rheumatoid arthritis, Sjögren, postinfectious Guillain-Barré syndrome (GBS), chronic inflammatory demyelinating polyneuropathy (CIDP), sarcoidosis
  - Metabolic: diabetes, renal failure, hypothyroidism, vitamin B12 deficiency, celiac disease
  - Iatrogenic/toxic: chemotherapy, platinum, taxanes, metronidazole, colchicine, infliximab, alcoholism
  - Idiopathic: 30% of PN
– Neoplastic/paraneoplastic: paraproteinemia, Waldenström macroglobulinemia, multiple myeloma, amyloidosis, neurofibromatosis

- PN occurs due to demyelination or axonal degeneration.
- Demyelination results from Schwann cell dysfunction, mutations in myelin protein genes, or direct damage to myelin sheaths.
- Axonal degeneration occurs when injury/dysfunction occurs at the cell body or axon.

**Genetics**
- Approximately 50% of undiagnosed PN is hereditary.
- Currently, there are >70 known genetic causes of hereditary PN.
- Charcot-Marie-Tooth (CMT) neuropathies: the most common hereditary PN
  - CMT1A (duplication of the PMP22 gene) is the most common CMT.
  - A PMP22 deletion causes hereditary neuropathy with liability to pressure palsy (HNPP).

**RISK FACTORS**
Systemic disorders predispose to PN such as diabetes, alcoholism

**GENERAL PREVENTION**
- Healthy nutrition and avoidance of alcoholism and of pressure at nerve entrapment sites
- Surveillance for glucose dysmetabolism and tight glycemic control may prevent diabetic PN.

**DIAGNOSIS**

**HISTORY**
- A detailed inquiry for symptoms of sensory, motor, or autonomic dysfunction:
  - Numbness, tingling, prickling, burning pain, a “tightly wrapped” sensation, and an “unsteady gait”
  - Distal weakness manifests as foot drop (tripping, foot slapping) or difficulty with grip; proximal weakness (e.g., difficulty rising from a chair) is less common.
  - Orthostatic dizziness, abnormal sweating, constipation, or voiding difficulties
- Symptom onset:
  - Acute: Consider infection (e.g., Lyme disease), postinfectious dysimmune process (e.g., GBS), ischemia (e.g., vasculitis), toxin, or trauma.
  - Subacute: Consider metabolic, neoplastic, paraneoplastic, or dysimmune processes.
  - Chronic: Consider dysimmune process (CIDP), idiopathic, or hereditary.
- Progression: stable or indolent; slowly or rapidly progressive; monophasic or relapsing or remitting
- Anatomic pattern: focal, multifocal, diffuse

**PHYSICAL EXAM**
- Based on exam, a functional (sensory: small fiber vs. large fiber vs. mixed, sensorimotor, motor, autonomic) and anatomic (distal symmetric, multifocal, or focal) pattern of PN should be established.
- Cognition preserved in isolated PN
- Cranial nerves may be involved with focal or multifocal PN (e.g., bifacial weakness may occur with GBS, Lyme disease, and sarcoidosis, among other causes).
- Stocking-glove sensory loss is typical of distal symmetric sensory PN (e.g., diabetes).
● Isolated reduced pin or thermal sensation or allodynia suggests a pure SFN.
● Reduced vibration and proprioception suggests large-fiber sensory neuropathy; when severe, a Romberg sign is present, and gait is wide based or ataxic.
● Distal muscle atrophy and weaknesses of toe extension and finger abduction are often present with distal symmetric axonal PN.
● In acquired demyelinating PN (e.g., GBS or CIDP), weakness is commonly both proximal and distal.
● Deep tendon reflexes may be reduced or absent, distally at the ankles in large-fiber axonal PN, or diffusely in demyelinating PN.
● High arched or flat feet or hammer toes suggest hereditary PN.

**ALERT**

- Hemibody deficits or sensory loss below a spinal cord level suggests a CNS process.
- Hyperreflexia and spasticity are upper motor neuron signs not seen with isolated PN.

**DIFFERENTIAL DIAGNOSIS**

The following categories of PN can be identified (differential diagnosis [DDx] listed when applicable):

- Pure sensory neuropathy
  - DDx: SFN, sensory ganglionopathy, polyradiculopathy
- Distal symmetric sensorimotor axonal PN
  - Most common type of PN
  - DDx: distal acquired demyelinating symmetric (DADS) PN
- Motor predominant PN
  - DDx: motor neuron disease, polyradiculopathy, immune-mediated multifocal motor neuropathy (MMN)
- Mononeuropathy
  - Most likely due to compression, entrapment, or trauma
  - DDx: monoradiculopathy
- Mononeuropathy multiplex
  - DDx: plexopathy, polyradiculopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Blood tests
  - CBC, BUN, Cr, FBG, HbA1C, vitamin B\textsubscript{12} with methylmalonic acid, LFTs, serum protein immunofixation electrophoresis (SPIEP), TSH
- Nerve conduction studies and electromyography (NCS/EMG)
  - Delineate axonal versus demyelinating, anatomic pattern, chronicity, and severity of PN
- Test of small nerve fiber function
  - Autonomic reflex screen, testing of sweat function, quantitative sensory testing, epidermal skin biopsy
- Specialized epidermal skin biopsy
  - In clinically suspected SFN if NCS/EMG is normal
  - Analysis of lower limb epidermal nerve fiber density (ENFD) (1)[A]
- Neuroimaging
  - Generally not indicated in evaluation of PN but useful in evaluation of brachial
plexopathies, radiculopathies, or where findings are attributable to the CNS

**Follow-Up Tests & Special Considerations**
- Additional blood tests are done based on the medical history, the PN type, and NCS/EMG findings.
- For example: vitamin A, vitamin D, vitamin E, zinc, copper, ESR, CRP, ANA, Hep B/C, antitissue transglutaminase
- Genetic testing for diagnosis of hereditary PN should be ordered by neurologists with expertise in PN.
- Screen patients with distal symmetric PN for unhealthy alcohol use with CAGE-AID or AUDIT-C.

**ALERT**
Ordering of laboratory batteries (e.g., peripheral nerve antibody panels) without careful consideration of the clinical and NCS/EMG features should be avoided.

**Diagnostic Procedures/Other**
- Nerve biopsy (sural or superficial peroneal nerve): useful if vasculitis, amyloidosis, granulomatous disorders, or neoplastic infiltration is suspected; rarely helpful in late-onset chronic, slowly progressive distal symmetric PN
- Lumbar puncture
  - Cytoalbuminologic dissociation in GBS or CIDP
  - Infection, inflammation, or neoplasia in polyradiculopathies

**Test Interpretation**
- Demyelinating PN: disproportionate slowing of conduction velocities or prolonged distal latencies on NCS
- Axonal PN: reduced amplitude in sensory or motor responses, with relatively preserved conduction velocities on NCS
- Reduced ENFD on distal leg skin biopsies is supportive of SFN.

**TREATMENT**

**GENERAL MEASURES**
- Counsel on foot care and properly fitted footwear.
- Monitor feet for early signs of ulcer and injury.
- Targeted treatment for underlying systemic conditions:
  - Glycemic control, thyroid hormone supplementation, vitamin supplementation, antimicrobial therapy (e.g., Lyme disease, HIV), glucocorticoids for sarcoidosis, and cytotoxic therapy for vasculitis

**MEDICATION**

**First Line**
Treatment of neuropathic pain: evidence of efficacy derived from clinical trials in diabetic painful neuropathy (DPN), postherpetic neuralgia (PHN), or trigeminal neuralgia:
- Anticonvulsants: gabapentin, for PHN; pregabalin, for DPN and PHN; gabapentin (off-label), for DPN; oxcarbazepine, for DPN, carbamazepine, for trigeminal neuralgia
SNRI: duloxetine or venlafaxine for DPN
Tricyclic antidepressants (TCA): amitriptyline or nortriptyline
Patches: lidocaine 5%, capsaicin 8%
Supplements: α-lipoic acid, acetyl-L-carnitine

**Second Line**
- Mexiletine
- Tramadol: off-label for DPN; tapentadol: for DPN

**Third Line**
- Tapentadol: for DPN

**ISSUES FOR REFERRAL**
- Rapidly progressive symptoms, suspected demyelinating PN, or hereditary PN should be referred to a neurologist with expertise in neuromuscular disorders.
- Patients with vasculitic PN should be referred to rheumatology.
- Patients with progressive painful PN, dysautonomia, and/or cardiomyopathy should be evaluated for transthyretin (TTR)-related familial amyloidosis.
- Patients with paraproteinemia should have a skeletal bone survey and be referred to hematology.
- Patients with imbalance, ataxia, or falls should be referred to a physiatrist for management and to physical therapy for gait and balance training.

**ADDITIONAL THERAPIES**
- Combination therapy (e.g., gabapentin with TCA or venlafaxine or tramadol) can be more effective than monotherapy for neuropathic pain.
- Botulinum toxin subcutaneous, intradermal, or direct nerve injections can be considered for trigeminal neuralgia, DPN, or CRPS (2)[A].
- Long-acting opiates can be considered for refractory neuropathic pain.
- Additional immunosuppressant agents (e.g., cyclophosphamide) may be used in refractory chronic dysimmune PN.
- Immunotherapy for dysimmune PN
  - Intravenous immunoglobulin (IVIG): within the first 2 weeks of GBS to hasten recovery (3)[A]; as a first-line alternative to corticosteroids for treatment of CIDP (4)[A]; and for prevention of secondary axonal loss in MMN (5)[A]
    - Loading dose 2 g/kg body weight divided into 2 to 5 days; maintenance regimen variable for CIDP and MMN
    - Adverse effects (AE): headache, fever, hypertension, and rarely pulmonary embolism
  - Plasma exchange: first agent shown to improve functional outcome for patients with GBS (6)[A]; short-term benefit in CIDP (6)[A]
    - AE: catheter complication, hypotension, and others
  - Corticosteroids: a first-line option in treatment of CIDP (6)[C]; oral or pulsed IV regimen can induce remission.
- Treatment of autonomic symptoms
  - Compression stockings, hydration, midodrine, and fludrocortisone for orthostatic hypotension
  - Pyridostigmine for immune-mediated dysautonomia (off-label)
ALERT
Opiates have significant side effects and may cause rebound headaches, tolerance, and dependence.

SURGERY/OTHER PROCEDURES
- Decompressive surgery for entrapment neuropathy (e.g., carpal tunnel syndrome)
- Foot and ankle surgery to improve symptoms or function in hereditary PN
- Radiation, surgery, or bone marrow transplantation for plasmacytoma or osteosclerotic myeloma or POEMS syndrome
- Liver transplantation for amyloidotic PN

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Low-intensity transcutaneous electrical nerve stimulation (TENS), acupuncture, meditation, supplements (G-agmatine, methylcobalamin, inositol)
- Herbal supplementation such as nutmeg or St. John’s wort have not been shown to be beneficial.

ALERT
Vitamin B₆ supplementation may cause peripheral neurotoxicity and should be avoided except for a deficiency state.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Patients with suspected GBS should be admitted for diagnosis, monitoring (30–60% may develop cardiovascular or respiratory failure), and acute treatment.
- Elective intubation may be required in GBS when forced vital capacity is <15 mL/kg body weight.
- Other rapidly progressive undiagnosed PNs that impair independent ambulation may require admission.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Physical therapy and gait assistive devices as needed.
- Strengthening exercises improved muscle strength, which may assist in function.
- Flu vaccination should be avoided in the 1st year following GBS.

PROGNOSIS
- Late-onset idiopathic distal symmetric axonal PNs are indolent.
- 80% of GBS have a near complete or good recovery. 80% of CIDP have moderate or good response with treatment but can be relapsing.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- G62.9 Polyneuropathy, unspecified
- G60.9 Hereditary and idiopathic neuropathy, unspecified
- G60.8 Other hereditary and idiopathic neuropathies

CLINICAL PEARLS

- There are many causes of PN. Diagnosis is made by history and physical exam, targeted laboratory testing, NCS/EMG, skin biopsy, or ANS testing.
- Consider hereditary neuropathy if patient has an early age of PN symptom onset, family history of PN, or foot deformity.
- GBS is monophasic and progresses for up to 4 weeks; CIDP progresses beyond 8 weeks and, if untreated, usually has a progressive course.
NICOTINE ADDICTION
Kamala M. Nyamathi, MD • Benjamin N. Schneider, MD

BASICS

DESCRIPTION
The compulsive use of nicotine products coupled with a lack of control over using, withdrawal symptoms, and/or continued use despite knowledge of or experiencing adverse consequences.

EPIDEMIOLOGY

Prevalence
Approximately 38 million people in the United States ≥18 years of age are current tobacco users. In the past year, 58.7 million individuals smoked cigarettes, 13.3 million smoked cigars, 2.1 million smoked pipes, and 8.6 million used smokeless tobacco. An estimated 3 million middle and high school students use at least one tobacco product, and about 80% of these individuals will continue smoking into adulthood. E-cigarette use among youth has increased 10-fold for high school and middle school students from 2011 to 2015 and has been associated with nicotine addiction in adulthood.

Cost and Impact
Nearly 500,000 Americans die prematurely each year from smoking, including 41,000 deaths from secondhand smoke exposure. The estimated economic costs attributable to smoking approach $300 billion annually, with direct medical costs of at least $130 billion. Life expectancy of smokers is, on average, 10 to 12 years shorter than nonsmokers.

ETIOLOGY AND PATHOPHYSIOLOGY

- Similar to other addictive drugs, nicotine affects neural pathways that control reward and pleasure.
- Nicotine exerts its biologic effects through nicotinic acetylcholine receptors (nAChRs), which modulate neurotransmission with acetylcholine and other chemical messengers including glutamate, GABA, dopamine, serotonin, acetylcholine, and norepinephrine. In this way, it induces euphoria, assists in information processing, reduces anxiety, and mitigates fatigue.
- Upregulation of these receptors occurs over time, leading to tolerance and dependence.
- Polymorphisms in neuronal nAChR genes are associated with increased susceptibility to dependence.
- Nicotine is metabolized by cytochrome P450 2A6 (CYP2A6). Individuals who are fast metabolizers tend to smoke more cigarettes, are more likely to suffer intense withdrawal symptoms, and have a lower probability of quitting than slow metabolizers.
- Nicotine withdrawal involves the release of corticotropin-releasing factor in the amygdala, which induces the perception of anxiety and stress.

Pregnancy Considerations
- Smoking is a risk factor associated with placenta previa, abruptio placentae, decreased maternal thyroid function, preterm premature rupture of membranes, and ectopic pregnancy.
- Carbon monoxide and nicotine interfere with fetal oxygen supply, resulting in decreased birth weights and intrauterine growth restriction.
Maternal smoking adversely affects fetal lung development, with lifelong decreases in pulmonary function and increased risk of asthma. Maternal smoking is associated with increased risk for sudden infant death syndrome, learning and behavioral problems, and obesity.

**RISK FACTORS**
- Mental illness (depression, posttraumatic stress disorder, bipolar disorder, and schizophrenia)
- Low socioeconomic status
- Low educational status
- Early firsthand nicotine experience
- Concurrent substance abuse
- Home and peer influence

**GENERAL PREVENTION**
- The U.S. Preventive Services Task Force (USPSTF) strongly recommends (1)[A]:
  - Screening all adults for tobacco use, providing cessation interventions for those who screen positive
  - Screening all pregnant women for tobacco use and providing pregnancy-tailored counseling to those who screen positive (1)
- The USPSTF recommends that clinicians provide interventions, including education or brief counseling to prevent initiation of tobacco use among school-age children and adolescents (1)[B].

**DIAGNOSIS**

**HISTORY**
- Identify types, amount, and duration of nicotine products used.
- Review previous attempts to quit (methods used and duration of cessation).

**PHYSICAL EXAM**
- Pulmonary exam: wheezing, decreased breath sounds, prolonged expiration
- Cardiovascular exam: tachycardia, hypertension
- HEENT exam: epithelial dysplasia, squamous cell carcinoma, leukoplakia, stained teeth, hoarseness

**DIAGNOSTIC TESTS & INTERPRETATION**
- Lung cancer screening with low-dose CT is recommended annually by USPSTF for patients between 55 and 80 years old with a history of 30+ pack years of tobacco use who are currently smoking or have quit within the past 15 years (except those with life-limiting comorbidities).
- Neither spirometry nor regular chest x-rays are recommended for routine screening.

**TREATMENT**
- Counseling (2)[A]
  - Counseling interventions (individual, telephone, or group) improve quit rates compared to minimal support (relative risk [RR] of 1.76 [95% CI 1.58–1.96]) (1).
Combined behavioral and pharmaceutical interventions increased cessation (RR, 1.82 [95% CI 1.66–2.00]) (1).

More intensive interactions (i.e., motivational interviewing, close follow-up) may result in higher rates of quitting.

**Brief strategies to help the patient willing to quit tobacco use—the “5 As”** (2)[A]
- Ask patient if he or she uses nicotine.
- Advise him or her to quit.
- Assess willingness to make a quit attempt.
- Assist those willing to make a quit attempt.
- Arrange follow-up contact to prevent relapse.

**Enhancing motivation to quit: the “5 Rs”** (2)[A]
- Relevance: Encourage patient to indicate why quitting is personally relevant.
- Risks: Ask patient to identify potential negative consequences of use.
- Rewards: Ask patient to identify potential benefits of cessation.
- Roadblocks: Ask patient to identify barriers to quitting and provide treatment (e.g., problem-solving counseling or medication) that could address barriers.
- Repetition: Repeat motivational intervention each visit.

Users should be given a choice of methods to quit.

Quit rates appear to be higher with abrupt quitting rather than gradual reduction prior to the quit date (49% vs. 39% at 4 weeks and 22% vs. 15% at 6 months). Over 4 weeks, there was no significant difference between groups in withdrawal symptoms or urge intensity, both of which declined over time (3)[B].

**MEDICATION**

There are currently seven FDA-approved medications: nicotine replacement therapy (NRT), both long-acting (i.e., patch) and short-acting (i.e., gum, inhaler, lozenge, nasal spray) types, and non-NRT meds, bupropion SR and varenicline.

With few exceptions, the choice of a first-line medication depends on patient preference.

NRT (RR, 1.60 [95% CI 1.53–1.68]) (1)[A] (Gum: pregnancy Category C. All other formulations are Category D.)

- **Patch**: For <10 cigarettes per day or <2 cans per pouches of smokeless tobacco, start with 14 mg/day for 6 weeks and then 7 mg/day for 2 weeks; for 10 to 29 cigarettes per day or 2 to 3 cans per pouches of tobacco, start 21 mg/day for 6 weeks, then 14 mg/day for 2 weeks, and then 7 mg/day for 2 weeks; for 30 to 39 cigarettes per day or 3+ pouches per cans of tobacco, start 35 mg (21 mg/day + 14 mg/day patch) for 4 weeks and then 21 mg/day for 2 weeks, 14 mg/day for 2 weeks, 7 mg/day for 2 weeks; for 40+ cigarettes per day, start 42 mg (21 mg/day patch for 2 weeks) for 4 weeks and then 21 mg/day for 2 weeks, 14 mg/day for 2 weeks, 7 mg/day for 2 weeks. Extending use of the patch beyond 8 to 10 weeks may improve abstinence rates.

- **Gum**: For >25 cigarettes per day, start 4 mg gum q1–2h for 6 weeks; for <25 cigarettes per day, start 2 mg gum q1–2h for 6 weeks; then double dosing interval every 3 weeks (i.e., q2–4h and then q4–8h). Chew then tuck between cheek and gingiva once nicotine flavor is released, repeat for up to 30 minutes and then discard. Avoid using with acidic foods (i.e., coffee, soda), which decrease nicotine absorption.

- **Lozenges**: For patients who smoke their first cigarette within 30 minutes of waking, start 4 mg lozenge PO q1–2h for 6 weeks; if first cigarette >30 minutes after waking, start 2 mg lozenge PO q1–2h for 6 weeks; then double dosing interval every 3 weeks (i.e., q2–4h and...
then q4–8h).

- Nasal spray: Start 1 to 2 sprays (0.5 mg per spray) each nostril q1h for 8 weeks and then taper; max 10 sprays per hour and 80 sprays per day
- Inhaler: 6 to 16 cartridges inhaled (4 mg per cartridge) per day for 6 to 12 weeks and then taper; incorporates the behavioral and sensory aspects of smoking

- Combination NRT: All forms of NRT increase quit rate 50–70% (4)[A]. Combining long-acting maintenance with short-acting breakthrough NRTs is more effective than using any single method alone. If combining patch with lozenge or gum, limit to 1–3 two mg. Avoid combined NRT use for patients with serious arrhythmias, unstable angina, MI within the prior 2 weeks, or those age <18 years old.
- Bupropion SR (RR, 1.62 [95% CI 1.49–1.76]) (1)[A] is an atypical antidepressant and norepinephrine-dopamine reuptake inhibitor (pregnancy Category C). Contraindications: history of seizure, stroke, brain injury, brain tumors, anorexia/bulimia, recent use of MAOI (within 14 days)
  - Start 1 week before target quit date due to time needed to reach steady state.
  - Use 150 mg/day for 3 days and then 150 mg BID for 7 to 12 weeks.
- Varenicline (RR, 2.27 [95% CI 2.02–2.55]) is a nicotinic acetylcholine partial agonist (pregnancy Category C) (1)[A]. Contraindications: known history of skin reactions or hypersensitivity. Associated neuropsychiatric symptoms may include vivid dreams, sleepwalking, depression, suicidal ideation/attempts in patients with and without preexisting psychiatric conditions—close monitoring recommended.
  - Starter pack: 0.5 mg/day for 3 days, 0.5 mg BID for 4 days, 1 mg/day starting day 7
  - Maintenance pack of 1 mg BID for 12 weeks; if successful, may continue for another 12 weeks.
- Varenicline + bupropion is not more effective than either alone and confers increased side effects.
- Varenicline + NRT is more effective at 6 months than varenicline alone (NNT 6).
- Nortriptyline (off-label use) is a tricyclic antidepressant (pregnancy Category D). Contraindications: narrow-angle glaucoma, heart disease (CAD, heart block, long QT)
  - Start 25 mg/day, gradually increase to 75 to 100 mg/day and continue for 12 weeks.
  - Set quit date 2 to 4 weeks after initiation.
- E-cigarette is an electronic device that delivers aerosolized liquid with or without nicotine and includes various flavorings and other chemicals. Insufficient evidence exists regarding this product’s safety and efficacy. Low-quality evidence suggests that e-cigarettes can help patients cut down on the number of cigarettes smoked but not nicotine consumption. Other research demonstrates poor efficacy of abstinence with long-term follow-up. Long-term safety has not been established (5).

**Pregnancy Considerations**

- Tobacco cessation prior to 15 weeks’ gestation provides the greatest benefit for both the woman and fetus, but quitting any time is beneficial.
- ACOG recommends that pregnant and breastfeeding women be offered behavioral therapy and education as first-line treatment. NRT and medications should be reserved for patients in need of additional assistance given limited safety data.
- NRT is metabolized faster in pregnant women, which may lead to higher dose requirements.

**Pediatric Considerations**
Behavioral therapy (including CBT) is recommended as first-line treatment. There is evidence that group counseling is superior to individual counseling and group messaging for tobacco cessation in youth (RR, 1.35 [95% CI 1.03–1.77]) (6)[A].

There are currently no FDA-approved pharmacologic treatments for youth.

AAP recommends using NRT only for youth with moderate to severe substance use disorder.

Risk of long-term addiction is much higher when smoking is initiated in adolescence than later in life, likely reflecting changes induced by nicotine in the developing brain. The biology of addiction, including withdrawal, occurs with fewer daily cigarettes in teens than in adults. Explanation of these biologic factors may help adolescents to stop or defer smoking.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture: no consistent evidence of efficacy

Hypnotherapy: no consistent evidence of efficacy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Consider NRT for inpatients who use nicotine to decrease withdrawal symptoms (use with caution in patients with unstable angina, serious arrhythmias, or MI within the previous 2 weeks).

Bupropion may not adequately control acute withdrawal symptoms.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients who have initiated therapy should follow up after 1 to 2 weeks to monitor response and side effects.

Monitor for signs of nicotine withdrawal syndrome and start medication-assisted treatment or adjust dosage:

- Increased appetite/weight gain (4 to 5 kg over 10 years)
- Dysphoric, depressed mood, or anhedonia
- Insomnia
- Irritability, frustration, or anger
- Anxiety
- Difficulty concentrating
- Restlessness

Follow-up should continue periodically in person or via telephone, especially during the first 3 months.

Pharmacotherapy is generally recommended for 2 to 3 months duration.

PATIENT EDUCATION

http://smokefree.gov
http://women.smokefree.gov/
http://teen.smokefree.gov
http://www.nicotine-anonymous.org
http://quitnet.meyouhealth.com
1-800-QUIT-NOW (1-800-784-8669)

PROGNOSIS
Roughly 50% of all smokers will die from a tobacco-related illness. Former smokers have a 50% reduction in risk of CAD 1 year after quitting, a 50% reduction in head and neck cancers by 2 to 5 years, and a 50% reduction in lung cancer mortality by 10 years. The risk of stroke is reduced to that of nonsmokers 2 to 5 years after quitting. 22% of smokers relapse within 3 months of quitting. Multiple attempts are often required. Approximately 50% of women who quit smoking in pregnancy resume smoking by 6 months postpartum. Individuals receiving support from significant others are more likely to quit.

**COMPLICATIONS**
- Chronic obstructive pulmonary disease (COPD) (emphysema and chronic bronchitis)
- Cancers (i.e., lung, oral/pharyngeal, kidney, bladder, cervical, anal, squamous cell)
- Atherosclerotic disease
- Insulin resistance
- Periodontal disease
- Osteoporosis and hip fracture (in women)
- Peptic ulcer disease
- Delayed wound healing
- Pregnancy and neonatal complications (discussed elsewhere)

cessation.org/resources/tools.html#clinicians

CODES

ICD10
- F17.200 Nicotine dependence, unspecified, uncomplicated
- F17.201 Nicotine dependence, unspecified, in remission
- F17.203 Nicotine dependence unspecified, with withdrawal

CLINICAL PEARLS
- Nicotine dependence is a chronic disease and will often require repeated interventions and multiple cessation attempts.
- Follow-up is key to continuing engagement and providing additional support as needed.
- Treatments, including but not limited to medications, can significantly increase rates of long-term abstinence.
- No single type of medication is best; thus, the choice should be based on patient preference and risk factors for side effects.
- Provide anticipatory guidance in adolescence.
NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)
Daniel T. Lee, MD, MA • Anita Wong, MD

BASICS

- A spectrum of fatty liver diseases not due to excess alcohol consumption ranging from nonalcoholic fatty liver (NAFL), to nonalcoholic steatohepatitis (NASH), to cirrhosis with hepatocyte injury with/without fibrosis
- Leading cause of chronic liver disease; implicated in up to 90% of patients with asymptomatic, mild aminotransferase elevation not caused by alcohol, viral hepatitis, or medications

DESCRIPTION

- NAFL (1)
  - Reversible condition in which large vacuoles of triglyceride fat accumulate in hepatocytes
  - Liver biopsy: fatty deposits in >5% of cells without hepatocellular injury (no hepatocyte ballooning, no necrosis, no fibrosis)
  - Alanine aminotransferase/aspartate aminotransferase (ALT/AST) enzymes usually normal but may be elevated, rarely >3 to 4 times upper limit normal (ULN)
  - Minimal risk of progressing to cirrhosis or liver failure
  - Synonym: steatosis
- NASH: progressive form of NAFL (1)
  - Liver biopsy: fatty deposits in >5% of cells with hepatocellular injury (ballooning, acute/chronic inflammation, ± fibrosis)
  - ALT and AST elevated, generally <3 to 4 times ULN
  - 30% with NASH may progress to fibrosis over 5 years, may progress to cirrhosis, liver failure, and rarely hepatocellular cancer
- NASH cirrhosis
  - Presence of cirrhosis with current or previous histologic evidence of steatosis or steatohepatitis

EPIDEMIOLOGY

- Nonalcoholic fatty liver disease (NAFLD): most common chronic liver disease in industrialized Western countries; usually benign, asymptomatic
- Predicted to become the most frequent indication for liver transplantation by 2030 (2)
- NASH may be symptomatic with progressive inflammation and fibrosis.
  - Predominant age: 40s to 50s; can occur in children
  - Predominant sex: male > female (slight)

Incidence

Estimates vary widely from 31 to 86 cases of NAFLD per 10,000 person-years to 29/100,000 person-years (1).

Prevalence

- United States estimate: 10–40%
- Worldwide: 6–33%, median 25% (1)
- Present in 58–74% of obese persons (BMI >30) and 90% of morbidly obese persons (BMI
Among individuals with type 2 diabetes mellitus, rate of 69–87%; in patients with dyslipidemia, rate of 50% (1)

ETIOLOGY AND PATHOPHYSIOLOGY
Primary mechanism is thought to be insulin resistance, leading to increased lipolysis, triglyceride synthesis, and increased hepatic uptake of fatty acids.

- NAFLD: excessive triglyceride accumulation in the liver and impaired ability to remove fatty acids
- NASH: multiple hit theory that inflammation precedes steatosis in environmentally and genetically predisposed people. Multiple insults, including insulin resistance, hormones from adipose tissue, nutritional factors, endotoxins released by the gut microbiota, oxidative stress damage, and genetic factors. These “hits” act on liver parenchymal cells via toll-like receptors to lead to the progression of NASH (3).

Genetics
Largely unknown: Some familial clustering and increased heritability. NAFL: more first-degree relatives with cirrhosis than matched controls; NASH: 18% with affected first-degree relative. Carriers of hemochromatosis gene are more likely to be affected. Patatin-like phospholipase (PNPLA3) polymorphism implicated in NAFLD, hypertriglyceridemia, and insulin resistance (1,2).

RISK FACTORS
- Obesity (BMI >30), visceral obesity (waist circumference >102 cm for men or >88 cm for women), hypertension, dyslipidemia, high serum triglycerides and low serum high-density lipoprotein (HDL) levels, metabolic syndrome
- Type 2 diabetes mellitus, cardiovascular disease, and chronic kidney disease (2)
- Possible associations with hypothyroidism, hypopituitarism, hypogonadism, obstructive sleep apnea, pancreaticoduodenal resection, osteoporosis, psoriasis, and polycystic ovary syndrome (2)
- Increasing age associated with increased prevalence, severity, advanced fibrosis, and mortality
- High fructose intake linked to intestinal dysbiosis and metabolic stress (4)
- Protein–calorie malnutrition; total parenteral nutrition (TPN) >6 weeks
- Severe weight loss (starvation, bariatric surgery)
- Organic solvent exposure (e.g., chlorinated hydrocarbons, toluene); vinyl chloride; hypoglycin A
- Gene for hemochromatosis/other conditions with increased iron stores
- Smoking
- Drugs: tetracycline, glucocorticoids, tamoxifen, methotrexate, amiodarone, antiretroviral agents for HIV, valproic acid, fialuridine, many chemotherapy regimens, and nucleoside analogues

Pregnancy Considerations
Acute fatty liver of pregnancy: rare but serious complication in 3rd trimester. 50% of cases are associated with preeclampsia.

- Symptoms: nausea, vomiting, headache, fatigue, right upper quadrant or epigastric pain, jaundice
- Elevated ALT and AST >300 IU/L but usually <1,000 IU/L; elevated bilirubin
Liver biopsy confirms diagnosis (do not delay treatment for biopsy).
Early recognition and prompt delivery is key.
Recurrence is rare.

**Pediatric Considerations**
- Pediatric NAFLD
  - Increasing prevalence of NAFLD among children. Parallels rise in pediatric obesity, with prevalence of 9.6% (1).
  - Reports of NAFLD as early as age 2 years and NASH-related cirrhosis as early as age 8 years.
  - Treat with intensive lifestyle modification.
  - Vitamin E of possible benefit.
- Reye syndrome: fatty liver syndrome with encephalopathy usually following viral illness
  - Symptoms
    - Vomiting with dehydration
    - Confusion, progressive CNS damage
    - Hepatomegaly with extensive fatty vacuolization
    - Hypoglycemia
  - Etiology unknown; viral URIs and drugs (especially salicylates) have been implicated; mortality rate: 50%
  - Treat with mannitol, IV glucose, and FFP.

**GENERAL PREVENTION**
- Avoid excess alcohol: ≤2 units per day (men); ≤1 unit per day (women)
- Maintain appropriate BMI
- Prevention and optimal management of diabetes
- Avoid hepatotoxic medications
- HAV and HBV vaccination if not immune
- Pneumococcal and annual influenza vaccinations

**COMMONLY ASSOCIATED CONDITIONS**
Central obesity, hypertension, type 2 diabetes, insulin resistance, hyperlipidemia, preeclampsia in pregnancy, CVD and arrhythmias, hypothyroidism, hypogonadism, OSA (1,2)

**DIAGNOSIS**
- Routine screening not recommended.
- Consider NAFLD in patients with asymptomatic aminotransferase elevations (1)[A].
- Can occur with normal AST/ALT levels (1)[A]
- NAFLD has no distinguishing historical/lab features to distinguish from other chronic liver disorders.
- Index of suspicion is higher with risk factors such as metabolic syndrome, insulin resistance, or obesity.
- May present as cryptogenic cirrhosis
- Noninvasive biomarkers of steatosis/fibrosis are not sufficiently reliable; no validated test yet available.
- Liver biopsy is the definitive diagnostic test but should only be considered if results will
HISTORY
- Typically asymptomatic
- Possible fatigue and/or abdominal fullness
- Vague right upper quadrant pain
- History of medications, alcohol use, family history

PHYSICAL EXAM
Most common signs (all are infrequent)
- Liver tenderness
- Mild to marked hepatomegaly
- Splenomegaly
- In advanced cases: cutaneous stigmata of chronic liver disease or portal hypertension (e.g., palmar erythema, spider angioma, ascites)

DIFFERENTIAL DIAGNOSIS
- Viral hepatitis
- Alcoholic fatty liver
- Drug- or toxin-induced hepatitis
- Metabolic liver disease
- Autoimmune hepatitis
- Celiac disease
- Muscle disease, if nonhepatic cause of elevated enzymes is possible

DIAGNOSTIC TESTS & INTERPRETATION
The diagnosis of NAFLD requires that there is hepatic steatosis (imaging or biopsy); no history of significant alcohol consumption; no other identifiable causes and no co-existing liver disease.

Initial Tests (lab, imaging)
- ALT and AST may be elevated.
  - Nonalcoholic, usually AST/ALT >1
  - If alcohol induced, usually AST/ALT ≥2
  - Nonspecific enzyme abnormalities may exist or may be normal with advanced cirrhosis (1,3).
- Level of enzyme elevation does NOT correlate with degree of fibrosis (1).
- Serum ferritin (1.5 times normal), alkaline phosphatase (2 to 3 times normal), and total/direct bilirubin may be elevated (1).
- Severity and chronicity are characterized by defects in ability to produce plasma proteins (serum albumin, PT) and thrombocytopenia—marker for cirrhosis (1).
- Lipids abnormalities are common and include elevated cholesterol, low-density lipoprotein (LDL), and triglyceride and decreased HDL (1).
- Biomarkers of inflammation, increased oxidative stress, or hepatocyte apoptosis such as leptin, adiponectin, CRP, serum caspase, and cytokeratin 18 may help differentiate NASH from NAFLD (1)[B].
- Serologic studies to exclude other causes of liver disease (celiac, α1-antitrypsin, iron, copper, Hepatitis A IgG, Hepatitis B Surface Antigen (HBsAg), Hepatitis B Surface Antibody, Hepatitis B core Antibody, Hepatitis C Antibody, anti-smooth muscle antibody, ANA, serum
gammaglobulin) (1)[B]

- Ultrasound (US) is first-line imaging modality for assessing liver chemistry abnormalities: Fatty liver is hyperechoic on US. MRI/CT may also be used; NAFLD has decreased hepatic attenuation on CT (1)[B].

### Follow-Up Tests & Special Considerations
- Other modalities can help noninvasively quantify fibrosis by estimating liver stiffness (1).
  - Clinical decision aids: NAFLD fibrosis score, FIB-4 index, APRI score
  - Serum biomarkers: Enhanced Liver Fibrosis panel, Fibrotest, Hepascore
  - Imaging: vibration controlled transient elastography (VCTE) or FibroScan, acoustic radiation force impulse (ARFI), magnetic resonance elastography (MRE) (5)[B]
- No modality has been found to accurately distinguish and diagnose simple steatosis from steatohepatitis (5)[B].

### Diagnostic Procedures/Other
Liver biopsy is the gold standard for diagnosis and prognosis—must have likelihood of changing management prior to biopsy (1)[B].

### Test Interpretation
- The NAFLD activity score (NAS) is used to grade diagnosis, based on three histologic features: steatosis (0 to 3), inflammation (0 to 3), and hepatocyte ballooning (0 to 2), for score between 0 and 8. NASH is very likely with scores ≥5 (3).
- Staging scale (0 to 4) is based on fibrosis (1,3).

### TREATMENT
- Sustained weight loss (3–5% body weight) through lifestyle modification is most successful treatment (1,6)[A]. Weight loss for those who are overweight or obese is the only therapy that has good evidence of benefits and safety.
- Bariatric surgery not proven to improve NASH (1)[B]
- Aerobic exercise 3 to 5 times per week for 20 to 45 minutes with reduced calorie intake/diet modifications (1)[B]
- Tight diabetes control (1,6)[B]
- Treatment of metabolic syndrome—hypertension, dyslipidemia, and obesity (1,6)[B]
- Avoid or limit alcohol consumption (6)[A].
- Avoid hepatotoxic medications (1)[B].

### MEDICATION
- Currently no effective medication treatment (1,6)[A]
- Some promising agents include the following:
  - Thiazolidinediones (pioglitazone): improves liver histology, only use with biopsy-proven NASH (1)[B]
  - Vitamin E 400-800 IU daily: long-term safety concerns at high doses; only use with biopsy-proven NASH (1)[C]
  - GLP-1 receptor agonists, exenatide and liraglutide
  - Pentoxifylline
  - Agents targeting apoptosis, fibrosis, and the gut microbiome are in early trials
Agents that have not shown benefit:
- Metformin
- Ursodeoxycholic acid
- Statins
- Probiotics
- Obeticholic acid (bile acid derivative)

ISSUES FOR REFERRAL
Patients with persistent AST/ALT elevations 2 to 3 times ULN or fibrosis on biopsy benefit from hepatology consult (1)[A].

SURGERY/OTHER PROCEDURES
Bariatric procedures: NAFLD is not a contraindication in otherwise eligible obese patients. There is a lack of data to definitively assess benefits and harms of surgery in treating patients with NASH (1)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Annual monitoring of LFTs (1,6)[B]
- Consider surveillance with US or CT scan to evaluate for disease progression (6)[B]. Improvements provide motivation for lifestyle changes.
- Routine liver biopsy is not recommended but may be repeated 5 years after baseline biopsy if progression of fibrosis is suspected (1,6)[B].
- Hepatic fibrosis staging is the strongest predictor for all-cause and disease-specific mortality in patients with histologically confirmed NAFLD (2)[B].

DIET
Low in saturated and trans fat; low in simple carbohydrates; avoid excessive alcohol (protective or worsening effect of light/moderate consumption inconclusive).

PATIENT EDUCATION
Extensive counseling on sustained lifestyle changes in nutrition, exercise, and alcohol use.

PROGNOSIS
Within the spectrum of NAFLD, only NASH has been shown to be progressive, potentially leading to cirrhosis, hepatocellular carcinoma, cholangiocarcinoma, and/or liver failure:
- Cirrhosis develops in up to 20% of patients but may not always be present. Up to 42% of patients develop HCC without showing cirrhosis (3).
- Transplantation is effective, but NASH may recur after transplantation due to ongoing risk factors.

COMPLICATIONS
Progressive disease may lead to decompensated cirrhosis and portal hypertension with complications such as ascites, encephalopathy, bleeding varices, and hepatorenal or hepatopulmonary syndromes.

Alcohol Use Disorder (AUD); Cirrhosis of the Liver; Diabetes Mellitus, Type 2; Metabolic Syndrome

CODES

ICD10
K76.0 Fatty (change of) liver, not elsewhere classified

CLINICAL PEARLS

- NAFLD is a major cause of liver disease. Spectrum ranges from NAFL to NASH, advanced fibrosis, and cirrhosis.
- NAFLD is the most common chronic liver disease in children; there has been a parallel rise in childhood obesity and NAFLD.
- Lifestyle changes with targeted weight loss are the cornerstones of therapy for NAFLD.
- NAFLD is a common cause of asymptomatic mild serum aminotransferase elevation.
NONFATAL DROWNING
Joseph L. Steele, MPAS, APA-C • Natasha J. Pyzocha, DO, FAWM, FAAFP

BASICS

DESCRIPTION
- Respiratory impairment from submersion in liquid (1)
- System(s) affected: cardiovascular, nervous, pulmonary, renal
- Synonym(s): submersion injury; terms such as “near-drowning,” “secondary drowning,” and “wet drowning” should be avoided.

EPIDEMIOLOGY

Incidence
- From 2005 to 2014, an average of 3,536 fatal unintentional drownings in the United States (2)
- Three age-related peaks: toddlers and young children (1 to 5 years), adolescents and young adults (15 to 25 years), and the elderly
- 80% of people who die from drowning are male (2).
- Greater incidence in minorities; African Americans age 5 to 19 years old are affected 5.5 times more frequently than Caucasians (2).

Prevalence
- Most common injury-related cause of death for children 1 to 4 years in the United States (3)
- For every child age <15 years who dies from drowning, five more children are seen in the emergency room for nonfatal submersion injuries.

ALERT
Proper water supervision and safety techniques are critical in avoiding morbidity and mortality from drowning.

ETIOLOGY AND PATHOPHYSIOLOGY
Hypoxemia via aspiration and/or reflex laryngospasm causing cerebral hypoxia and multisystem organ dysfunction
- 10–20% of victims drown without aspiration; likely due to prolonged laryngospasm
- Bathtub and bucket drowning in children <1 year
- Swimming pool drowning in children and young adults
- Motor vehicle accidents (vehicle submerged in water)
- Head trauma while swimming or diving
- Suicide
- Pulmonary: morbidity primarily caused by hypoxia. Aspiration causes dilution of surfactant with decreased gas transfer across alveoli, atelectasis, development of intrapulmonary right-to-left shunting; acute respiratory distress syndrome (ARDS); obstruction due to laryngospasm and bronchospasm
- Cardiac: hypoxic-ischemic injury and arrhythmia (primary or secondary)
- Renal: acute tubular necrosis from hypoxemia, shock, hemoglobinuria, myoglobinuria
- Neurologic: hypoxic-ischemic brain injury with damage especially to the hippocampus, insular cortex, and basal ganglia; cerebral edema
- Coagulation: hemolysis and coagulopathy

**RISK FACTORS**
- Inadequate physical barriers surrounding pools
- Alcohol ingestion; male sex
- Low socioeconomic status
- Use of illicit drugs
- Seizure disorder
- Inability to swim
- Hyperventilation prior to underwater swimming
- Boating mishaps and trauma during water sports, particularly when not wearing a life jacket
- Scuba diving
- Inadequate adult supervision of children; lack of appropriate instruction on how to swim
- Concomitant stroke or myocardial infarction (MI)
- Hypothermia
- Cardiac arrhythmias: familial long QT and polymorphic ventricular tachycardia (VT)

**GENERAL PREVENTION**
- Periodic education regarding proper supervision and drowning prevention for caretakers of young children
- Proper adult supervision of children, particularly around water
- Pool alarms, buddy system
- Knowledge of water safety guidelines
- Mandatory physical barriers surrounding pools; four-sided fencing, self-closing gate at least 48 inches above the ground (2)
- Avoid alcohol or recreational drugs around water.
- Swimming instruction at an early age
- Cardiopulmonary resuscitation (CPR) instruction for pool owners and parents
- Boating safety knowledge
- Personal flotation device and rescue equipment (e.g., preserver, if necessary)

**Pediatric Considerations**
Children should never be left alone near water. Young children can drown in very small amounts of water (bathtubs, buckets, and toilets).

**COMMONLY ASSOCIATED CONDITIONS**
- Trauma
- Seizure disorder
- Alcohol or illicit drug use
- Hypothermia
- Concomitant stroke or MI
- Cardiac arrhythmias: familial long QT and familial polymorphic VT
- Hyperventilation
DIAGNOSIS

HISTORY
The Utstein approach provides a standardized template for evaluating drowning incidents and provides guidance for the history, physical exam, and appropriate management:

- **Core data:** (i) Victim identifier—unique; (ii) Gender; (iii) Race and ethnicity; (iv) Age; (v) Incident date and time of day; (vi) Precipitating event; (vii) Was the face submerged at any time before or at the time of rescue? (viii) Pre-existing illness
- **Scene Information:** (i) Water temperature; (ii) Was the drowning witnessed? (iii) Was bystander CPR performed? (iv) Trained first responder? (v) Vital status at first trained responder assessment—Was the victim responsive? Breathing normally? Pulse palpable? (vi) Initial cardiac rhythm. Supplementary data; (vii) Vital signs at first EMS assessment; (viii) Pulmonary status at first EMS assessment; (ix) Type of water/liquid; (x) Body of water
- **Time points and intervals from EMS:** (i) Time face was first seen to be underwater; (ii) Time victim was removed from water; (iii) Duration underwater (submersion duration); (iv) Time of first trained responder treatment; (v) Time trained responder started CPR on scene; (vi) Time return of spontaneous circulation achieved; (vii) Time first conscious/awake; (viii) Interval from face first submerged to first treatment/CPR

PHYSICAL EXAM
- Airway status and degree of respiratory distress
- Pulse: absent, weak, or normal
- Vital signs, including pulse oximetry
- Glasgow Coma Scale (GCS)
- Pulmonary: rales, wheezing
- Cardiac: rate, rhythm
- Neurologic examination

DIFFERENTIAL DIAGNOSIS
Syncopal event, head trauma, arrhythmia, seizure, MI, stroke, alcohol or other substance overdose, nonaccidental trauma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Unnecessary if initial GCS and pulse oximetry are normal (and remain so for 6 to 8 hours)

- CBC with differential
- Arterial blood gas (ABG): hypoxia, hypercarbia, acidosis
- Electrolytes: hypokalemia, hyponatremia, hypernatremia
- Blood glucose: Increased levels may impair neurologic recovery after ischemic brain injury.
- BUN, creatinine: acute tubular necrosis
- ECG, cardiac monitoring, and serial troponin: MI
- Creatine kinase (CK) and urine myoglobin: rhabdomyolysis
- Coagulation studies: coagulopathy
- Toxicology screen
- Blood alcohol level
- Chest x-ray (CXR) unnecessary if all of the following:
  - Normal initial GCS and pulse oximetry
Follow-Up Tests & Special Considerations
- Observe patients with an initial GCS of 15 and pulse oximetry >95% for 6 to 8 hours in the emergency department (ED).
- CXR findings may be minimal or absent early on.

Diagnostic Procedures/Other
- Continuous cardiac monitoring and pulse oximetry
- Continuous core temperature monitoring if hypothermic
- 12-lead ECG
- Central venous pressure (CVP) monitoring for critically ill with hypotension refractory to IV fluids
- Electroencephalogram (EEG) if seizure suspected

TREATMENT
Early resuscitation and reversal of hypoxemia/acidosis are key.

GENERAL MEASURES
- Prehospital
  - Never approach a struggling victim alone.
  - Initiate basic life support (BLS) and advanced cardiovascular life support (ACLS) evaluation (4).
  - Rescue breathing may be helpful if the victim is in the water and cannot be removed; chest compressions not as effective while in the water and may harm the rescuer and the victim (4)[C].
  - Remove the victim from the water and begin effective resuscitation as quickly as possible (5).
  - Immediate CPR (airway, breathing, and circulation [ABC] sequence) (4)[A]
  - Start CPR if pulse is not definitely felt within 10 seconds, even in the hypothermic victim whose heart rate may be severely bradycardic (4)[C].
  - Routine cervical collar use and spinal precautions are not needed unless trauma suspected (5)[C].
  - Supplemental oxygen and early intubation with mechanical ventilation, if needed (1)[A]
  - Rapid crystalloid infusion if hypotension not corrected by oxygenation (1)[A]
  - If patient is breathing on his or her own and does not need spinal precautions, consider placing in the right lateral decubitus position to prevent aspiration of vomit or gastric contents (1).
- ED
  - Oxygen, as needed, to maintain saturation between 92% and 96% (1)
  - Continuous positive airway pressure (CPAP), bilevel positive airway pressure (BiPAP), or intubation if supplemental oxygen alone is inadequate.
– If intubation is indicated, employ lung-protective ventilator settings (lower end-inspiratory airway pressures, lower tidal volumes of 6 mL/kg, higher positive end-expiratory pressures of 6 to 12 cm H₂O) to avoid barotrauma (4)[A].

– Indications for intubation
  o Neurologic deterioration
  o Inability to protect the airway
  o Inability to maintain oxygen saturation >90% or PaO₂ >60 mm Hg on high-flow supplemental oxygen
  o PaCO₂ >50 mm Hg
– Remove wet clothing and initiate rewarming.
– Obtain core temperature to rule out hypothermia.
– If hypothermic, rewarmed with minimally invasive core techniques such as warm IV fluids, warm/humidified oxygen, and external blanketing.
– Active core rewarming only for refractory cases

MEDICATION

First Line
- High-flow oxygen, as needed (1)[A]
- For bronchospasm: aerosolized bronchodilator (3)[C]: albuterol (Proventil, Ventolin), 3 mL of 0.083% solution or 0.5 mL of 0.5% solution diluted in 3 mL of saline
- Vasopressors, as needed, for hypotension refractory to IV fluid resuscitation
- Prophylactic antibiotics are not recommended (1)[B].

Second Line
For pneumonia: antibiotics based on sputum or endotracheal lavage culture (1)[A]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit all symptomatic patients or patients with abnormal vital signs, mental status, oxygenation, CXR, or laboratory analysis.
- Monitor vital signs and reassess neurologic status; continuous cardiac and pulse oximetry monitoring
- After initial resuscitation, induce hypothermia with core temp maintained between 32°C and 34°C for 24 hours; may be neuroprotective for patients that remain comatose or have neurologic deterioration (1)
- Patients can be discharged from the ED after 6 to 8 hours of observation if the following criteria are met:
  – GCS = 15
  – Normal CXR, if indicated
  – Lack of clinical evidence of respiratory difficulty
  – Normal lung exam
  – Normal vital signs
  – Oxygen saturation ≥95% on room air (5)

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Appropriate follow-up with primary care provider, orthopedic, neurologic, cardiac, pulmonary, and additional specialists as indicated

Patient Monitoring
- ABG monitoring, as indicated
- A pulmonary artery catheter may be needed for hemodynamic monitoring in unstable patients (3)[C].
- Intracranial pressure monitoring in selected patients (3)[C]
- Serum electrolyte determinations

DIET
NPO until mental status normalizes

PATIENT EDUCATION
Reemphasize preventive measures on discharge from hospital and educate parents regarding supervision and preventive practices.

PROGNOSIS
- 75% of drowning victims survive; 6% will have residual neurologic deficits (1).
- Patients with an initial GCS ≥13 and an oxygen saturation ≥95% have a low risk of complications and an excellent chance for a full recovery (1).
- Patients who are comatose or receiving CPR at the time of presentation and those who have dilated and fixed pupils and no spontaneous respiratory activity have a poor prognosis.
- Neurogenic pulmonary edema may occur within 48 hours of initial presentation.

COMPLICATIONS
- Early
  - Bronchospasm, vomiting, aspiration
  - Hypoglycemia, hypothermia, seizures
  - Hypovolemia, electrolyte abnormalities
  - Arrhythmia from hypoxia or hypothermia (rarely from electrolyte imbalance)
  - Hypotension
- Late
  - ARDS, pneumonia, lung abscess, empyema
  - Anoxic encephalopathy, barotrauma, seizure
  - Renal failure, coagulopathy, sepsis

ADDITIONAL READING

CODES

ICD10

- T75.1XXA Unsp effects of drowning and nonfatal submersion, init
- T75.1XXD Unsp effects of drowning and nonfatal submersion, subs
- T75.1XXX Unsp effects of drowning and nonfatal submersion, sequel

CLINICAL PEARLS

- The most important treatment for near-drowning victims is prompt reversal of any hypoxia.
- Water safety education (combining physical and behavioral techniques) has the greatest impact on drowning prevention.
- Encourage pool owners and parents with young children to become CPR certified.
- Patients remain at risk for ARDS for hours after submersion. All resuscitated patients require careful monitoring.
- Use lung-protective ventilator settings for intubated patients to prevent barotrauma.
- Patients with an initial GCS ≥13 and an oxygen saturation ≥95% have a low risk of complications and an excellent chance for a full recovery.
OBESITY
Kimberly Bombaci, MD

BASICS

DESCRIPTION
- Excess adipose tissue, typically quantified in adults by body mass index (BMI) ([kg]/[m^2]), ≥30 kg/m^2.
- Obesity categorized into three classes:
  - Class 1 obesity is BMI 30 to 34.9 kg/m^2.
  - Class 2 obesity is BMI 35 to 39.9 kg/m^2.
  - Class 3 obesity (also called severe obesity) is BMI >40 kg/m^2.
- Obesity is associated with negative health outcomes. Abdominal obesity increases the risk of morbidity and mortality.
- System(s) affected: endocrine/metabolic, cardiac, respiratory, gastrointestinal (GI), musculoskeletal, dermatologic, mental health
- Synonym(s): overweight; adiposity

Geriatric Considerations
Underweight BMI (≤18) is also associated with an increased risk of mortality.

EPIDEMIOLOGY
- Predominant age: Incidence rises in the early 20s.
- Predominant sex: female > male

Prevalence
- 35% of U.S. adults are obese (1,2).
- 40% of men and 25% of women are overweight.

Pediatric Considerations
- The USPSTF recommends that clinicians screen for obesity in children and adolescents ≥6 years and refer them to comprehensive, intensive behavioral interventions to promote improvements in weight status (grade B recommendation).
- Pediatric obesity is defined as a BMI ≥95th percentile, by age- and sex-specific WHO or CDC growth curves.
- Obesity during adolescence and young adulthood is strongly associated with obesity in adulthood.

ETIOLOGY AND PATHOPHYSIOLOGY
- Obesity is caused by an imbalance between food intake, absorption, and energy expenditure.
- Underlying organic causes include psychiatric disturbances, hypothyroidism, hypothalamic disorders, insulinoma, and Cushing syndrome. It is likely that an individual’s gut microbiome may cause obesity and/or make it difficult to lose weight.
- Medications that contribute to obesity include corticosteroids, neuroleptics (particularly atypical antipsychotics), and antidepressants.
Genetics
- Genetic syndromes such as Prader-Willi and Bardet-Biedl are found in a minority of people with obesity.
- Multiple genes are implicated in obesity.

RISK FACTORS
- Parental obesity
- Sedentary lifestyle
- Consumption of calorie-dense food
- Low socioeconomic status
- Stress and mental illness
- Medications

GENERAL PREVENTION
- Encourage at least 1 hour of daily exercise, limited television viewing, and moderation in portion size.
- Avoid calorie-dense and nutrient-poor foods such as sugar-sweetened beverages and processed foods.

DIAGNOSIS

HISTORY
- Diet and exercise habits
- Prior attempts at weight loss
- Reported readiness to change lifestyle
- Social support and resources
- Comorbidities: diabetes mellitus type 2, hypertension (HTN), hyperlipidemia, sleep apnea
- Psychiatric history
- Symptoms suggesting hypothyroidism, Cushing syndrome, and genetic syndromes

PHYSICAL EXAM
- Elevated BMI:
  - Overweight: BMI = 25 to 29.9 kg/m²
  - Obese: BMI 30 to 39.9 kg/m²
  - Morbid obesity: BMI ≥40 kg/m²
- Abdominal circumference:
  - Measure at the level of the umbilicus. Elevated:
    - Male: >40 inches (102 cm)
    - Female: >35 inches (88 cm)

DIAGNOSTIC TESTS & INTERPRETATION
- Screen for underlying physiologic causes as well as associated comorbid conditions.
- Glucose, total insulin, hemoglobin A1C, lipids
- Thyroid function tests
- LFTs (fatty liver)
TREATMENT

GENERAL MEASURES
- Assess:
  - Motivation to lose weight
  - Patient-specific goals of therapy
  - Need for intensive counseling to enhance adherence with diet, exercise, and behavior modification recommendations
- Goal is to achieve and sustain loss of at least 10% of body weight.
- Track nutritional intake and physical activity habits.
- Use of commercial weight loss programs (e.g., Weight Watchers) can be more effective than “standard of care” counseling (3)[B].
- Behavior therapy and cognitive behavioral methods result in modest weight loss and are most effective when combined with dietary and exercise treatments.
- Diet
  - Long-term studies suggest net calorie reduction (500 to 1,000 kcal/day) and ease of use are more important than the composition of the particular diet for long-term results:
    - A reduction of 500 kcal/day can result in ~1 lb (0.45 kg) weight loss per week.
    - Portion-control is essential.
  - Very low calorie diet (400 to 800 kcal/day)
    - Can result in more rapid weight loss than higher calorie diets but is less effective in the long term
    - Complications include dehydration, orthostatic hypotension, fatigue, muscle cramps, constipation, headache, and cold intolerance.
    - Relapse common if diet discontinued
    - Contraindications: recent myocardial infarction or cerebrovascular accident, renal disease, cancer, pregnancy, insulin-dependent diabetes mellitus, and some psychiatric disturbances

MEDICATION
- Include diet, exercise, and behavior therapy for all patients without comorbid conditions who are considering pharmacologic treatment.
- NIH guidelines suggest at least 6 months nonpharmacologic treatment.
- Consider medication for unsatisfactory weight loss in those with:
  - BMI ≥30
  - BMI ≥27 combined with associated risk factors (e.g., coronary artery disease, diabetes, sleep apnea, HTN, hyperlipidemia)
- Relapse is common after medications are discontinued.
- Treat comorbidities (such as diabetes and hyperlipidemia).

First Line
- When compared to placebo, medications have been associated with at least 5% weight loss at 52 weeks (4)[A]. Orlistat (Xenical) is a lipase inhibitor that decreases the absorption of dietary fat. Dose: 120 mg PO TID with meals containing fat; omit dose if meal is skipped or does not contain fat. Patients must avoid taking fat-soluble vitamin supplements within 2 hours of taking orlistat. The FDA has approved orlistat (Alli) 60 mg PO TID to be sold over the counter.
as a weight loss aid; adverse effects mainly GI (cramps, flatus, fecal incontinence)

- Orlistat: chronic malabsorption syndromes, cholestasis, pregnancy

**Second Line**

- Appetite suppressants recommended for short-term treatment (≤6 months) \(5\)[A]
- Only beneficial in patients who exercise and eat reduced calorie diet
  - Naltrexone/bupropion (Contrave): 8 mg naltrexone/90 mg bupropion per tablet; slow titration up to 2 tablets PO BID by week 4; contraindicated if uncontrolled HTN, seizure disorder, chronic opioid use, pregnancy
  - Liraglutide (Saxenda): 1.203 mg SC once daily; GLP-1 agonist recently approved for obesity; discontinue if weight loss is <4% after 16 weeks.
  - Topiramate: Initiate with 25 mg BID and increase by 50 mg/week up to 100 mg PO BID; not FDA-approved for the treatment of obesity; tolerance is a concern (paresthesias, somnolence, difficulty concentrating).

- Schedule IV drugs:
  - Lorcaserin (Belviq) 10 mg PO BID (D/C if weight loss is <5% after 12 weeks); works as serotonin agonist; avoid in those with CrCl <30 mL/min; contraindicated in pregnancy; avoid use with other serotonergic drugs.
  - Phentermine: 15, 30, 37.5 mg PO every morning; discontinue if tolerance or no response after 4 weeks; contraindicated if history of CV disease, hyperthyroidism, history of substance abuse, pregnancy.
  - Phentermine/topiramate (Qsymia, 3.75 to 23.00 mg, 7.5 to 46.0 mg, 11.25 to 69.00 mg, 15 to 92 mg); initiate 3.75 to 23.00 mg PO once daily; requires enrollment into Risk Evaluation and Mitigation Strategy (REMS); women of childbearing age require negative pregnancy test prior to initiation and monthly thereafter.
  - Diethylpropion: 25 mg PO before meals TID; discontinue if no response after 4 weeks; contraindicated if severe HTN, hyperthyroidism, history of substance abuse.

**SURGERY/OTHER PROCEDURES**

- Bariatric (weight loss) surgery for obesity is considered when other treatments have failed.
- Surgical treatment is the most effective long-term weight-loss treatment available for morbidly obese patients, but there is insufficient evidence on long-term outcomes \(6\)[A].
- Requires complex presurgical evaluation, surgery, and follow-up in a skilled treatment center.
- Surgical procedures include biliopancreatic diversion, Roux-en-Y gastric bypass, sleeve gastrectomy, adjustable gastric banding, vagal blocking therapy (Maestro Rechargeable System), and gastric aspiration (AspireAssist).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Physical activity is an integral part of any weight loss program, yet physical activity alone rarely results in significant weight loss.
- Combination of weight training and aerobic activity is preferred over aerobic activity alone.

**Patient Monitoring**
Long-term routine follow-up may prevent relapse after weight loss or further weight gain.

**PATIENT EDUCATION**
- Healthy diet and physical activity patterns
- Focus on behaviors (not numbers).
- Recommended Web site: https://www.nal.usda.gov/fnic/foodcomp/search for the FDA nutritional content in common foods

**PROGNOSIS**
- Lowest mortality associated with a BMI of 22
- Long-term maintenance of weight loss is difficult.
- Patient motivation is associated with successful weight loss (7).

**COMPLICATIONS**
- Cardiovascular disease
- Stroke (in men)
- Thromboembolism
- Heart failure
- HTN
- Hypoventilation and sleep apnea syndromes
- Higher death rates from cancer: colon, breast, prostate, endometrial, gallbladder, liver, kidney
- Diabetes mellitus
- Skin changes
- Hyperlipidemia
- Gallbladder disease
- Osteoarthritis
- Gout
- Poor self-esteem
- Discrimination
- Increased sick leave

**REFERENCES**

CODES

ICD10
- E66.9 Obesity, unspecified
- E66.3 Overweight
- R63.5 Abnormal weight gain

CLINICAL PEARLS

- A majority of American adults are overweight or obese.
- Modification in dietary and physical activity patterns remains the cornerstone of therapy for obesity. Consider bariatric surgery in patients with a BMI >40 who have failed more conservative treatment, particularly if there are associated risk factors.
- Medication may be indicated when nonpharmacologic treatment for 6 months has been ineffective and the patient has a BMI >30 or a BMI >27 with associated risk factors.
OBSESSIVE-COMPULSIVE DISORDER (OCD)
Amar Kapur, DO

**BASICS**

**DESCRIPTION**
- An anxiety disorder characterized by pathologic obsessions (recurrent intrusive thoughts, ideas, or images) and compulsions (repetitive, ritualistic behaviors or mental acts) causing significant distress
- Not to be confused with obsessive-compulsive personality disorder

**EPIDEMIOLOGY**

**Incidence**
- Predominant age: mean age of onset 22 to 36 years
  - Male = female (males present at younger age)
  - Child/adolescent onset in 33% of cases 1/3 of cases present by age 15 years
  - 85% of cases present at <35 years of age
  - Diagnosis rarely made at >50 years of age
- Predominant gender: female > males but males more commonly affected in childhood

**Pediatric Considerations**
Insidious onset; consider brain insult in acute presentation of childhood obsessive-compulsive disorder (OCD).

**Geriatric Considerations**
Consider neurologic disorders in new-onset OCD.

**Prevalence**
- 2.3% lifetime in adults
- 1–2.3% prevalence in children/adolescents (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Exact pathophysiology/etiology unknown
- Dysregulation of serotonergic pathways
- Dysregulation of corticostriatal-thalamic-cortico (CSTC) path
- Genetic and environmental factors
- Pediatric autoimmune disorder associated with streptococcal infections (controversial)

**Genetics**
- Greater concordance in monozygotic twins
- Positive family history: prevalence rates of 7–15% in first-degree relatives of children/adolescents with OCD

**RISK FACTORS**
- Exact cause of OCD is not fully elucidated.
- Combination of biologic and environmental factors likely involved the following:
  - Link between low serotonin levels and development of OCD
– Link between brain insult and development of OCD (i.e., encephalitis, pediatric streptococcal infection, or head injury)

**GENERAL PREVENTION**

- OCD cannot be prevented.
- Early diagnosis and treatment can decrease patient’s distress and impairment.

**COMMONLY ASSOCIATED CONDITIONS**

- Major depressive disorder
- Panic disorder
- Phobia/social phobia
- Tourette syndrome/tic syndromes
- Substance abuse
- Eating disorder/body dysmorphic disorder

**DIAGNOSIS**

**HISTORY**

- Patient presents with either obsessions or compulsions that cause marked distress, are time consuming (>1 hr/day) and cause significant occupational/social impairment.
- Four criteria support diagnosis of obsessions:
  - Patients are aware that they are thinking the obsessive thoughts; thoughts are not imposed from outside (as in thought insertion).
  - Thoughts are not just excessive worrying about real-life problems.
  - Recurrent thoughts are persistent, intrusive, and inappropriate, causing significant anxiety and distress.
  - Attempts to suppress intrusive thoughts are made with some other thought/activity.
- Two criteria support a diagnosis of compulsions:
  - The response to an obsession is to perform repetitive behaviors (e.g., hand washing) or mental acts (e.g., counting silently) rigidly.
  - Although done to reduce stress, the responses are either not realistically connected with the obsession or they are excessive.
- In children, check for precedent streptococcal infection.

**PHYSICAL EXAM**

- Dermatologic problems caused by excessive hand washing may be observed.
- Hair loss caused by compulsive pulling/twisting of the hair (trichotillomania) may be observed.

**DIFFERENTIAL DIAGNOSIS**

- Obsessive-compulsive personality disorder
  - In personality disorder, traits are ego-syntonic and include perfectionism and preoccupation with detail, trivia, or procedure and regulation. Patients tend to be rigid, moralistic, and stingy. These traits are often rewarded in the patient’s job as desirable.
- Impulse-control disorders: compulsive gambling, sex, or substance abuse: The compulsive behavior is not in response to obsessive thoughts, and the patient derives pleasure from the activity.
Major depressive disorder
Eating disorder
Tics (in tic disorder) and stereotyped movements
Schizophrenia: Patient perceives thought to be true and coming from an external source; DSM-5 revisions also clarify that while OCD patients may lack insight, they lack the other features associated with schizophrenia such as hallucinations.
Generalized anxiety disorder, phobic disorders, separation anxiety: similar response on heightened anxiety, but presence of obsessions and rituals signifies OCD diagnosis
Hoarding disorders: obsessions about the completeness of the “collection” and compulsive hoarding

DIAGNOSTIC TESTS & INTERPRETATION
According to DSM-5, diagnostic criteria for OCD are the following (2)[C]:

- Presence of obsessions, compulsions, or both
- Obsessions are defined by:
  - Recurrent or persistent thoughts, urges, or images that are experienced as intrusive and unwanted and that cause marked anxiety or distress
  - The individual attempts to ignore or suppress such thoughts, urges, or images or to neutralize them with some other thought or actions (i.e., by performing compulsion).
- Compulsions are defined by the following:
  - Repetitive behavior (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly
  - The behavior or mental acts are aimed at preventing or reducing anxiety or distress or preventing some dreaded event or situation. However, these behavior or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent or are clearly excessive.
- The obsessions or compulsions are time-consuming (e.g., take >1 hr/day) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
- The obsessive-compulsive symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, or other medical condition).
- The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder; preoccupation with appearance, as in body dysmorphic disorder or skin picking).
- Specify if:
  - With good or fair insight: The individual recognizes the OCD beliefs are definitely or probably not true or that they may or may not be true.
  - With poor insight: The individual thinks that OCD beliefs are probably true.
  - With absent insight/delusional beliefs: The individual is completely convinced that OCD beliefs are true.
- Specify if:
  - Tic related: The individual has a current or past history of tic disorder.

Diagnostic Procedures/Other
Yale-Brown Obsessive-Compulsive Scale (YBOCS) used to assess severity of OCD and can be used to monitor progress (3)
Test Interpretation

- Compulsions are designed to relieve the anxiety of obsessions; they are not inherently enjoyable (ego-dystonic) and do not result in completion of a task.
- Common obsessive themes
  - Harm (i.e., being responsible for an accident)
  - Doubt (i.e., whether doors/windows are locked or the iron is turned off)
  - Blasphemous thoughts (i.e., in a devoutly religious person)
  - Contamination, dirt, or disease
  - Symmetry/orderliness
- Common rituals or compulsions
  - Hand washing, cleaning
  - Checking
  - Counting
  - Hoarding
  - Ordering, arranging
  - Repeating
- Neither obsessions nor compulsions are related to another mental disorder (i.e., thoughts of food and presence of eating disorder).
- 80–90% of patients with OCD have obsessions and compulsions.
- 10–19% of patients with OCD are pure obsessional.

TREATMENT

GENERAL MEASURES

- Cognitive-behavioral therapy (CBT) composed of exposure with response prevention and cognitive therapy is recommended as first-line treatment (1)[A].
- Five phases of treatment for CBT:
  - Family and individual psychoeducation
  - Cognitive training
  - Mapping OCD
  - Graded exposure and response training
  - Relapse prevention and generalization training
- Combined medications and CBT is most effective (1,2)[A].
- Brain modulation available for severe OCD includes electroconvulsive therapy and transcranial magnetic stimulation in small groups of patients.

MEDICATION

First Line

- Adequate trial at least 10 to 12 weeks
- Doses may exceed typical doses for depression.
- Optimal duration for pediatrics unknown but recommended minimum of maintenance treatment: 6 months
- Varying degrees of efficacy between agents (1)
- SSRIs recommended first-line agents (1,4,5)[A]
  - Fluoxetine (Prozac)
Adults: 20 mg/day; increase by 10 to 20 mg every 4 to 6 weeks until response; range: 20 to 80 mg/day
Children (7 to 17 years of age): 10 mg/day; increase 4 to 6 weeks until response; range: 20 to 60 mg/day

- **Sertraline (Zoloft)**
  - Adults: 50 mg/day; increase by 50 mg every 4 to 7 days until response; range: 50 to 200 mg/day; may divide if >100 mg/day
  - Children (6 to 17 years of age): 25 mg/day; increase by 25 mg every 7 days until response; range: 50 to 200 mg/day

- **Paroxetine (Paxil)**
  - Adults: 20 mg/day; increase by 10 mg every 4 to 7 days until response; range: 40 to 60 mg/day
  - Children: Safety and effectiveness in patients <18 years have not been established.

- **Citalopram (Celexa)**
  - Not approved by the FDA for use in OCD but used frequently due to good tolerability
  - Black box warning of no more than 40 mg/day due to arrhythmia risk

**Absolute SSRI contraindications**
- Hypersensitivity to SSRIs
- Concomitant use within 14 days of monoamine oxidase inhibitor (MAOI)

**Relative SSRI contraindications**
- Severe liver impairment
- Seizure disorders (lower seizure threshold)

**Precautions**
- Watch for suicidal behavior/worsening depression during first few months of therapy/after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
- Long half-life of fluoxetine (>7 days) may be troublesome if patient has an adverse reaction.
- May cause drowsiness and dizziness when therapy was initiated; warn patients about driving and heavy equipment hazards.

**Pregnancy Considerations**
All SSRIs are pregnancy Category C, except paroxetine, which is Category D.

**Second Line**
- Try switching to another SSRI.
- 40–60% of patients will remain refractory to SSRI.

- **Tricyclic acid (TCA), clomipramine (Anafranil)**
  - Adults: 25 mg/day; increase gradually over 2 weeks to 100 mg/day and then to 250 mg/day (max dose) over next several weeks, as tolerated.
  - Children (10 to 17 years of age): 25 mg/day; titrate as needed and tolerated up to 3 mg/kg/day or 200 mg/day (whichever is less).

- **Absolute clomipramine contraindications**
  - Within 6 months of a myocardial infarction (MI)
  - Hypersensitivity to clomipramine or other TCA
  - Concomitant use within 14 days of a MAOI
  - 3rd-degree atrioventricular (AV) block

- **Relative clomipramine contraindications**
Narrow-angle glaucoma (increased intraocular pressure)
- Prostatic hypertrophy (urinary retention)
- 1st- or 2nd-degree AV block, bundle-branch block, and congestive heart failure (proarrhythmic effect)
- Pregnancy Category C

**Precautions**
- Dangerous in overdose
- Pretreatment ECG for patients >40 years of age; potential arrhythmia (4)
- Watch for suicidal behavior/worsening depression during first few months of therapy or after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
- May cause drowsiness and dizziness when therapy is initiated; warn patients about driving and heavy equipment hazards (4).
- Side effect profile worse than SSRIs as a whole (4)

**ISSUES FOR REFERRAL**
- Psychiatric referral for CBT (in vivo exposure and prevention of compulsions)
- Psychiatric evaluation if obsessions and compulsions significantly interfere with patient’s functioning in social, occupational, or educational situations

**ADDITIONAL THERAPIES**

Dopamine receptor antagonists (antipsychotic agents) alone are not effective in treatment of OCD. They can be used as augmentation to SSRI therapy for treatment-resistant OCD; they also can worsen OCD symptoms (4)[C]. Some evidence shows that addition of quetiapine or risperidone to antidepressants will increase efficacy; data with olanzapine too limited to draw conclusions (4)[A]

- Risperidone (Risperdal): initial dose: 0.5 mg/day; target dose: 0.5 to 2.0 mg/day
- Quetiapine (Seroquel): initial dose: 25 mg/day; target dose: 600 mg/day

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Y-BCOS survey to track progress (3)

**Patient Monitoring**

Monitor for decrease in obsessions and time spent performing compulsions.

**DIET**

No dietary modifications/restrictions recommended

**PATIENT EDUCATION**

- Importance of medication adherence
- Importance of psychotherapy (CBT)
- International OCD Foundation: [https://iocdf.org/](https://iocdf.org/)
- Obsessive Compulsive Anonymous: [http://obsessivecompulsiveanonymous.org](http://obsessivecompulsiveanonymous.org)

**PROGNOSIS**
Chronic waxing and waning course in most patients:
- 24–33% fluctuating course
- 11–14% phasic periods of remission
- 54–61% chronic progressive course

Early onset a poor predictor
Few studies address how long to continue therapy; poor results for those who do with high relapse rate (53% on placebo compared to 23% on stable escitalopram) (4,6)
Patients who are classified as “responders” will continue to have symptoms, often significantly impacting their lives.

COMPLICATIONS
- Depression in 1/3 patients with OCD
- Avoidant behavior (phobic avoidance)
  - Children may drop out of education.
  - Adults may become homebound.
- Anxiety and panic-like episodes associated with obsessions

REFERENCES

CODES
ICD10
- F42 Obsessive-compulsive disorder
- F63.9 Impulse disorder, unspecified
- F63.3 Trichotillomania

CLINICAL PEARLS
- CBT is the initial treatment of choice for mild OCD.
- CBT plus an SSRI or an SSRI alone is the treatment choice for more severe OCD.
- The majority of patients with OCD respond to first SSRI treatment.
Improvement in symptoms, however, is often incomplete, ranging from 25% to 60%.
OCULAR CHEMICAL BURNS
Jonathan Tsui, MD • Tarika Thareja, MD

BASICS

DESCRIPTION
- Chemical exposure to the eye can result in rapid, devastating, and permanent damage and is one of the true emergencies in ophthalmology.
- Types of chemical exposure:
  - Alkali burns: more severe. Alkaline compounds are lipophilic, penetrating rapidly into eye tissue; saponification of cell membranes leads to necrosis and may produce injury to lids, conjunctiva, cornea, sclera, iris, and lens (cataracts).
  - Acid burns: Acid usually does not damage internal structures because its associated anion causes protein denaturation, creating a barrier to further acid penetration (hydrofluoric acid is an exception to this rule; see below). Injury is often limited to lids, conjunctiva, and cornea.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): chemical ocular injuries

EPIDEMIOLOGY
- Predominant age: can occur at any age, peak from 20 to 40 years of age
- Predominant sex: male > female

Incidence
- Estimated 300/100,000 per year
- Chemical burns account for 11.5–22.1% of all ocular injuries.
- Alkali burns are twice as common as acid burns.

ETIOLOGY AND PATHOPHYSIOLOGY
- Alkaline compounds
  - Lipophilic compounds that penetrate into deep structures on disassociation into cations and hydroxide
  - Hydroxide causes saponification of fatty acids in cell membranes, leading to cell death.
  - Cation causes hydration of glycosaminoglycans, leading to corneal opacification and hydration of collagen, resulting in rapid shortening and thickening of collagen fibrils that leads to an acute elevation in intraocular pressure (IOP) secondary to shrinking and contraction of the cornea and sclera.
  - Long-term elevation in IOP may occur from accumulation of inflammatory debris within the trabecular meshwork.
  - Penetration into deep structures may also affect perfusing vessels, leading to ischemia of affected area.
- Acidic compounds
  - Anion leads to protein denaturing and protective barrier formation by coagulation necrosis forming an eschar. This more superficial mechanism of injury tends to have prominent scarring that may lead to vision loss:
    - Hydrofluoric acid is an exception. In its nonionized form, it behaves like an alkaline
substance, capable of penetrating the corneal stroma and leading to extensive anterior segment lesions. When ionized, it may combine with intracellular calcium and magnesium to form insoluble complexes, leading to potassium ion movements and cell death. Once systemically absorbed, severe hypocalcemia can occur.

### Sources of Alkaline and Acidic Compounds

<table>
<thead>
<tr>
<th>Alkaline Compounds</th>

</tbody>
</table>

### RISK FACTORS
- Construction work (plaster, cement, whitewash)
- Use of cleaning agents (drain cleaners, ammonia)
- Automobile battery explosions (sulfuric acid)
- Industrial work, including work in industrial chemical laboratories
- Alcoholism
- Any risk factor for assault (~10% of injuries due to deliberate assault)

### GENERAL PREVENTION
Safety glasses/goggles to safeguard eyes

### COMMONLY ASSOCIATED CONDITIONS
Facial (including eyelids) cutaneous chemical or thermal burns

### DIAGNOSIS

#### HISTORY
- Pain, photophobia, blurred vision, and foreign body sensation
- Chemical involved, duration of exposure, velocity of impact, and involved area
- In alkali burns, can have initial pain that later diminishes.
- Mild burns: pain and blurred vision
- Moderate to severe burns: severe pain and markedly reduced vision

#### PHYSICAL EXAM
- Alkaline compounds may present with corneal opacification secondary to glycosaminoglycan hydration; however, severe acid burns may also present with this finding.
- Acidic compound may present with a ground-glass appearance secondary to superficial scar formation.
- Mild burns
- Blurry vision
- Eyelid skin erythema and edema
- Corneal epithelial defects or superficial punctate keratitis
- Conjunctival chemosis, hyperemia, and hemorrhages without perilimbal ischemia
- Mild anterior chamber reaction
- Moderate to severe burns
  - Decreased visual acuity
  - 2nd- and 3rd-degree burns of eyelid skin
  - Corneal edema and opacification
  - Corneal epithelial defects
  - Marked conjunctival chemosis and perilimbal blanching
  - Moderate anterior chamber reaction
  - Increased IOP
  - Local necrotic retinopathy

**DIFFERENTIAL DIAGNOSIS**
- Thermal burns
- Ocular cicatricial pemphigoid
- Infectious keratitis
- Ultraviolet radiation keratitis
- Foreign body
- Acute angle glaucoma
- Conjunctivitis

**DIAGNOSTIC TESTS & INTERPRETATION**
Not necessary unless suspicion of intraocular or orbital foreign body is present. In this case, CT scan should be used and magnetic resonance imaging is contraindicated.

**Diagnostic Procedures/Other**
- Measure pH of tear film with litmus paper or electronic probe:
  - Irrigating fluid with nonneutral pH (e.g., normal saline has pH of 4.5) may alter results.
- Careful slit-lamp exam, fundus ophthalmoscopy, tonometry, and measurement of visual acuity
- Full extent of damage from alkali burns may not be apparent until 48 to 72 hours after exposure.

**Test Interpretation**
- Corneal epithelial defects or superficial punctate keratitis, edema, opacification
- Conjunctival chemosis, hyperemia, and hemorrhages
- Perilimbal ischemia
- Anterior chamber reaction
- Increased IOP

**TREATMENT**
Copious irrigation and removal of corneal or conjunctival foreign bodies are always the initial treatment and paramount to minimizing long-term sequelae (1,2,3,4)[A]:
- Passively open patient’s eyelid and have patient look in all directions while irrigating.
- Be sure to remove all reservoirs of chemical from the eyes via lid eversion.
- Continue irrigation until the tear film and superior/inferior cul-de-sac is of neutral pH (7.2 ± 0.1) and stable, testing every 30 minutes (1,3)[A]:
  - Severe burns should be irrigated for at least 15 to 30 minutes to as much as 2 to 4 hours; this irrigation should not be interrupted during transportation to hospital (1,3)[B].
  - Irrigation via Morgan lens (polymethylmethacrylate scleral lens) is a good way to achieve continuous irrigation over a prolonged period of time.
- Initial pH testing should be done on both eyes even if the patient claims to only have unilateral ocular pain/irritation so that a contralateral injury is not neglected.
- Use whatever nontoxic fluid is available for irrigation on scene. In hospital, sterile water, normal saline, normal saline with bicarbonate, balanced salt solution (BSS), lactated Ringer solution, Diphoterine or Cederroth eye wash may be used (5)[B].
  - Diphoterine or Cederroth eye wash has shown better patient comfort and healing but should not prevent prompt irrigation if not readily available (2)[B].
- A topical anesthetic can be used to provide patient comfort (e.g., proparacaine, tetracaine).
- Sweep the conjunctival fornices every 12 to 24 hours to prevent adhesions (3)[C].

**MEDICATION**

**First Line**

- Further treatment aims to decrease inflammation and collagen degradation and aid in collagen synthesis and recovery of corneal epithelium. Selection depends on severity and associated conditions.
  - Topical prophylactic antibiotics: any broad-spectrum agent (e.g., bacitracin–polymyxin B ointment q2–4h, ciprofloxacin drops q2–4h)
    - Some experts suggest adding systemic tetracycline 250 mg PO q6h and especially derivatives such as doxycycline 100 mg PO BID, which may be beneficial to encourage healing and prevent corneal ulceration (1),(2)[C].
  - Tear substitutes: carboxymethylcellulose (Refresh Plus) drops q4h
    - Promotes re-epithelialization, reduces recurrent erosion risk, and increases visual rehab (1,2)[A]
  - Cycloplegics for photophobia and/or uveitis: cyclopentolate 1% TID or scopolamine 1/4% BID (3,4)[C]
  - Corticosteroids for intraocular inflammation: prednisolone 1% or equivalent q2h for 7 to 10 days; if severe, prednisone 20 to 60 mg PO daily for 5 to 7 days. Taper rapidly if epithelium is intact, by day 10 to 14 (1,3)[C]:
    - Using vitamin C in conjunction with steroids reduces incidence of corneal thinning, ulceration, and perforation (1,2,3)[A].
    - Vitamin C (ascorbic acid) 500 mg PO QID and topical 10% q2h ascorbate solution in artificial tears
  - Acetylcysteine (Mucomyst) 10–20% topically q4h may promote wound healing (1,3)[B].
  - Ocular antihypertensives for IOP >30 to reduce risk of optic nerve damage: latanoprost 0.005% qhs, timolol 0.5% BID or levobunolol 0.5% BID, and/or acetazolamide 125 to 250 mg PO q6h or methazolamide 25 to 50 mg PO BID (2,3)[B]
  - Bandage contact lens: Lenses with high oxygen permeability and hydrophilic properties aid in epithelial migration/adhesion and basement membrane regeneration (3,4)[B].

- Precautions
– Timolol and levobunolol: history of cardiac/pulmonary disease including bradycardia and asthma/COPD
– Acetazolamide and methazolamide: history of nephrolithiasis or metabolic acidosis
– Mannitol: history of heart failure, renal failure, or sickle cell anemia
– Scopolamine: history of urinary retention
– Ascorbic acid: history of renal impairment
– Tetracycline/doxycycline: Avoid systemic use in children <8 years old and pregnant patients.

– Topical corticosteroids must be used with caution in the presence of damaged corneal epithelium because iatrogenic infection can occur. Use of corticosteroids >6 days may inhibit repair and cause corneoscleral melt (1)[B]. Daily follow-up or consultation with an ophthalmologist is recommended.

Consider adjunctive treatments.
– Biologic fluids with consultation to ophthalmology: umbilical cord serum 20% q2–3h, autologous serum 20% q2–3h, platelet-rich plasma q2–3h, or amniotic membrane suspension 30–50% q1h. These consist of growth factors, vitamins, cytokines, and anti-inflammatory factors to improve dry eyes, reduce pain, and persistent epithelial defects, recurrent erosion syndrome, and neurotrophic ulcers (1,2)[B],(6).

SURGERY/OTHER PROCEDURES
– Goal of subacute treatment is restoration of the normal ocular surface anatomy, control of glaucoma, and restoration of corneal clarity.
– Surgical options include the following:
  – Debridement of necrotic tissue and inflammatory debris (1,4)[A]
  – Conjunctival/tenon advancement (tenoplasty) to restore vascularity in severe burns
  – Tissue adhesive (e.g., cyanoacrylate) for impending or actual corneal perforation
    o Tectonic keratoplasty for acute perforation >1 mm
  – Limbal autograft transplantation for epithelial stem cell restoration
  – Amniotic membrane transplantation or umbilical cord serum drops to promote faster epithelial regeneration and improvement in visual acuity (1)[B]
  – Conjunctival or mucosal membrane transplant to restore ocular surface in severe injury

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Based on ophthalmologic consultation, therapy compliance assessment, and concomitant burn injuries

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
– Depending on severity of ocular injury
  – From daily to weekly visits initially
– May be inpatient if concern for non-compliance or pediatric
– If on mannitol or prednisone, consider frequent serum electrolytes.

PATIENT EDUCATION
● Safety glasses
● Need for immediate ocular irrigation with water following ocular chemical exposure

PROGNOSIS
● Depends on severity of initial injury: Increased limbal involvement in clock hours and greater percentage of conjunctival involvement correlate with poorer prognosis (Dua classification system).
● For mildly injured eyes, complete recovery is common.
● For severely injured eyes, permanent loss of vision is not uncommon.

COMPLICATIONS
● Orbital compartment syndrome
● Persistent epitheliopathy
● Keratoconjunctivitis sicca (dry eye)
● Fibrovascular pannus
● Corneal ulcer/perforation
● Corneal scarring
● Progressive symblepharon
● Neurotrophic keratitis
● Cicatricial ectropion/entropion
● Glaucoma
● Cataract
● Hypotony
● Phthisis bulbi
● Blindness

REFERENCES

SEE ALSO
Burns
CODES

ICD10
- T26.50XA Corrosion of unsp eyelid and periocular area, init encntr
- T26.60XA Corrosion of cornea and conjunctival sac, unsp eye, init
- S05.00XA Inj conjunctiva and corneal abrasion w/o fb, unsp eye, init

CLINICAL PEARLS
- Prompt irrigation of all chemical burns, even prior to arrival to the emergency department, is essential to ensure the best outcomes.
- All patients with ocular chemical injuries should have urgent ophthalmology evaluation.
ONYCHOMYCOSIS
Lauren M. Simon, MD, MPH

BASICS

DESCRIPTION
- Fungal infection of fingernails/toenails
- Caused mostly by dermatophytes but also yeasts and nondermatophyte molds
- Toenails are more commonly affected than fingernails.
- System(s) affected: skin, exocrine
- Synonym(s): tinea unguium; ringworm of the nail

EPIDEMIOLOGY

Prevalence
- Occurs in 2–10% of general population
- Predominant age: 20% in adults >60 years of age
- Rare before puberty
- Prevalence 15–40% in persons with human immunodeficiency infection (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Dermatophytes: Trichophyton (Trichophyton rubrum most common), Epidermophyton, Microsporum
- Yeasts: Candida albicans (most common), Candida parapsilosis, Candida tropicalis, Candida krusei
- Molds: Scopulariopsis brevicaulis, Hendersonula toruloidea, Aspergillus sp., Alternaria tenuis, Cephalosporium, Scytalidium hyalinum
- Dermatophytes cause 90% of toenail and most of fingernail onychomycoses.
- Fingernail onychomycosis is more often caused by yeasts, especially Candida.
- Dermatophytes can invade normal keratin, whereas nondermatophyte molds invade altered keratin (dystrophic/injured nails).

RISK FACTORS
- Older age
- Tinea pedis
- Occlusive footwear
- Cancer/diabetes/psoriasis
- Peripheral vascular disease
- Cohabitation with others with onychomycosis
- Immunodeficiency
- Communal swimming pools
- Smoking
- Peripheral vascular disease
- History of nail trauma
- Autosomal dominant genetic predisposition

COMMONLY ASSOCIATED CONDITIONS
• Immunodeficiency/chronic metabolic disease (e.g., diabetes)
• Tinea pedis/manuum

**DIAGNOSIS**

**PHYSICAL EXAM**

• Dermatophytes: commonly preceded by dermatophyte infection at another site; 80% involve toenails, especially hallux; simultaneous infection of fingernails and toenails is rare. Five clinical forms occur.
  – Distal/lateral subungual onychomycosis (most common): mainly due to T. rubrum. Spreads from distal/lateral margins to nail bed to nail plate; subungual hyperkeratosis; onycholysis; nail dystrophy; discoloration—yellow-white or brown-black, yellow streaking laterally; can progress proximally, bois vermoulu (“worm-eaten wood”); onychomadesis
  – Proximal subungual onychomycosis (rare <1% of cases): hands/feet; leukonychia—begins at proximal part of nail plate, appearing to occur from the proximal underside of the nail (or direct invasion of the nail plate from above); spreads to nail plate and lunula; seen with immunosuppressive conditions
  – Superficial (formerly known as superficial white onychomycosis) about 10% of cases: hallux is preferentially affected; infection of outer surface of nail plate; opaque white spots on nail plate eventually merge to involve entire surface of the nail; most commonly due to Trichophyton mentagrophytes
  – Endonyx onychomycosis involves interior of nail plate, sparing nail bed. Nail develops milky white appearance with indentations. Subungual hyperkeratosis is absent.
  – Totally dystrophic onychomycosis causes complete destruction of nail plate by fungus, resulting in thickened and ridged nail bed covered with keratotic debris.

• Candidal
  – Hands, 70%, especially for the dominant hand
  – Middle finger is most common.
  – Pain is mild, unless secondarily infected.
  – Increases on prolonged contact with water
  – Primarily affects tissue surrounding nail
  – Begins with cuticle detachment
  – White or white-yellow nail discoloration
  – Secondary ungual changes: convex, irregular, striated nail plate with dull, rough surface
  – Onycholysis, especially on hands
  – Distal subungual onychomycosis may occur.
  – Primary involvement of the nail plate is uncommon (thin, crumbly, opaque, brownish nail plate deformed by transverse grooves).
  – Periungual edema/erythema may occur (club-shaped, bulbous fingertips).

• Molds (nondermatophyte)
  – More common in those >60 years of age
  – More common in nails of hallux
  – Resembles distal and lateral onychomycosis

**Pediatric Considerations**

• Candidal infection presents more commonly as superficial onychomycosis.
The U.S. Food and Drug Administration (FDA) has not approved any systemic antifungal agents for treatment of onychomycosis in children. Efficacy and safety profiles in children for some systemic antifungals are similar to those previously reported in adults (2).

DIFFERENTIAL DIAGNOSIS
- Psoriasis (most common alternate diagnosis)
- Traumatic dystrophy
- Lichen planus
- Onychogryphosis (“ram’s horn nails”)
- Eczematous conditions
- Hypothyroidism
- Drugs and chemicals
- Yellow nail syndrome
- Neoplasms (0.7–3.5%) of all melanoma cases are subungual. In a brownish yellow nail, if dark pigment extends into periungual skin fold, consider subungual melanoma.

DIAGNOSTIC TESTS & INTERPRETATION
- Accurate diagnosis requires both laboratory and clinical evidence.
- About 50% of nail dystrophy seen on visual inspection is not fungal in origin, so laboratory assessment improves diagnostic accuracy.
- If onychomycosis is suspected clinically and initial diagnostic laboratory tests are negative, the tests should be repeated.
- A nail plate biopsy or partial/full removal of nail with culture is needed to diagnose proximal subungual onychomycosis.

Initial Tests (lab, imaging)
- Direct microscopy with potassium hydroxide (KOH) preparation (1)[C]
  - Clean nail with 70% isopropyl alcohol.
  - Using sterile clippers, remove diseased, discolored nail plate.
  - Collect debris from stratum corneum of most proximal area (beneath nail or crumbling nail itself) with 1-mm curette/scalpel.
  - Place sample on microscope slide with drop of 5–10% KOH. View after 5 minutes.
  - Gentle heat applied to slide can enhance keratin breakdown.
  - High sensitivity if >2 preparations were examined
  - Look for hyphae, pseudohyphae, or spores.
- Cultures: False-negative finding in 30% (secondary to loss of dermatophyte viability; improved by immediate culture on Sabouraud cell culture medium); results may take 3 to 6 weeks.
- In office dermatophyte test, medium culture indicates dermatophyte growth with yellow-to-red color change of the medium; results in 3 to 7 days; limited studies
- Histologic examination of nail clippings/nail plate punch biopsy: proximal lesions; stain both with periodic acid–Schiff (PAS) stain (1)[C].
- KOH-treated nail clipping stained with PAS: significantly higher rates of detection of onychomycosis as compared with standard methods of KOH preparation and fungal culture (3)[C]
- Polymerase chain reaction (PCR) increases sensitivity of detection of dermatophytes in nail specimen; results available within 3 days can be used as complementary to direct microscope
exam and fungal culture; not widely available

- Fluorescence microscopy can be used as a rapid screening tool for identification of fungi in nail specimens.
- Commercial laboratories may use KOH with calcofluor white stain to improve view of fungal elements in fluorescent microscopy.
- Discontinue all topical medication for at least 1 week before obtaining a sample.

**Test Interpretation**
Pathogens within the nail keratin

---

**TREATMENT**

**GENERAL MEASURES**

- Avoid factors that promote fungal growth (i.e., heat, moisture, occlusion, tight-fitting shoes).
- Treat underlying disease risk factors.
- Treat secondary infections.

**MEDICATION**

**Pregnancy Considerations**
Oral antifungals and ciclopirox are pregnancy Category B (terbinafine, ciclopirox) or C (itraconazole, fluconazole, and griseofulvin). Griseofulvin is not advised in pregnancy due to risks of teratogenicity and conjoined twins. Ideally postpone treatment of onychomycosis until after pregnancy.

**First Line**

- Oral antifungals are preferred due to higher rates of cure but have systemic adverse effects and many drug–drug interactions.
- **Terbinafine**: 250 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails; most effective in cure and prevention of relapse compared with other antifungals and with itraconazole pulse in meta-analysis for toenail onychomycosis (4)[A]
- **Itraconazole pulse**: 200 mg PO BID for 1 week and then 3 weeks off, repeat for two cycles for fingernails and three to four cycles for toenails; does not need to monitor liver function tests (LFTs) with pulse dosing
- **Itraconazole continuous**: 200 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails (less effective than itraconazole pulse for dermatophytes, more effective than terbinafine for Candida and molds)

**Second Line**

- **Fluconazole pulse**: 150 to 300 mg PO weekly for 6 months (lower cure rate); not FDA-approved for onychomycosis
- **Griseofulvin**: 500 to 1,000 mg/day PO for up to 18 months (lower cure rate, continue until the diseased nail is replaced)
- **Posaconazole**: 100, 200, or 400 mg once daily for 24 weeks; 400 mg once daily for 12 weeks; higher cost
- **Topical agents**: Use limited to disease not involving the lunula (proximal nail plate). Topical therapy does not cause systemic toxicity but is less effective than oral therapy. Head-to-head comparison of efficacy of available agents is generally not available.
Efinaconazole solution 10%, apply directly to affected nails once daily for 48 weeks; complete or almost-complete cure after 48 weeks in range of 15–18% (NNT compared to vehicle 7 to 10).

Ciclopirox: 8% nail lacquer (available generically): Apply once daily to affected nails (if without lunula involvement) for up to 48 weeks; remove lacquer with alcohol every 7 days, and then file away loose nail material and trim nails (low-cure rate, avoids systemic adverse effects, less cost-effective). Application after PO treatment may reduce recurrences; systematic review >60% failure rate after 48 weeks of use (5)[A].

Tavaborole 5% solution, a topical oxaborole antifungal, is indicated for onychomycosis of the toenails due to T. rubrum or T. mentagrophytes; complete or almost-complete cure 15–18% after 48 weeks (NNT compared to vehicle approximately 7).

Contraindications for oral antifungals
- Hepatic disease
- Pregnancy (see “Pregnancy Considerations”)
- Current/history of congestive heart failure (CHF) (itraconazole)
- Ventricular dysfunction (itraconazole)
- Porphyria (griseofulvin)

Precautions/adverse effects
- Oral antifungals
  - Hepatotoxicity/neutropenia
  - Hypersensitivity
  - Photosensitivity, lupus-like symptoms, proteinuria (griseofulvin)
  - Chronic kidney disease (Avoid terbinafine for patients with creatinine clearance [CrCl] <50 mL/min, decrease fluconazole dose.)
  - CHF, peripheral edema, pulmonary edema (itraconazole)
  - Rhinitis (itraconazole)

Ciclopirox topical: side effects: rash, nail disorders; avoid contact with skin except along nail edge; caution with broken skin or vascular compromise

Oral agents: numerous significant drug–drug interactions; need to check each medication:
- Terbinafine (inhibits cytochrome P450 2D6 [CYP2D6] isoenzyme): for example, β-blockers, monoamine oxidase inhibitors (MAOIs), SSRIs, tricyclic antidepressants (TCAs), warfarin, oxycodone
- Itraconazole (inhibit CYP3A4): for example, antiarrhythmics, benzodiazepines, ergot alkaloids, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, calcium channel blockers, corticosteroids, hydrochlorothiazide, hypoglycemics, oral contraceptives (OCPs), warfarin, zolpidem
- Griseofulvin: for example, OCPs, salicylates, warfarin

Surgery/Other Procedures
- Nail débridement to remove infected keratin (efficacy not well studied): Use for few nails involved or if not, for candidate of systemic therapy.
  - Mechanical: Soften with occlusive dressing with 40% urea gel; detach from nail bed with tweezers, file with abrasive stone or curette.
  - Chemical: Protect peripheral tissue with adhesive strips; apply ointment of 30% salicylic acid, 40% urea, or 50% potassium iodide under occlusive dressing.
  - Débridement may be combined with topical antifungal therapy.
  - Surgical avulsion if few nails are involved; for pain control.
Laser treatment has shown some positive results but poor statistical power and limited efficacy or safety data (6)[A].

Photodynamic therapy using topical photosensitizing agents and irradiation with appropriate light source some success for treatment of superficial nail infections; limited data

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Melaleuca alternifolia (tea tree oil) Cochrane review found no evidence of benefit (5)[A].
- Vicks VapoRub application to nails daily for 48 weeks has been found safe, but efficacy is uncertain.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Formation of a new fingernail takes 4 to 6 months, and a new toenail takes 12 to 18 months.
- Cure defined as:
  - Clinical cure, 100% absence of clinical signs, and/or
  - Mycotic cure, negative mycology with ≥1 of the following clinical signs:
    - Distal subungual hyperkeratosis/onycholysis leaving <10% of the nail plate affected
    - Nail plate thickening that does not improve with treatment because of comorbid condition

**Patient Monitoring**

- Topical agents: Slow response is expected; visits every 6 to 12 weeks
- Terbinafine, griseofulvin: baseline, and as needed, LFTs and CBC
- Itraconazole continuous: baseline, and as needed, LFTs

**PATIENT EDUCATION**

- Advise patient to:
  - Keep affected area clean and dry.
  - Avoid rubber/other occlusive, tight-fitting footwear.
  - Wear absorbent cotton socks.
  - Launder clothing and towels frequently in hot water.
  - Avoid sharing nail implements or use on both normal and abnormal nails.
- Cure of all toenails may not be attainable.
- Nails may not appear normal after cure.

**PROGNOSIS**

- Complete clinical cure in 25–50% (higher mycologic cure rates) with oral therapy
- Recurrence is 10–50% (relapse/reinfection).
- Poor prognostic factors
  - Areas of nail involvement >50%
  - Significant proximal/lateral disease
  - Subungual hyperkeratosis >2 mm
  - White/yellow or orange/brown streaks in the nail (includes dermatophytoma)
  - Total dystrophic onychomycosis (with matrix involvement)
  - Nonresponsive organisms (e.g., Scytalidium mold)
  - Patients with immunosuppression
  - Diminished peripheral circulation
COMPLICATIONS

- Secondary infections with progression to soft tissue infection/osteomyelitis
- Toenail discomfort/pain that can limit physical mobility or activity
- Anxiety, negative self-image

REFERENCES

CODES

ICD10

- B35.1 Tinea unguium
- B37.2 Candidiasis of skin and nail

CLINICAL PEARLS

- Psoriasis and chronic nail trauma are commonly mistaken for fungal infection.
- Diagnosis should be based on both clinical and mycologic laboratory evidence.
OPTIC NEURITIS
Olga Cerón, MD ● Pablo I. Hernandez Itriago, MD, MHCM, FAAFP

BASICS

DESCRIPTION
- Inflammation of the optic nerve (cranial nerve II)
- Most common form is acute demyelinating optic neuritis (ON), but other causes include infectious disease and systemic autoimmune disorders.
- Optic disc may be normal in appearance at onset (retrobulbar ON, 67%) or swollen (papillitis, 33%).
- Key features:
  - Abrupt visual loss (typically monocular)
  - Periorbital pain with eye movement (90%)
  - Pain in the distribution of the first division of the trigeminal nerve
  - Dyschromatopsia: color vision deficits
  - Relative afferent pupillary defect (RAPD)
- Usually unilateral in adults; bilateral disease more common in children
- Presenting complaint in 25% of patients with multiple sclerosis (MS)
- In children, headaches are common.
- System(s) affected: nervous
- Synonym(s): papillitis, demyelinating optic neuropathy; retrobulbar ON

EPIDEMIOLOGY

Incidence
- 5/100,000 cases per year
- More common in northern latitudes
- More common in spring season
- More common in whites than in other races
- Predominant age: 18 to 45 years; mean age 30 years
- Predominant sex: female > male (3:1)

ETIOLOGY AND PATHOPHYSIOLOGY
- In both MS-associated and isolated monosymptomatic ON, the cause is presumed to be a demyelinating autoimmune reaction.
- Possible mechanisms of inflammation in immune-mediated ON are the cross-reaction of viral epitopes and host epitopes and the persistence of a virus in CNS glial cells.
- Neuromyelitis optica (NMO) IgG autoantibody, which targets the water channel aquaporin-4
- Primarily idiopathic
- MS
- Viral infections: measles, mumps, varicella-zoster, coxsackievirus, adenovirus, hepatitis A and B, HIV, herpes simplex virus, cytomegalovirus
- Nonviral infections: syphilis, tuberculosis, meningococcus, cryptococcosis, cysticercosis, bacterial sinusitis, Streptococcus B, Bartonella, typhoid fever, Lyme disease, fungus
- Systemic inflammatory disease: sarcoidosis, systemic lupus erythematosus, vasculitis
Local inflammatory disease: intraocular or contiguous with the orbit, sinus, or meninges
Toxic: lead, methanol, arsenic, radiation
Vascular lesions affecting the optic nerve
Posterior uveitis (i.e., birdshot retinochoroidopathy, toxoplasmosis, toxocariasis)
Tumors
Medications: ethambutol, chloroquine, isoniazid, chronic high-dose chloramphenicol, tumor necrosis factor α-antagonist, infliximab (Remicade), adalimumab (Humira), etanercept (Enbrel)

COMMONLY ASSOCIATED CONDITIONS
MS (common): ON is associated with an increased risk of MS.
Other demyelinating diseases: Guillain-Barré syndrome, Devic NMO, multifocal demyelinating neuropathy, acute disseminated encephalomyelitis

DIAGNOSIS

HISTORY
Decreased visual acuity, deteriorating in hours to days, usually reaching lowest level after 1 week
Usually unilateral but can also be bilateral
Brow ache, globe tenderness, deep orbital pain exacerbated by eye movement (92%)
Retro-orbital pain may precede visual loss.
Desaturation of color vision (dull or faded colors), especially red tones
Apparent dimness of light intensities
Impairment of depth perception (80%); worse with moving objects (Pulfrich phenomenon)
Transient increase in visual symptoms with increased body temperature and exercise (Uhthoff phenomenon)
Phosphenes: fleeting colors and flashes of light (30%)
May present with a recent flulike viral syndrome
Detailed history and review of systems, looking for a history of demyelinating, infectious, or systemic inflammatory disease

PHYSICAL EXAM
Complete general exam, full neurologic exam, and ophthalmologic exam (with vision testing) looking for the following:
Decreased visual acuity and color perception
Central, cecocentral, arcuate, or altitudinal visual field deficits
Papillitis: (1/3) swollen disc ± peripapillary flame-shape hemorrhage or often (2/3) normal disc exam
Temporal disc pallor seen later at 4 to 6 weeks (1)[A]
RAPD: The pupil of the affected eye dilates with a swinging light test unless disease is bilateral.

DIFFERENTIAL DIAGNOSIS
Demyelinating disease, especially MS
Myelin oligodendrocyte glycoprotein-antibody disease (MOG-AD)
Infectious/systemic inflammatory disease
Neuroretinitis: virus, toxoplasmosis, Bartonella
Toxic or nutritional optic neuropathy
Acute papilledema (bilateral disc edema)
Compression:
- Orbital tumor/abscess compressing the optic nerve
- Intracranial tumor/abscess compressing the afferent visual pathway
- Orbital pseudotumor
- Carotid–ophthalmic artery aneurysm
Temporal arteritis or other vasculitides
Trauma or radiation
NMO (Devic disease)
Anterior ischemic optic neuropathy
Leber hereditary optic neuropathy
Kjer-type autosomal dominant optic atrophy
Severe systemic hypertension
Diabetic papillopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- In typical presentations, erythrocyte sedimentation rate (ESR) is standard, but other labs are unnecessary. Antinuclear antibodies (ANAs), angiotensin-converting enzyme (ACE) level, fluorescent treponemal antibody absorption (FTA-ABS), and chest x-ray (CXR) have been shown to have no value in typical cases [1,2][A].
- In atypical presentations, including absence of pain, a very swollen optic nerve, >30 days without recovery, or retinal exudates, labs may be indicated to rule out underlying disorders:
  - CBC
  - ANA test
  - Rapid plasma reagin (RPR) test
  - FTA-ABS test
- MRI of brain and orbits to evaluate risk of etiology of ON from MS: thin cuts (2 to 3 mm) gadolinium-enhanced and fat-suppression images to look for Dawson fingers of MS (periventricular white matter lesions oriented perpendicular to the ventricles) and also to look for enhancement of the optic nerve: baseline MRI provides prognostic information for MS and assists in stratifying risk of development of MS depending on absence or presence of white matter lesions in brain.
- MRI of the brain: T2 fluffy hyperintense lesions in MOD-AD
- MRI of the brain: T2 hyperintense lesions around the 3rd and 4th ventricle and the aqueduct of Sylvius in NMO
- Lumbar puncture (LP): to evaluate cerebrospinal fluid (CSF) composition and oligoclonal bands (OCBs)
- CT scan of chest to rule out sarcoidosis if clinical suspicion is high
- Optical coherence tomography (OCT) of the retinal nerve fiber layer (RNFL), a noninvasive imaging technique of the optic nerve, may serve as a diagnostic tool to quantify thickness of the nerve fiber layer objectively and, thus, monitor structural change (axonal loss) of the optic nerve in the course of the disease.

**Follow-Up Tests & Special Considerations**
Visual field test (Humphrey 30–2) to evaluate for visual field loss: diffuse and central visual loss more predominant in the affected eye at baseline (1)[A]

OCT of the optic nerve RNFL to detect and monitor axonal loss in the anterior visual pathways (3)[C]

Low-contrast visual acuity (as a measure of disease progression)

A blood test serum marker: NMO-IgG checks for antibodies for NMO

**Diagnostic Procedures/Other**

- In atypical cases, including bilateral deficits, young age, or suspicion of infectious etiology, lumbar puncture (LP) with neurology consultation is indicated.
- LP for suspected MS is a physician-dependent decision. Some studies indicate that it may not add value to MRI for MS detection (1)[A], but no consensus on the subject exists.

**TREATMENT**

Most persons with ON recover spontaneously.

**MEDICATION**

**First Line**

- IV methylprednisolone has been shown to speed up the rate of visual recovery but without significant long-term benefit; consider for patients who require fast recovery (i.e., monocular patients or those whose occupation requires high-level visual acuity). For significant vision loss, parenteral corticosteroids may be considered on an individualized basis. Optic Neuritis Treatment Trial (ONTT):
  - Observation and corticosteroid treatment are both acceptable courses of action.
  - High-dose IV methylprednisolone (250 mg q6h for 3 days) followed by oral corticosteroids (1 mg/kg/day PO for 11 days, taper over 1 to 2 weeks) (2,4)[A]

- Others use IV Solu-Medrol infusion (1 g in 250 mL D₅ 1/2 normal saline infused over 1 hour daily for 3 to 5 days):
  - No evidence of long-term benefit (4)[A]
  - May decrease recovery time (4)[A]
  - May decrease risk of MS at 2 years but not 5 years (4)[A]

- Give antiulcer medications with steroids.
- Discuss benefits and potential side effects of corticosteroids with patient (i.e., weight gain, osteoporosis, mood changes, gastrointestinal disturbances, hyperglycemia, insomnia).

**ALERT**

NEVER use oral prednisone alone as the primary treatment because this may increase the risk for recurrent ON.

**Second Line**

- Disease-modifying agents, such as interferon-β1a (IFN-β1a; Avonex, Rebif) and IFN-β1b (Betaseron), are used to prevent or delay the development of MS in people with ON who have ≥2 brain lesions evident on MRI (5)[B].
  - These medications have been proposed for use in patients with one episode of ON (clinically isolated syndrome) at high risk of developing MS (1+ lesion on brain MRI).
Decisions should be made individually with neurology consultation.

SOLIRIS® (Eculizumab) is FDA approved for neuromyelitis optica spectrum disorder (NMOSD) in patients who who are anti-aquaporin-4 (AQP4) antibody positive. The most common symptoms of NMOSD are optic neuritis and transverse myelitis (6)[B].

**Pediatric Considerations**

- Optic disc swelling and bilateral disease are more common in children.
- No systematic study defining high-dose corticosteroids in children with pediatric optic neuritis (PON) have been conducted (7)[C].
  - Consensus recommends: 3 to 5 days of IV methylprednisolone (4 to 30 mg/kg/day), followed by a 2- to 4-week taper of oral steroids (7)[C].
  - Tailor along with chronic immunotherapy for the associated conditions (MS, AQP4+NMOSD, and MOG+AD) (8)[C].
- Consider infectious and postinfectious causes of optic nerve impairment.

**ISSUES FOR REFERRAL**

Referral to a neurologist and/or ophthalmologist

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Monthly follow-up to monitor visual changes and steroid side effects

**PATIENT EDUCATION**

- Provide reassurance about recovery of vision.
- If the disease is believed to be secondary to demyelinating disease, patient should be informed of the risk of developing MS.
  - [http://www.nanosweb.org/files/Patient%20Brochures/English/OpticNeuritis_English.pdf](http://www.nanosweb.org/files/Patient%20Brochures/English/OpticNeuritis_English.pdf)
    (available in other languages)

**PROGNOSIS**

- Orbital pain usually resolves within 1 week.
- Visual acuity:
  - Rapid spontaneous improvement at 2 to 3 weeks and continues for several months (may be faster with IV corticosteroids)
  - Often returns to normal or near-normal levels (20/40 or better) within 1 year (90–95%), even after near blindness
- Other visual disturbances (e.g., contrast sensitivity, stereopsis) often persist after acuity returns to normal.
- Recurrence risk of 35% within 10 years: 14% affected eye, 12% contralateral, 9% bilateral; recurrence is higher in MS patients (48%).

**COMPLICATIONS**

Permanent loss of vision
REFERENCES

SEE ALSO

Multiple Sclerosis

CODES

ICD10

- H46.9 Unspecified optic neuritis
- H46.00 Optic papillitis, unspecified eye
- H46.10 Retrobulbar neuritis, unspecified eye

CLINICAL PEARLS

- MRI is the procedure of choice for determining relative risk and possible therapy for MS prevention.
- The ONTT showed that high-dose IV methylprednisolone followed by oral prednisone accelerated visual recovery but did not improve the 6-month or 1-year visual outcome compared with placebo, whereas treatment with oral prednisone alone did not improve the outcome and was associated with an increased rate of recurrence of ON.
OSGOOD-SCHLATTER DISEASE (TIBIAL APOPHYSITIS)
David P. Sealy, MD ● Robert J. Tiller, MD, FAAFP

BASICS

DESCRIPTION
- Osgood-Schlatter disease (OSD) is a syndrome associated with traction apophysitis and patellar tendinosis that is most common in adolescent boys and girls.
  - Patients present with pain and swelling of the anterior tibial tubercle.
- System(s) affected: musculoskeletal
- Synonym: tibial tubercle apophysitis

EPIDEMIOLOGY

Incidence
Incidence in girls increasing with increased participation in organized youth sports; still more common in boys

Prevalence
- A common apophysitis in childhood and adolescence affecting athletes (21%) and nonathletes (4.5%) (1)
- Approximately 10% remain symptomatic as adults (2).
- 10% of all adolescent knee pain is due to OSD.

ETIOLOGY AND PATHOPHYSIOLOGY

Traction apophysitis of the tibial tubercle due to repetitive strain on the secondary ossification center of the tibial tuberosity, concurrent patellar tendinosis, and disruption of the proximal tibial apophysitis
- Basic etiology unknown, exacerbated by exercise
  - Jumping and pivoting sports place highest strain on the tibial tubercle. Repetitive trauma is the most likely inciting factor.
- Possible association with tight hip flexors and tight quadriceps; increased quadriceps strength in adolescence relative to hamstring strength
- Early sports specialization increases the risk for OSD 4-fold (3)[B].

RISK FACTORS

- Affects children and adolescents most commonly from the ages of 8 to 18 years
  - Girls 8 to 14 years
  - Boys 10 to 18 years
- OSD is slightly more common in boys.
- Rapid skeletal growth
- Increased weight
- Quadriceps tightness
- Participation in repetitive-jumping sports and sports with heavy quadriceps activity (football, volleyball, basketball, hockey, soccer, skating, gymnastics)
- Ballet (2-fold risk compared with nonathletes)
GENERAL PREVENTION
- Avoid sports with heavy quadriceps loading (especially deceleration activities—eccentric loading).
- Patients may compete if pain is minimal.
- Increase hamstring and quadriceps flexibility.
- Possibly reduce sports specialization

COMMONLY ASSOCIATED CONDITIONS
- Shortened (tight) rectus femoris found in 75% with OSD
- Possible association with ADD/ADHD; adolescents with ADD/ADHD are at risk for other musculoskeletal injuries.
- Sinding-Larsen-Johansson apophysitis

DIAGNOSIS

HISTORY
- Unilateral or bilateral (30%) pain of the tibial tuberosity
- Pain exacerbated by exercise, especially jumping and landing after jumping
- Pain upon kneeling on the affected side(s)
- Antalgic or straight-legged gait

PHYSICAL EXAM
- Knee pain with squatting or crouching
- Absence of effusion or condyle tenderness
- Tibial tuberosity swelling and tenderness
- Pain increased with resisted knee extension or kneeling
- Erythema over tibial tuberosity
- Functional testing: Single-leg squat (SLS) and standing broad jump reproduce pain (3).

DIFFERENTIAL DIAGNOSIS
- Stress fracture of the proximal tibia
- Pes anserinus bursitis
- Quadriceps tendon avulsion
- Patellofemoral stress syndrome
- Chondromalacia patellae (retropatellar pain)
- Proximal tibial neoplasm
- Osteomyelitis of the proximal tibia
- Tibial plateau fracture
- Sinding-Larsen-Johansson syndrome (patellar apophysitis)—pain over inferior patellar tendon
- Patellar fracture or stress fracture
- Infraapatellar bursitis
- Patellar tendinitis—pain over inferior patellar tendon and inferior pole of patella
- Osteochondroma of the tibial tubercle
- Tibial tuberosity fracture
- Patellar tendon lipoma
- Osteochondromas
Osteochondritis dissecans
Iliotibial band syndrome
Hoffa disease (infrapatellar fat pad syndrome)
Saphenous neuritis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Generally a clinical diagnosis. No tests are indicated unless other diagnoses are under consideration.
- Radiographic imaging of the proximal tibia and knee may show heterotopic calcification in the patellar tendon:
  - X-rays are rarely diagnostic, but appearance of a separate fragment at the tibial tuberosity identifies candidates for potential surgical intervention.
  - Calcified thickening of the tibial tuberosity with irregular ossification at tendon insertion on the tibial tubercle (4)[B]

**Diagnostic Procedures/Other**
- Bone scan may show increased uptake in the area of the tibial tuberosity:
  - Increased uptake in apophysitis is normal in children, but with OSD, there may be more uptake on the opposite side.
- Ultrasound is an excellent alternative, showing thickening of the distal patellar tendon and infrapatellar bursa effusion.
- MRI shows fragmentation of the tibial tubercle and hyperintense T2 signal of the apophysis and patellar tendon insertion.

**Test Interpretation**
Biopsy is not necessary but would show osteolysis and fragmentation of the tibial tubercle.

**TREATMENT**

**GENERAL MEASURES**
- Frequent ice applications 2 to 3 times per day for 15 to 20 minutes
- Rest and activity modification—avoid activities that increase pain and/or swelling.
- Physical therapy helps with hamstring and quadriceps strengthening and stretching.
- Open- and closed-chain eccentric quadriceps strengthening
- Avoid aggressive stretching if pain is significant to avoid risk of tibial tubercle avulsion (1)[B].
- Consult orthopedic surgery for tibial tuberosity fracture or complete avulsion.
- Electrical stimulation and iontophoresis may be beneficial (1)[B].
- Patients with marked pronation may benefit from orthotics.
- A single study showed benefit from an infrapatellar strap, and many experts recommend the use of a knee brace with an H- or U-shaped buttress (1)[C].

**MEDICATION**
**First Line**
- Any analgesic may be considered.
NSAIDs may help control pain.
Opioids are not recommended as first line.

Second Line
More potent analgesics, such as opioids, may ONLY be considered for short-term use in extreme situations.
Corticosteroid injections are not recommended.
Hypertonic glucose and/or Xylocaine injections have shown recent benefit (5)[C].
Autologous platelet injections (PRP) have shown benefit in one study (6)[C].
Acupuncture

ISSUES FOR REFERRAL
When conservative therapy is unsuccessful and symptoms persist into adulthood, consider surgical referral.

SURGERY/OTHER PROCEDURES
- Débridement of a thickened, cosmetically unsatisfactory tibial tubercle (rare) or removal of mobile heterotopic bone
- Surgical excision of a painful tibial tubercle is rarely needed (<5%) and may be successfully done with bursoscopy instead of an open procedure (4)[C].
- Recent report of successful pain elimination in OSD with percutaneous screw fixation of the tibial tuberosity (2)[C]
- Reduction wedge osteotomy has been recently reported as 100% successful in a small case series (6)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Athletes may return to play if pain is controlled.
- Presence of pain does not preclude competition.

Patient Monitoring
With worsening of symptoms only

PATIENT EDUCATION
- Avoid jumping sports or reduce activities that increase pain and swelling.
- Assure family that symptoms and findings will diminish with time and rest.
- Patients can safely play sports with mild pain.
- Quadriceps stretching and strengthening are important.
- Surgical options are rarely needed, but good results can be expected.

PROGNOSIS
- Except in rare cases, this is a self-limiting illness that resolves within 2 years of full skeletal maturation.
- 10% of patients with OSD as adolescents will have symptoms in adulthood. Up to 60% of adults with prior OSD report occasional symptoms and pain with kneeling.
- Most patients with OSD have residual “knots” of tibial tubercles that never completely resolve.
COMPLICATIONS

- Rarely, a heavily fragmented and inflamed tibial ossicle will avulse and require surgery.
- Rare complications in adulthood include pseudarthrosis of the tibial tubercle, genu recurvatum, patella alta, and ossicle fragmentation possibly leading to osteoarthritis of the knee.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- M92.50 Juvenile osteochondrosis of tibia and fibula, unsp leg
- M92.51 Juvenile osteochondrosis of tibia and fibula, right leg
- M92.52 Juvenile osteochondrosis of tibia and fibula, left leg

CLINICAL PEARLS
Infrapatellar pain in an adolescent athlete undergoing a rapid growth spurt is OSD, patellar tendinosis, or Sinding-Larsen-Johansson syndrome.

Always consider lumbar disc disease, osteogenic sarcoma, or hip pathology in the differential diagnosis of OSD.

OSD is generally self-limited. Athletes should modify activity based on pain. Mild pain is not a contraindication to athletic participation.

Treatment focuses on strengthening and stretching of the hamstrings and quadriceps.

10% of adolescents with OSD will be symptomatic as adults.

Persistent employment hampering symptoms in adults often require surgery.
OSTEOARTHRITIS
Patrick Wakefield Joyner, MD, MS

BASICS

DESCRIPTION
- Progressive loss of articular cartilage with reactive changes at joint margins and in subchondral bone
- Primary osteoarthritis (OA)
  - Idiopathic: categorized by clinical features (localized, generalized, erosive)
- Secondary OA
  - Posttraumatic
  - Childhood anatomic abnormalities (e.g., congenital hip dysplasia, slipped capital femoral epiphysis [SCFE], Legg-Calvé-Perthes disease)
  - Inheritable metabolic disorders (e.g., Wilson disease, alkaptonuria, hemochromatosis)
  - Neuropathic arthropathy (Charcot joints)
  - Hemophilic arthropathy
  - Endocrinopathies: acromegalic arthropathy, hyperparathyroidism, hypothyroidism
  - Paget disease
  - Noninfectious inflammatory arthritis (e.g., rheumatoid arthritis [RA], spondyloarthropathies)
  - Gout, calcium pyrophosphate deposition disease (pseudogout)
  - Septic or tuberculous arthritis
  - Femoral acetabular impingement (FAI)
- System(s) affected: musculoskeletal
- Synonym(s): osteoarthrosis; degenerative joint disease (DJD)

EPIDEMIOLOGY
- Most common joint disease in US.
- Symptomatic OA most common in patients >40 years
- Leading cause of disability in patients >65 years
- Predominant sex: male = female
- 90% of hip OA is primary.
- Hip OA is more common in whites.
- Predominantly impacts weight-bearing joints

Prevalence
- >30 million patients affected in US
- Increases with age; radiographic evidence of OA is present in many patients >65 years old.
- Moderate to severe hip OA in 3–6% of whites; <1% in East Indians, blacks, Chinese, and Native Americans

ETIOLOGY AND PATHOPHYSIOLOGY
- Failure of chondrocytes to maintain the balance between degradation and synthesis of extracellular collagen matrix. Collagen loss results in alteration of proteoglycan matrix and increased susceptibility to degenerative change.
Biomechanical, biochemical, inflammatory, and immunologic factors contribute to cartilage loss. Attempts at repair most commonly manifest as osteophyte formation.

Genetics
- Up to 65% of OA may have a genetic component.
- The heritability of end-stage hip OA is up to 27%.
- Twin studies in women show 50% (hip, knee) to 65% (hip) heritability rates of OA.

RISK FACTORS
- Increasing age: >50 years
- Age as a risk factor is greatest for hip and knee OA.
- Hand OA is most common in postmenopausal women.
- Obesity (weight-bearing joints); BMI >35
- Small critical shoulder angle (<30 degrees) can predispose to shoulder OA.
- Trauma, infection, or inflammatory arthritis
- Female gender (knee and hand)

GENERAL PREVENTION
Weight management; regular physical activity

DIAGNOSIS

HISTORY
- Distinguish OA from other types of arthritis by:
  - Absence of systemic findings
  - Minimal articular inflammation
  - Distribution of involved joints (e.g., distal and proximal interphalangeal joints)
- OA characterized by slowly developing joint pain. Pain often described as aching or burning in nature. Anecdotally, many patients describe pain changes with alterations in weather conditions.
- Transient stiffness (especially after awakening in morning and after sitting) that tends to lessen 10 to 15 minutes after joint movement
- OA more commonly affects hands, spine, and large weight-bearing joints (hip, knee).
  - Most common joint in hand is the first carpometacarpal joint of the thumb (patients complain of pain with grip and pinching).

PHYSICAL EXAM
- Joint bony enlargement (Heberden nodes of distal interphalangeal joints; Bouchard nodes of proximal interphalangeal joints)
- Decreased range of motion of affected joints
- Mechanical symptoms (clicking, locking) may be present, especially in knees with degenerative meniscal injury.
- Crepitation is a late sign.
- Local pain and stiffness with OA of spine; radicular pain (if compression of nerve roots)
- Changes in joint alignment (genu varum [bowlegs] and genu valgum [knock-knees])

DIFFERENTIAL DIAGNOSIS
- Crystalline arthropathies (gout, pseudogout): inflammatory arthritides (RA), spondyloarthropathies (reactive arthritis, psoriatic arthritis), septic arthritis
- Fibromyalgia, avascular necrosis, Lyme disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Routine chemistries are not helpful in diagnosis.
- X-rays are usually normal early in disease process.
- As OA progresses, plain films show:
  - Narrowed, asymmetric joint space
  - Osteophyte formation
  - Subchondral bony sclerosis
  - Subchondral cyst formation
- Erosions may occur on surface of distal and proximal interphalangeal joints (erosive OA).
- MRI may particularly demonstrate chondral degeneration and associated meniscal tears. 5–10% weight loss is associated with slowing of arthritic changes and decreased chondral loss on follow-up studies (1).

**Follow-Up Tests & Special Considerations**
- May be useful in monitoring treatment with NSAIDs (renal insufficiency and GI bleeding)
- In secondary OA, abnormal lab results associated with underlying disorder (e.g., hemochromatosis [abnormal iron studies])

**Diagnostic Procedures/Other**
- Joint aspiration (not usually necessary for diagnosis)
  - Can help distinguish OA from other arthritides
  - OA: cell count usually <500 cells/mm³, predominantly mononuclear
  - Inflammatory: cell count usually >2,000 cells/mm³, predominantly neutrophils
  - Birefringent crystals in gout (−) and pseudogout (+)

**Test Interpretation**
- Macroscopic patchy cartilage damage and bony hypertrophy
- Histologic phases:
  - Extracellular matrix edema and cartilage microfissures
  - Subchondral fissuring and pitting
  - Erosion and formation of osteocartilaginous loose bodies
- Subchondral bone trabecular microfractures and sclerosis with osteophyte formation
- Degradation secondary to release of proteolytic and collagenolytic enzymes, prostaglandins, and associated immune response

**TREATMENT**

**GENERAL MEASURES**
- Weight management combined with exercise/physical therapy demonstrates most improvement in patients with OA.
- Physical therapy to maintain or regain joint motion and muscle strength
– Quadriceps-strengthening exercises relieve knee pain and disability.
– Periscapular strengthening and range of motion exercises for shoulder arthritis
– Abductor and core strengthening as well as gait mechanics for hip arthritis
• Transition to non–weight-bearing exercises (i.e., elliptical, stationary bike, swimming)
• Exercise must be maintained; benefits are lost 6 months after exercise cessation.
• Protect joints from overuse; ambulatory aides are beneficial as is proper-fitting footwear.
• Bracing, joint supports, or insoles in patients with biomechanical instability:
  – Bracing is more beneficial in patients with unicompartmental disease of the knee.
• For knee OA in particular, several nonpharmacologic modalities are strongly recommended:
  aerobic, aquatic, and/or resistance exercise and weight loss.
• Nonpharmacologic modalities that are conditionally recommended for knee OA include medial
  wedge insoles for valgus knee OA, subtalar strapped lateral insoles for varus knee OA,
  medially directed patellar taping, manual therapy, walking aids, thermal agents, tai chi, self-
  management programs, and psychosocial intervention.

**MEDICATION**

**First Line**

• Manage pain and inflammation:
  – Acetaminophen up to 1,000 mg TID–QID: effective for pain relief in OA of knee and hip
  – Topical NSAID gels, creams have short-term (<4 weeks) benefits. Topical NSAIDs are a
    core treatment for hand and joints with minimal soft-tissue coverage (i.e., hand) OA.
    Diclofenac gel 1% can be applied as needed up to QID.
  – If acetaminophen or topical NSAIDs are insufficient, consider an oral NSAID/COX-2
    inhibitor. Use the lowest effective dose for the shortest time possible.
  – May use nonacetylated salicylates (e.g., salsalate, choline-magnesium salicylate) or low-
    dose ibuprofen ≤1,600 mg/day
  – Topical NSAIDs and capsaicin as alternatives to oral analgesic/anti-inflammatory
    medications in knee OA
• NSAID contraindications:
  – All PO NSAIDs/COX-2 inhibitors have analgesic effects of a similar magnitude but vary in
    their potential GI and cardiorenal toxicity.
  – NSAIDs should be avoided in patients with renal disease, CHF, HTN, active peptic ulcer
    disease, and previous hypersensitivity to an NSAID or aspirin (asthma, nasal polyps,
    hypotension, urticaria/angioedema).
  – Combination of NSAIDs and full-strength aspirin (325 mg) is contraindicated.
  – In patients at high cardiovascular risk: Combination of a nonselective NSAID and low-dose
    aspirin (81 mg) is recommended.
  – Oral or parenteral corticosteroids are contraindicated.

**ALERT**

• Precautions:
  – If PO NSAID/COX-2 inhibitor use is necessary for a patient aged >65 years or a patient <65
    years with increased GI-bleeding risk factors, proton pump inhibitors are recommended.
  – Significant possible interactions:
- NSAIDs reduce effectiveness of ACE inhibitors and diuretics.
- Aspirin and NSAIDs (except COX-2 inhibitors) may increase effects of anticoagulants.
- Salicylates reduce effectiveness of spironolactone (Aldactone) and uricosurics.
- Corticosteroids and some antacids increase salicylate excretion, whereas ascorbic acid and ammonium chloride reduce salicylate excretion and may cause toxicity.

**Pregnancy Considerations**
- ASA and NSAIDs have reported fetal risk during 1st and 3rd trimesters of pregnancy.
- Compatible with breastfeeding

**Second Line**
- Topical capsaicin is an adjunct therapy for knee and hand OA.
- Topical NSAIDs (e.g., diclofenac gel) can lower gastric and renal risks associated with oral NSAIDs.
- Rubefacients (e.g., oil of wintergreen) are not recommended.
- Physical therapy: Core strengthening for hip OA and knee muscle strengthening for knee OA decrease joint reactive forces and can relieve pain.
- Physical therapy demonstrates minimal benefit compared to sham treatment in randomized trial in patients with severe hip OA (2)[A].
- Bracing; medial and lateral unloader braces are effective; long leg alignment x-rays can help determine the appropriate brace.
- TENS modalities for pain may be more beneficial than hyaluronic acid (HA) injection (3)[A].

**Third Line**
- Intra-auricular corticosteroid injections can be used for acute flares and for patients failing first- and second-line treatments. Minimize injections (~2 per joint per year).
- Long-lasting corticosteroid injections are increasingly available; outcomes have not yet been definitively compared to traditional corticosteroid injections.
- Hyaluronic acid (HA) is safe and improves pain for patients with glenohumeral shoulder osteoarthritis (4)
- Platelet-rich plasma (PRP) is more effective than HA injections for early-stage knee OA (5)[B].
- Bone marrow aspirate concentrate (BMAC) demonstrates good outcomes for patients with mild to moderate knee OA; not recommended for patients with severe knee OA (6)[C].
- TENS is effective for pain relief in large-joint OA.
- Ultrasound improves injection accuracy.
- Cryotherapy in conjunction with physical therapy is more beneficial than physical therapy alone for knee arthritis (7).

**ADDITIONAL THERAPIES**
Address psychosocial factors (i.e., self-efficacy, coping skills). Screen for and appropriately treat anxiety and depression. Improve social support.

**SURGERY/OTHER PROCEDURES**
- Total knee arthroplasty (TKA) may be necessary if conservative management fails.
- Knee arthroscopy is not routinely recommended for the treatment of OA in the absence of clear mechanical symptoms (i.e., locking, clicking, etc.).
COMPLEMENTARY & ALTERNATIVE MEDICINE

- Nutritional supplements (glucosamine and chondroitin sulfate) may benefit some patients and have low toxicity. There is lack of standardized outcome assessments. Trial results using glucosamine and chondroitin have been mixed. If no response is apparent within 6 months, discontinue use.
- TENS, yoga, and acupuncture have shown benefit.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Regularly assess range of motion and functional status.
- Monitor for GI blood loss and cardiac, renal, and mental status in older patients on NSAIDs or aspirin.
- Periodic CBC, renal function tests, stool for occult blood in patients on chronic NSAID therapy

PATIENT EDUCATION

- Arthritis Foundation: http://www.arthritis.org

PROGNOSIS

- Progressive disease: early in course, pain relieved by rest; later, pain may persist at rest and at night.
- Joint effusions and enlargement may occur (especially in knees) as disease progresses.
- Osteophyte (spur) formation, especially at joint margins
- Advanced stage with full-thickness loss of cartilage at which point joint replacement is a consideration

COMPLICATIONS

- Leading cause of musculoskeletal pain and disability
- Decompensated CHF, GI bleeding, decreased renal function on chronic NSAID or aspirin therapy

- M19.212 Secondary osteoarthritis, left shoulder

CLINICAL PEARLS
- Patients with OA typically have morning stiffness lasting for <15 minutes.
- OA most commonly affects the hips, knees, and hands (PIP and DIP joints).
- If used, intra-articular steroid injections should be limited to no more than 2 per joint per year.
- PRP and/or BMAC are (higher-cost) options for early-stage knee OA.
- In the US, intra-articular HA is classified as a medical device (rather than a drug).
- Base long-term therapy on patient pain management and activity goals.
OSTEOMYELITIS
Matthew Mandell, DO ● Adam N. Treitman, MD

BASICS

DESCRIPTION

- An acute or chronic bone infection with associated inflammation; can occur as a result of hematogenous seeding, contiguous spread of infection, or direct inoculation into intact bone (trauma or surgery)
- Two major classification systems:
  - Lew and Waldvogel
    - Classified according to duration (acute or chronic) and mechanism of infection (hematogenous, contiguous)
  - Cierny-Mader classification
    - Based on the portion of bone affected, physiologic status of the host, and risk factors
- Special situations
  - Vertebral osteomyelitis
    - Also results from hematogenous seeding (most common), direct inoculation, or contiguous spread
    - Back pain is most common initial symptom.
    - Lumbar spine is most commonly involved, followed by thoracic spine.
    - Neurologic symptoms in 1/3 of patients (1)[C]
    - Surgery is required if neurologic symptoms or infected spinal implant. Uncomplicated acute hematogenous vertebral osteomyelitis can be treated with 6 weeks of antibiotics alone (1)[C].
  - Infections of prosthetic joints
    - X-ray and three-phase bone scan. MRI/CT is of limited use with prostheses.
    - Treat with pathogen-directed antibiotic therapy; may include rifampin (4 to 6 weeks) for higher success rate—penetrates biofilm
  - Posttraumatic infections depend on type and severity of fracture; level of contamination
    - Tibia is the most commonly involved.

EPIDEMIOLOGY

- Predominant age: more common in older adults
- Predominant sex: male > female
- Hematogenous osteomyelitis
  - Adults (most >50 years of age): vertebral
  - Children: long bones
- Contiguous osteomyelitis: related to diabetic foot infections (DFIs), decubitus ulcers, and infected total joint arthroplasties in older adults; trauma and surgery in younger adults
- Mycobacterium tuberculosis (MTB) is the most common cause of vertebral osteomyelitis worldwide. It is more likely to involve multiple vertebral bodies—especially of the thoracic spine—and is associated with paraspinal abscess formation.

Incidence
Generally low; normal bone is resistant to infection.

**Prevalence**
Up to 66% of diabetics with foot ulcerations

**ETIOLOGY AND PATHOPHYSIOLOGY**

- **Acute**: suppurative infection of bone with edema and vascular compromise leading to sequestrum (segments of necrotic bone, may contain pus)
- **Chronic**: presence of necrotic bone or sequestrum or recurrence of previous infection
- **Hematogenous osteomyelitis** (typically monomicrobial)
  - Staphylococcus aureus (most common)
  - Coagulase-negative staphylococci and aerobic gram-negative bacteria
  - Salmonella sp. (sickle cell disease)
  - MTB and fungi (rare) in endemic areas or in immunocompromised hosts
- **Contiguous focus osteomyelitis** (polymicrobial)
  - Diabetes or vascular insufficiency
    - Coagulase-positive and coagulase-negative staphylococci
    - Streptococci, gram-negative bacilli, anaerobes (Peptostreptococcus sp.)
  - Sacral decubitus ulcer
    - Pressure-related skin ulceration and necrosis
    - May require débridement to healthy bone and/or soft tissue coverage/surgical flap procedure (2)[C]
  - Nail puncture through a shoe
    - P. aeruginosa
- **Prosthetic device**
  - Coagulase-negative staph and S. aureus

**RISK FACTORS**

- Diabetes mellitus (particularly, diabetic foot ulcer)
- Recent trauma/surgery
- Foreign body (e.g., prosthetic implant)
- Neuropathy and vascular insufficiency
- Immunosuppression
- Sickle cell disease
- Injection drug use
- Previous osteomyelitis
- Bacteremia

**GENERAL PREVENTION**

- Comprehensive annual foot exam for diabetic patients
- Screen for peripheral artery disease.
- Optimize glycemic control in diabetes.
- Antibiotic prophylaxis for posttraumatic infection
  - Clean bone surgery.
    - Administer IV antibiotics within an hour of skin incision; continue ≤24 hours postprocedure.
  - Closed fractures
- Cefazolin, cefuroxime, clindamycin (β-lactam allergy), or vancomycin (β-lactam allergy or MRSA infection)
  - Open fractures
- In patients who can receive antibiotics within 3 hours of injury with prompt operative treatment, 1st-generation cephalosporins are preferred (clindamycin or vancomycin if allergic). Ceftriaxone for type III fractures. Add metronidazole if associated with soil or fecal matter contamination.

### DIAGNOSIS

#### HISTORY
- Fever, chills, pain, swelling, and erythema, particularly in acute osteomyelitis. These features may be absent in chronic osteomyelitis.
- Hematogenous osteomyelitis
  - Elicit a history of conditions predisposing to bacteremia (diabetes, hemodialysis, invasive procedures, IV drug use, immunosuppression).
- Contiguous osteomyelitis and vascular insufficiency
  - Recent trauma/surgery within 1 to 2 months
  - Presence of prosthetic device
  - History of diabetes/DFI
- Chronic osteomyelitis
  - History of acute osteomyelitis
  - Draining sinus tract

#### PHYSICAL EXAM
- Fever, restricted range of motion, tenderness, signs of localized inflammation
- Motor and sensory deficits (vertebral infection)
- Probe to bone test in DFI has high pooled sensitivity and specificity for osteomyelitis of 0.87 (95% CI 0.75–0.93) and 0.83 (95% CI 0.65–0.93), respectively (3)[A].
- Exposed bone in the setting of DFI (4)[A]
- Ulcer >2-cm wide and >2-cm deep increases likelihood for osteomyelitis in DFI (positive LR, 7.2; 95% CI 1.1–49; negative LR, 0.48; 95% CI 0.31–0.76) (5)[A].
- Positive probe to bone test and ulcer area >2 cm² are physical exam findings that best support osteomyelitis in the setting of DFI (5)[A].
- Classic signs and symptoms of infection may be masked in diabetics due to vascular disease and neuropathy.

#### DIFFERENTIAL DIAGNOSIS
- Systemic infection from other source
- Aseptic bone infarction
- Localized inflammation or infection of overlying skin and soft tissues (e.g., gout)
- Brodie abscess (subacute osteomyelitis)
- Neuropathic joint disease (Charcot foot)
- Fractures/trauma
- Tumor
**DIAGNOSTIC TESTS & INTERPRETATION**

### Initial Tests (lab, imaging)

<table>
<thead>
<tr>
<th>Labs</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>- WBC is not reliable (can be normal) (1)[A],(5)[C].</td>
<td></td>
</tr>
<tr>
<td>- CRP is usually elevated (nonspecific).</td>
<td></td>
</tr>
<tr>
<td>- ESR is high in most cases:</td>
<td></td>
</tr>
<tr>
<td>- ESR &gt;70 mm/hr increases likelihood (LR, 11; 95% CI 1.6–79) (5)[A].</td>
<td></td>
</tr>
<tr>
<td>- Procalcitonin may also be elevated.</td>
<td></td>
</tr>
<tr>
<td>- Antibiotics given prior to culture may alter results.</td>
<td></td>
</tr>
<tr>
<td>- Other disorders that may alter lab results: immunosuppression (including diabetes), chronic inflammatory disease, other sites of infection</td>
<td></td>
</tr>
<tr>
<td>- Routine radiography is first-line imaging: Classic triad for osteomyelitis is demineralization, periosteal reaction, and bone destruction:</td>
<td></td>
</tr>
<tr>
<td>- Bone destruction is not apparent on plain films until after 10 to 21 days of infection.</td>
<td></td>
</tr>
<tr>
<td>- Bone scan is first test after plain x-ray for evaluation of prosthesis-related infection.</td>
<td></td>
</tr>
<tr>
<td>- Radionuclide scanning (e.g., technetium, indium, or gallium) helps if diagnosis is ambiguous or unsure of extent of disease; limited by low sensitivity/specificity</td>
<td></td>
</tr>
<tr>
<td>- MRI</td>
<td></td>
</tr>
<tr>
<td>- Best for visualization of septic arthritis, spinal infection, and DFI (1)[C],(4)[A]</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>- T2-weighted image: high signal intensity</td>
<td></td>
</tr>
<tr>
<td>- MRI: sensitivity 90% and specificity 83% for osteomyelitis in diabetic foot ulcers (5)[A]</td>
<td></td>
</tr>
<tr>
<td>- For diabetic foot ulcer, a positive MRI increases the likelihood of osteomyelitis (positive LR, 3.8; 95% CI 2.5–5.8) (5)[A].</td>
<td></td>
</tr>
<tr>
<td>- A normal MRI makes osteomyelitis less likely (negative LR, 0.14; 95% CI 0.08–0.20) (5)[A].</td>
<td></td>
</tr>
<tr>
<td>- MRI does not help assess the response to therapy due to persistence of bony edema.</td>
<td></td>
</tr>
<tr>
<td>- CT</td>
<td></td>
</tr>
<tr>
<td>- Better than standard radiography to evaluate bony fragments and sequestration; inferior to MRI for soft tissue and bone marrow assessment</td>
<td></td>
</tr>
</tbody>
</table>

### Follow-Up Tests & Special Considerations

- A persistently elevated CRP (4 to 6 weeks) can be associated with osteomyelitis but is nonspecific.
- Monitor patients receiving prolonged antimicrobial therapy with weekly labs.

### Diagnostic Procedures/Other

- Blood cultures and bone biopsy
  - For vertebral/hematogenous osteomyelitis, definitive diagnosis is made by vertebral disc aspiration or blood culture.
  - Patients with positive blood cultures (with a pathogen likely to cause vertebral/hematogenous osteomyelitis) and with radiographic evidence of osteomyelitis do not need bone biopsy.
  - For contiguous osteomyelitis, definitive diagnosis is made by bone biopsy for culture and histology.
  - Avoid wound swabs or needle aspiration in DFI and decubitus ulcers because these do not correlate well with bone biopsy culture (2)[A],(4)[C].
  - Can obtain bone biopsy at same time as surgical débridement
Test Interpretation
Pathology of bone revealing inflammatory process with pyogenic bacteria and necrosis

**TREATMENT**

**GENERAL MEASURES**
Adequate nutrition, smoking cessation, glycemic control

**MEDICATION**
- In clinically stable patients, delay initiation of empiric antibiotics until biopsy and/or blood cultures have been obtained.
- Direct empiric therapy toward probable organism and tailor according to culture results.
- Optimal antimicrobial concentration at infected site is essential (consider vascular perfusion).
- Adjust antibiotic dosing according to renal function.
- 4 to 6 weeks of therapy is appropriate for most cases of acute osteomyelitis. In the setting of amputation or complete removal of infected bone, a 2-week course of pathogen-directed antibiotics may be adequate (2)[C].
- If a prosthetic joint or other orthopedic hardware cannot be removed or completely débrided, a prolonged 6-week course of parenteral antibiotics is indicated. Some patients may subsequently require long-term oral antimicrobial suppression.
- Consider longer treatment courses for chronic osteomyelitis or MRSA infection (minimum 8 weeks).
- Empiric therapy:
  - For vertebral/hematogenous osteomyelitis, include coverage for MRSA and gram-negative organisms.
  - IV vancomycin plus 3rd- or 4th-generation IV cephalosporin +/- metronidazole for DFI/contiguous osteomyelitis

**First Line**
- S. aureus or coagulase-negative staphylococci
  - MSSA: β-lactam at high dose (nafcillin or oxacillin 2 g IV q4h) or cefazolin 1 to 2 g IV q8h (use 2 g for patients >80 kg)
  - MRSA: vancomycin 15 to 20 mg/kg IV q8–12h (use q8h interval if CrCl >70 mL/min) with target trough of 15 to 20 μg/mL, not to exceed 2 g/dose
- Streptococcus sp.
  - Ceftriaxone 2 g IV q24h or cefazolin 2 g IV q8h
- Enterobacter sp.
  - Ciprofloxacin 750 mg PO q12h (or 400 mg IV q12h) or cefepime 2 g IV q12h
- P. aeruginosa
  - Cefepime 2 g IV q8h or ciprofloxacin 750 mg PO q12h (or 400 mg IV q8h)

**Second Line**
- S. aureus
  - MSSA: ceftriaxone 2 g IV q24h
  - MRSA: linezolid 600 mg PO/IV q12h or daptomycin 6 mg/kg IV q24h
- Streptococcus sp.
- Penicillin G 4 million U q4–6h
- Enterobacter sp. (quinolone-resistant, including extended-spectrum β-lactamase–producing Escherichia coli)
  - Carbapenem (imipenem/cilastatin) 500 mg IV q6h
- P. aeruginosa
  - Piperacillin-tazobactam 3.375 q IV q6h

**ALERT**
The combination of vancomycin plus piperacillin-tazobactam can increase risk of acute kidney injury (number needed to harm 11) (6)[A].

**ADDITIONAL THERAPIES**
Evidence does not support the use of hyperbaric oxygen therapy, growth factors, maggots, or topical negative pressure for diabetic foot osteomyelitis (4)[A].

**SURGERY/OTHER PROCEDURES**
- Surgical drainage, minimizing dead space, adequate soft tissue coverage, restoration of blood supply, and removal of necrotic tissues improve cure rates.
- Débridement of necrotic bone was once thought to be the cornerstone to management; however, recent evidence suggests antibiotics alone may be sufficient for DFI (4)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Off-load pressure
- Discharge criteria: clinical and laboratory evidence of resolving infection and appropriate outpatient therapy

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Blood levels of antimicrobial agents, ESR, CRP, and repeat plain radiography as clinical course dictates. CRP correlates more closely with clinical response to therapy than ESR.

**PATIENT EDUCATION**
Diabetic glycemic control and foot care

**PROGNOSIS**
- Superficial and medullary osteomyelitis treated with antimicrobial and surgical therapy have a response rate of 90–100%.
- Up to 36% recurrence rate in diabetics
- Increased mortality after amputation

**COMPLICATIONS**
- Abscess formation
- Bacteremia
- Fracture/nonunion
- Loosening of prosthetic implant
Postoperative infection
Sinus tract formation can be associated with neoplasms, especially in presence of long-standing infection.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- M86.9 Osteomyelitis, unspecified
- M86.00 Acute hematogenous osteomyelitis, unspecified site
- M86.10 Other acute osteomyelitis, unspecified site

CLINICAL PEARLS
- Hematogenous osteomyelitis is usually monomicrobial. Osteomyelitis due to contiguous spread or direct inoculation is usually polymicrobial.
- Pain associated with acute osteomyelitis typically is gradual in onset.
- Treatment of chronic osteomyelitis often requires both surgical débridement and at least 6 weeks of antimicrobial therapy.
- Unlike diabetic foot ulcers, a positive probe-to-bone test (or frankly exposed bone) and abnormal MRI findings are not diagnostic of osteomyelitis in stage IV sacral pressure ulcers.
- Definitive treatment of osteomyelitis in stage IV sacral pressure ulcers often requires surgical débridement to healthy bone.
- Follow-up MRI is not needed for patients who are clinically improving with appropriate treatment.
- In diabetic foot wounds, if there are no signs or symptoms of soft tissue or bone infection, antibiotic therapy is unnecessary.
OSTEOPOROSIS AND OSTEOPENIA
Caitlin A. Nicholson, MD ● Rahul Kapur, MD, CAQSM

BASICS

DESCRIPTION
A skeletal disease characterized by low bone mass, deterioration of bone tissue, and disruption of bone architecture that leads to compromised bone strength and an increased risk of fracture.

EPIDEMIOLOGY
- Most common bone disease in humans
- Predominant age: elderly >60 years of age
- Predominant sex: female > male (80%/20%)

Incidence
There are poor data on the incidence of osteoporosis and osteopenia; however, there are an estimated 9 million fractures annually attributed to osteoporosis worldwide.

Prevalence
- >10.2 million Americans have osteoporosis
- >43.4 million Americans have osteopenia
- Women >50 years of age: osteoporosis 15.4% and osteopenia 51.4%
- Men >50 years of age: osteoporosis 4.3% and osteopenia 35.2%
- One in three women and one in five men will experience an osteoporotic fracture in their lifetime

ETIOLOGY AND PATHOPHYSIOLOGY
- Imbalance between bone resorption and bone formation
- Aging
- Hypoestrogenemia

Genetics
- Familial predisposition
- More common in Caucasians and Asians than in African Americans and Hispanics

RISK FACTORS
- Nonmodifiable:
  - Age >65 years
  - Female gender and menopause
  - Caucasian or Asian race
  - Family history of osteoporosis
  - History of atraumatic fracture
- Modifiable:
  - Low body weight (<58 kg or body mass index [BMI] <21)
  - Calcium/vitamin D deficiency
  - Inadequate physical activity
  - Cigarette smoking
– Excessive alcohol intake (>3 drinks per day)
– Medications: See “Commonly Associated Conditions”

GENERAL PREVENTION
The aim in the prevention and treatment of osteoporosis is to prevent fracture:
- Regularly perform weight-bearing exercise
- Consume a diet that includes adequate calcium (1,000 mg/day for men ages 50 to 70 years and 1,200 mg/day for women ages 51+ years and men 70+ years) and vitamin D (800 to 1,000 IU/day).
- Evidence is insufficient to recommend daily supplementation with >1,000 mg of calcium and >400 IU of vitamin D₃ for the primary prevention of fractures in community-dwelling postmenopausal women. The U.S. Preventive Services Task Force (USPSTF) recommends against daily supplementation with ≤1,000 mg calcium and ≤400 IU vitamin D₃ for the primary prevention of fractures in this group (1)[B].
- Avoid smoking
- Limit alcohol consumption (<3 drinks per day)
- Fall prevention (home safety assessment, correction of visual impairment)
- Screen (USPSTF recommendations):
  – All women ≥65 years of age (1)[B]
  – Women >50 years of age with a 10-year risk of major osteoporotic fracture (using the World Health Organization’s [WHO] Fracture Risk Assessment [FRAX] Tool) >8.4% (2)
  – The current evidence is insufficient to recommend screening for osteoporosis in men; however, the National Osteoporosis Foundation recommends screening men age >70 years, especially if at increased risk.
  – Limited evidence from good-quality studies found no benefit in predicting fractures from repeating bone mineral density (BMD) testing 4–8 years after initial screening (2).

COMMONLY ASSOCIATED CONDITIONS
- Malabsorption syndromes: gastrectomy, inflammatory bowel disease, celiac disease
- Hypoestrogenism: menopause, hypogonadism, eating disorders, functional hypothalamic amenorrhea
- Endocrinopathies: hyperparathyroidism, hyperthyroidism, hypercortisolism, diabetes mellitus
- Hematologic disorders: hemophilia, sickle cell disease, multiple myeloma, thalassemia, hemochromatosis
- Other chronic diseases: multiple sclerosis, end-stage renal disease, rheumatoid arthritis, lupus, chronic obstructive pulmonary disease (COPD), HIV/AIDS
- Medications: antiepileptics, aromatase inhibitors (raloxifene), chronic corticosteroids (>5 mg prednisone or equivalent for >3 months), medroxyprogesterone acetate, heparin, SSRIs, thyroid hormone (in supraphysiologic doses), PPIs

DIAGNOSIS
HISTORY
- Review modifiable and nonmodifiable risk factors
- Online FRAX tool: http://www.shef.ac.uk/FRAX/
- Assess for commonly associated conditions.
PHYSICAL EXAM
- Thoracic kyphosis, poor balance, deconditioning
- Historical height loss >4 cm (difference between current height and peak height at age 20 years)
- Prospective height loss >2 cm (difference between current height and previously documented height)

DIFFERENTIAL DIAGNOSIS
- Multiple myeloma/other neoplasms
- Osteomalacia
- Type I collagen mutations
- Osteogenesis imperfecta

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Dual energy x-ray absorptiometry (DEXA) of the lumbar spine/hip is considered the gold standard for measuring BMD and for diagnosing osteoporosis
  - A BMD at the hip or lumbar spine that is ≤2.5 standard deviations below the mean BMD of a young-adult reference population is diagnostic of osteoporosis.
  - A minimum of 2 years may be needed to reliably measure a change in BMD.
  - BMD is expressed in terms of T-scores and Z-scores:
    - T-score is the number of standard deviations a patient’s BMD deviates from the mean of young (25 to 40 years old) control individuals of the same sex.
    - The WHO defines normal BMD as a T-score ≥−1; osteopenia as a T-score between −1 and −2.5; and osteoporosis as a T-score ≤−2.5.
    - WHO thresholds can be used for postmenopausal women and men >50 years of age
    - Z-score is a comparison of the patient’s BMD with an age-matched population.
    - A Z-score <−2 should prompt evaluation for causes of secondary osteoporosis.
- Consider screening for causes of secondary osteoporosis:
  - Serum 25-hydroxyvitamin D and parathyroid hormone
  - Complete blood count
  - Serum chemistries including calcium, phosphorus, magnesium, total protein, albumin, liver enzymes, creatinine, alkaline phosphatase, and TSH
  - Urinalysis (24-hour collection) for calcium, sodium, and creatinine to identify calcium malabsorption or hypercalciuria
- Plain radiographs lack sensitivity to diagnose osteoporosis, but an abnormality (e.g., widened intervertebral spaces, rib fractures, vertebral compression fractures) should prompt evaluation.

Follow-Up Tests & Special Considerations
Consider further lab work based on initial evaluation, Z-score (≤−2.5) or lower, or young age:
- Iron and ferritin (hemochromatosis)
- Testosterone levels (hypogonadism in men)
- Serum protein electrophoresis and free κ and λ light chains (multiple myeloma)
- Urinary free cortisol (Cushing disease)
- Tissue transglutaminase antibodies (celiac disease)

Diagnostic Procedures/Other
Bone biopsy may be recommended for patients with bone disease and renal failure to establish the correct diagnosis because it can assess the degree of mineralization and microarchitecture and specific bone loss mechanisms.

**Test Interpretation**
- In osteoporosis, can see reduced skeletal mass; trabecular bone thinned or lost more than cortical bone
- Can assess osteoclast and osteoblast relative activity
- Can rule out other metabolic bone diseases
- Can assess if bone marrow is normal or atrophic

**TREATMENT**
- Criteria for patients who benefit from treatment for their osteoporosis include:
  - All patients with a T-score ≤−2.5 with no risk factors
  - All postmenopausal women and men >50 years old who have had an osteoporotic vertebral/hip fracture
  - All postmenopausal women who have BMD values consistent with osteoporosis (T-score ≤2.5) at the lumbar spine, femoral neck, or total hip region
  - Postmenopausal women and men >50 years old with T-scores from −1.0 to −2.5 and a 10-year risk of an osteoporotic fracture (spine, hip, shoulder, and wrist) of at least 20% or risk of hip fracture of at least 3%, based on FRAX calculator
  - All men >50 years of age who present with a hip or vertebral fracture or a T-score ≤−2.5 after appropriate evaluation; however, evidence for the effectiveness of treatment of osteoporosis in men is limited.
- For osteopenia, treatment should focus on risk modification: weight-bearing exercise, vitamin D supplementation (2,000 to 4,000 IU/day), limiting alcohol, and smoking cessation.

**MEDICATION**

*Vitamin D 2,000 to 4,000 IU/day for all patients with osteoporosis*

**First Line**

**Bisphosphonates:**
- Mechanism: inhibition of bone resorption by osteoclasts in skeletal tissue, reducing the incidence of vertebral and nonvertebral fractures
  - Alendronate 10 mg PO daily or 70 mg PO weekly
  - Risedronate 5 mg PO daily, 35 mg PO weekly, or 150 mg PO monthly
  - Zoledronic acid 5 mg IV yearly
- Zoledronic acid appears to be the most effective in preventing vertebral and nonvertebral fractures (3)[A].
- Side effects are similar for all bisphosphonates and include gastrointestinal problems such as difficulty swallowing and inflammation of the esophagus and stomach
- Osteonecrosis of the jaw is a risk, particularly in patients with cancer who receive high doses and those who receive IV treatment (4).
- There is a possible risk of midfemur fractures in patients receiving bisphosphonates for >5 years (3).
- Avoid oral bisphosphonates in patients with:
– Delayed esophageal emptying
– Inability to stand/sit upright for at least 30 to 60 minutes after taking the bisphosphonates
– Hypocalcemia (Correct prior to initiating therapy)
– Severe renal impairment (creatinine clearance \([\text{CrCl}] \leq 30\) for risedronate and \(\leq 35\) mL/min for alendronate and zoledronic acid)

**Second Line**
- Denosumab: 60 mg SQ every 6 months
  - Human monoclonal antibody receptor activator of nuclear factor kappa-B ligand (RANKL) receptor
  - Inhibits osteoclast formation
- Teriparatide 20 mg SQ daily
  - Recombinant formulation of PTH
  - Works anabolically to stimulate the growth of bone through osteoblastic activation
  - Studies have shown a reduction in the incidence of vertebral fractures by 65% and nonvertebral fractures by 53%
  - No data exist on its safety and efficacy after >2 years of use
- Estrogen 0.625 mg PO daily (with progesterone if patient has a uterus): effective in prevention and treatment of osteoporosis (34% reduction in hip and vertebral fractures after 5 years of use), but the risks (e.g., increased rates of myocardial infarction, stroke, breast cancer, pulmonary embolus, and deep vein thrombosis) must be weighed against the benefits
- Raloxifene 60 mg PO daily is a selective estrogen receptor modulator with positive effects on BMD and vertebral fracture risk but no stimulatory actions on breasts/uterus. It can be considered in the treatment and prevention of osteoporosis in postmenopausal women with high risk for invasive breast cancer; however, this must be weighed against the risks of DVT, PE, or stroke (especially in postmenopausal women at risk for coronary heart disease) (3)
- Strontium 2 g PO daily
  - Appears to inhibit bone resorption and increase bone formation
  - Available for use in Europe
- Calcitonin
  - PTH antagonist that reduces osteoclastic activity, therefore decreasing bone turnover
  - FDA-approved for treatment of osteoporosis in women who are at least 5 years postmenopausal when alternative treatments are not suitable
  - Reduces vertebral fracture occurrence in those with prior vertebral fracture
  - Associated with an increased risk for malignancy

**ISSUES FOR REFERRAL**
Endocrinology for recurrent bone loss/fracture

**ADDITIONAL THERAPIES**
- Weight-bearing exercise 30 minutes 3 times per week
- Counseling on fall prevention
- Smoking cessation
- Physical therapy to help with muscle strengthening

**SURGERY/OTHER PROCEDURES**
Options for patients with painful vertebral compression fractures failing medical treatment:
- Vertebroplasty: Orthopedic cement is injected into the compressed vertebral body
Kyphoplasty: A balloon is expanded within the compressed vertebral body to reconstruct volume of vertebrae. Cement is injected into the space.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Isoflavones not better than placebo for fracture risk
- Beneficial effect of Chinese herbal medicines in improving BMD is still uncertain

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient care for pain control of acute back pain secondary to new vertebral fractures and for acute treatment of femoral and pelvic fractures
- Rehabilitation, nursing home, or home care may be needed following hospitalization for fractures

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Weight-bearing exercises such as walking, jogging, stair climbing, and tai chi have been shown to decrease falls and fracture risk.
- Yearly height measurement is essential to determination of osteoporosis treatment efficacy. Patients who lose >2 cm in height should have repeat vertebral imaging to determine if any new vertebral fractures have occurred (5).
- Although there is no consensus, most recommendations suggest repeating a DEXA scan to assess BMD 2 years after starting bisphosphonate therapy
- A comprehensive risk assessment should be performed after 3 to 5 years of treatment. If BMD at the hip is >−2.5 (T-score) and the patient has not had a hip or vertebral fracture, consider discontinuing treatment. If BMD remains low or if the patient is at high risk for fractures, the patient may benefit by continuing treatment beyond 5 years (6).
- Physicians prescribing bisphosphonates should advise patients of the small risk of osteonecrosis of the jaw and encourage dental examinations (6).

DIET
- Diet to maintain normal body weight
- Calcium and vitamin D (see “General Prevention”)

PATIENT EDUCATION
National Osteoporosis Foundation: http://nof.org/

PROGNOSIS
- With treatment, 80% of patients stabilize skeletal manifestations, increase bone mass and mobility, and have reduced pain.
- 15% of vertebral and 20–40% of hip fractures may lead to chronic care and/or premature death.

COMPLICATIONS
Severe, disabling pain and recurrent fractures
REFERENCES

CODES

ICD10
- M85.80 Other specified disorders of bone density and structure, unspecified site
- M81.0 Age-related osteoporosis w/o current pathological fracture
- M80.00XA Age-rel osteopor w current path fracture, unsp site, in it

CLINICAL PEARLS

- Regular weight-bearing exercise from adolescence onward is recommended for prevention.
- Screen all women ≥65 years of age with DEXA scans.
- Premenopausal women with osteoporosis should be screened for secondary causes such as malabsorption syndromes, hyperparathyroidism, hyperthyroidism, and medication sensitivity.
- Evaluate and treat all patients presenting with fractures from minimal trauma.
- Bisphosphonates are first line for treatment of osteoporosis in most patients.
- For osteopenia, treat with counseling on fall prevention, weight-bearing exercise, diet high in calcium and vitamin D, limiting alcohol, and smoking cessation.
- If the patient is not responding to treatment, consider screening for a secondary, treatable cause of osteoporosis.
OTITIS EXTERNA
Douglas S. Parks, MD

BASICS

DESCRIPTION
Inflammation of the external auditory canal:

- Acute diffuse otitis externa: the most common form; an infectious process; usually bacterial; occasionally fungal (10%)
- Acute circumscribed otitis externa: synonymous with furuncle; associated with infection of the hair follicle, a superficial cellulitic form of otitis externa
- Chronic otitis externa: same as acute diffuse but of longer duration (>6 weeks)
- Eczematous otitis externa: may accompany typical atopic eczema or other primary skin conditions
- Necrotizing malignant otitis externa: an infection that extends into the deeper tissues adjacent to the canal; may include osteomyelitis and cellulitis; rare in children

System(s) affected: skin/exocrine
Synonym(s): swimmer’s ear

EPIDEMIOLOGY

Incidence
- Unknown; higher in the summer months and in warm, wet climates
- Predominant age: all ages
- Predominant sex: male = female

Prevalence
- Acute, chronic, and eczematous: common
- Necrotizing: uncommon

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute diffuse otitis externa
  - Traumatized external canal (e.g., from use of cotton swab)
  - Bacterial infection (90%): Pseudomonas (67%), Staphylococcus, Streptococcus, gram-negative rods
  - Fungal infection (10%): Aspergillus (90%), Candida, Phycomycetes, Rhizopus, Actinomycetes, Penicillium

- Chronic otitis externa: bacterial infection: Pseudomonas

- Eczematous otitis externa (associated with primary skin disorder)
  - Eczema
  - Seborrhea
  - Psoriasis
  - Neurodermatitis
  - Contact dermatitis
  - Purulent otitis media
  - Sensitivity to topical medications

- Necrotizing otitis externa
– Invasive bacterial infection: Pseudomonas, increasing incidence of methicillin-resistant
  Staphylococcus aureus (MRSA)
  – Associated with immunosuppression

**RISK FACTORS**

- Acute and chronic otitis externa
  - Traumatization of external canal
  - Swimming
  - Hot, humid weather
  - Hearing aid use
- Eczematous: primary skin disorder
- Necrotizing otitis externa in adults
  - Advanced age
  - Diabetes mellitus (DM)
  - Debilitating disease
  - AIDS
  - Immunosuppression
- Necrotizing otitis externa in children (rare)
  - Leukopenia
  - Malnutrition
  - DM
  - Diabetes insipidus

**GENERAL PREVENTION**

- Avoid prolonged exposure to moisture.
- Use preventive antiseptics (acidifying solutions with 2% acetic acid [white vinegar] diluted
  50/50 with water or isopropyl alcohol or 2% acetic acid with aluminum acetate [less
  irritating]) after swimming and bathing.
- Treat predisposing skin conditions.
- Eliminate self-inflicted trauma to canal with cotton swabs and other foreign objects.
- Diagnose and treat underlying systemic conditions.
- Use ear plugs when swimming.

**DIAGNOSIS**

**HISTORY**
Variable length history of itching, plugging of ear, ear pain, and discharge from ear

**PHYSICAL EXAM**
- Ear canal: red, containing purulent discharge and debris
- Pain on manipulation of the pinnae
- Possible periauricular adenitis
- Possible eczema of pinna
- Cranial nerve (VII, IX to XII) involvement (extremely rare)

**DIFFERENTIAL DIAGNOSIS**
- Idiopathic ear pain
- Otitis media with perforation
- Hearing loss
- Cranial nerve (VII, IX to XII) palsy with necrotizing otitis externa
- Wisdom tooth eruption
- Basal cell or squamous cell carcinoma

**DIAGNOSTIC TESTS & INTERPRETATION**
- Gram stain and culture of canal discharge (occasionally helpful)
- Antibiotic pretreatment may affect results.
- Radiologic evaluation of deep tissues in necrotizing otitis externa with high-resolution CT scan, MRI, gallium scan, and bone scan

**Test Interpretation**
- Acute and chronic otitis externa: desquamation of superficial epithelium of external canal with infection
- Eczematous otitis externa: pathologic findings consistent with primary skin disorder; secondary infection on occasion
- Necrotizing otitis externa: vasculitis, thrombosis, and necrosis of involved tissues; osteomyelitis

**TREATMENT**
Outpatient treatment, except for resistant cases and necrotizing otitis externa

**GENERAL MEASURES**
- Cleaning the external canal may facilitate recovery.
- Analgesics as appropriate for pain
- Antipruritic and antihistamines (eczematous form)
- Ear wick (Pope) for nearly occluded ear canal

**MEDICATION**
- Trial data is of generally poor quality and may not be fully relevant to primary care settings (1)[A].
- Resistance is an increasing problem. Pseudomonas is the most common bacteria, and it is more susceptible to fluoroquinolones such as ciprofloxacin or ofloxacin, with increasing resistance to aminoglycocide. Staphylococcus is equally susceptible to both fluoroquinolones and polymyxin B combinations (2)[A]. If a patient has recurring episodes or is not improved in 2 weeks, change the class of antibacterial and consider cultures and sensitivities.
- There is evidence that use of a topical antibiotic with a corticosteroid shortens time to symptom resolution, although there is no evidence that it increases overall cure rate. There is not enough evidence to demonstrate that any antibiotic regimen is clearly superior to any other (3)[B],(4)[A].
- Oral antibiotics are indicated only if there is associated otitis media. Oral antibiotics alone are not effective and markedly increase the risk of progressing to chronic otitis externa.
- Analgesics as needed; narcotics may be necessary. Recurrent otitis externa may be prevented by applying equal parts white vinegar and isopropyl alcohol (over-the-counter [OTC] rubbing alcohol) to external auditory canals after bathing and swimming.
**First Line**

- **Acute bacterial and chronic otitis externa**
  - Ciprofloxacin 0.3% and dexamethasone 0.1% suspension (expensive as brand): 4 drops BID for 7 days or ofloxacin 0.3% solution (inexpensive generic): 10 drops once a day for 7 days (1)[A]; less ototoxicity and reported antibiotic resistance (5)[A]
  - Neomycin/polymyxin B/hydrocortisone (Cortisporin, generics): 5 drops QID. If the tympanic membrane is ruptured, use the suspension; otherwise, the solution may be used; may be ototoxic and resistance-developing in *Staphylococcus* and *Streptococcus* sp.; not expensive
  - Acetic acid 2% with hydrocortisone 1%: 3 to 5 drops q4–6h for 7 days; may cause minor local stinging. An inexpensive generic. This is as effective as neomycin–polymyxin B. It may take up to 2 days longer to achieve resolution of symptoms (3)[A]. A wick may be helpful in severe cases by keeping the canal open and keeping antibiotic solution in contact with infected skin.

- **Fungal otitis externa**
  - Topical therapy, antiyeast for *Candida* or yeast: 2% acetic acid, 3 to 4 drops QID; clotrimazole 1% solution; itraconazole oral
  - Parenteral antifungal therapy: amphotericin B
  - Patients with Ramsay Hunt syndrome: acyclovir IV

- **Eczematous otitis externa: topical therapy**
  - Acetic acid 2% in aluminum acetate
  - Aluminum acetate (5%; Burow solution)
  - Steroid cream, lotion, ointment (e.g., triamcinolone 0.1% solution)
  - Antibacterial, if superinfected

- **Necrotizing otitis externa**
  - Parenteral antibiotics: antistaphylococcal and antipseudomonal
  - 4 to 6 weeks of therapy
  - Fluoroquinolones PO for 2 to 4 weeks

**Second Line**

- **Acute bacterial and chronic otitis externa**
  - Betamethasone 0.05% solution may be as effective as a polymyxin B combination without the risk of ototoxicity or antibiotic resistance. However, the data are not very robust, and more study is needed (3)[A].

- **Azole antifungals for fungal otitis externa**

**ISSUES FOR REFERRAL**

Resistant cases or those requiring surgical intervention

**SURGERY/OTHER PROCEDURES**

For necrotizing otitis externa or furuncle

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- OTC white vinegar; 3 drops in affected ear for minor case
- Tea tree oil in various concentrations has been used as an antiseptic. Ototoxicity has been reported in animal studies at very high doses.
- Grapefruit seed extract in various concentrations has been described as useful in the lay literature.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: necrotizing otitis media requiring parenteral antipseudomonal antibiotics
- Discharge criteria: resolution of infection

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
No restrictions

Patient Monitoring
- Acute otitis externa
  - 48 hours after therapy instituted to assess improvement
  - At the end of treatment
- Chronic otitis externa
  - Every 2 to 3 weeks for repeated cleansing of canal
  - May require alterations in topical medication, including antibiotics and steroids
- Necrotizing otitis externa
  - Daily monitoring in hospital for extension of infection
  - Baseline auditory and vestibular testing at beginning and end of therapy

DIET
No restrictions

PROGNOSIS
- Acute otitis externa: rapid response to therapy with total resolution
- Chronic otitis externa: With repeated cleansing and antibiotic therapy, most cases will resolve. Occasionally, surgical intervention is required for resistant cases.
- Eczematous otitis externa: Resolution will occur with control of the primary skin condition.
- Necrotizing otitis externa: usually can be managed with débridement and antipseudomonal antibiotics; recurrence rate is 100% when treatment is inadequate. Surgical intervention may be necessary in resistant cases or if there is cranial nerve involvement. Mortality rate is significant, probably secondary to the underlying disease (6)[C].

COMPLICATIONS
- Mainly a problem with necrotizing otitis externa; may spread to infect contiguous bone and CNS structures
- Acute otitis externa may spread to pinna, causing chondritis.

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Ear Pain/Otalgia

**CODES**

**ICD10**

- H60.523 Acute chemical otitis externa, bilateral
- H60.593 Other noninfective acute otitis externa, bilateral
- B37.84 Candidal otitis externa

**CLINICAL PEARLS**

- Acute diffuse otitis externa is the most common form: bacterial (90%), occasionally fungal (10%).
- Acute circumscribed otitis externa is associated with infection of a hair follicle.
- Chronic otitis externa is the same as acute diffuse but of longer duration (>6 weeks).
- Eczematous otitis externa may accompany typical atopic eczema or other primary skin conditions.
- Necrotizing malignant otitis externa is an infection that extends into the deeper tissues adjacent to the canal. It may include osteomyelitis and cellulitis; it is rare in children.
OTITIS MEDIA
Sahil Mullick, MD ● Andrew Slusarek, BMSc, MBBS

BASICS

DESCRIPTION
● Inflammation of the middle ear; usually accompanied by fluid collection
● Acute otitis media (AOM): inflammation of the middle ear. Rapid onset; cause may be infectious, either viral (AOM-v) or bacterial (AOM-b), but there is also a sterile etiology (AOM-s).
● Recurrent AOM: ≥3 episodes in 6 months or ≥4 episodes in 1 year with ≥1 in the past 6 months
● Otitis media with effusion (OME): fluid in the middle ear without signs or symptoms of infection
● Chronic otitis media (COM): recurrent or chronic ear infections; with or without cholesteatoma
● System(s) affected: nervous
● Synonym(s): secretory or serous otitis media, glue ear

EPIDEMIOLOGY

Incidence
● AOM
  – Predominant age: 6 to 24 months; declines >7 years; rare in adults
  – Predominant gender: male > female
  – ~80% of children have had at least 1 episode of AOM by age 3; 24% have had 3 or more episodes.
  – Placement of tympanostomy tubes is second only to circumcision as the most frequent surgical procedure in infants.
  – Increased incidence in the fall and winter
● OME
  – 90% of children have had at least one episode by age 4.

Prevalence
● Most common infection for which antibacterial agents are prescribed in the United States
● >5 million cases diagnosed per year in the United States

ETIOLOGY AND PATHOPHYSIOLOGY
● AOM-b (bacterial): Usually, a preceding viral upper respiratory infection (URI) can produce eustachian tube dysfunction, leading to reduced clearance.
  – Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis are most frequent pathogens. Streptococcus pyogenes, Mycoplasma spp are less frequent.
● AOM-v (viral): 15–44% of AOM infections are caused primarily by viruses (e.g., rhinovirus, respiratory syncytial virus, parainfluenza, influenza, enteroviruses, adenovirus, human metapneumovirus, and bocavirus).
● AOM-s (sterile/nonpathogens): 25–30%
● OME: middle ear inflammation and eustachian tube dysfunction; allergic causes are rarely substantiated.
Genetics
- Strong genetic component in twin studies for recurrent and prolonged AOM
- Immunologic defects and genetic disorders (e.g., Down syndrome) can predispose changes in physical anatomy (e.g., more horizontal and ear canals) that increase likelihood in developing otitis media.

RISK FACTORS
- Age—developing AOM prior to 1 year of age is a risk for recurrent AOM.
- Male gender
- Bottlefeeding while supine
- Routine daycare attendance
- Family history of AOM
- Frequent pacifier use after 6 months of age
- Environmental smoke exposure
- Absence of breastfeeding
- Low socioeconomic status
- Atopy
- Underlying ear/nose/throat (ENT) disease (e.g., cleft palate, allergic rhinitis)

GENERAL PREVENTION
- Pneumococcal vaccine (PCV)-7 immunization reduces the number of cases of AOM by about 29% (1)[B] (however, evidence shows that this is offset by an increase in AOM caused by other bacteria).
- Influenza vaccine (2)[B]  
- Breastfeeding for ≥6 months is protective (2)[B].
- Avoiding supine bottlefeeding, passive smoke, and pacifiers >6 months may be helpful.
- Secondary prevention: Adenoidectomy and adenotonsillectomy for recurrent AOM have limited short-term efficacy and are associated with their own adverse risks.

COMMONLY ASSOCIATED CONDITIONS
URI

DIAGNOSIS

HISTORY
- AOM:
  - Otalgia
  - Preceding or accompanying URI symptoms
  - Decreased hearing
- AOM in adults can present with only otalgia without fever, or unilateral hearing loss.
- AOM in infants and toddlers may present with only irritability in early months of life.
- OME: usually asymptomatic and may only present with decreased hearing

PHYSICAL EXAM
- AOM:
  - Fever (not required for diagnosis)
  - Decreased eardrum mobility (with pneumatic otoscopy)
– Moderate to severe bulging of tympanic membrane
– Red, yellow, or cloudy tympanic membrane
– Otorrhea

● OME:
– Eardrum often dull but not bulging
– Decreased eardrum mobility (pneumatic otoscopy)
– Presence of air-fluid level
– Weber test lateralizes to affected ear for an ear with effusion.

DIFFERENTIAL DIAGNOSIS
● Tympanosclerosis
● Trauma
● Referred pain from the jaw, teeth, or throat
● TMJ in adults
● Otitis externa
● Otitis-conjunctivitis syndrome
● Temporal arteritis in adults

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
White blood cell count may be elevated in bacterial AOM compared with sterile AOM, but this is almost never useful.

Diagnostic Procedures/Other
● Otoscopy—to document the presence of middle ear fluid
● Pneumatic otoscopy—To detect middle ear fluid (can be supplemented with tympanometry and acoustic reflex measurement). Pneumatic otoscopy is contraindicated with known tympanic perforation.
● Hearing testing is recommended when hearing loss persists for ≥3 months or at any time suspecting language delay, significant hearing loss, or learning problems.
● Language testing should be performed for children with hearing loss.
● Tympanocentesis for microbiologic diagnosis is recommended for treatment failures; may be followed by myringotomy

Test Interpretation
Pneumatic otoscopy—tympanic mobility will be impaired if middle ear fluid is present.

TREATMENT

GENERAL MEASURES
● Assess pain.
● Avoid risk factors.
● Two-thirds of children will recover without any antibiotic treatment.
● AOM: American Academy of Pediatrics/American Academy of Family Physicians (AAP/AAFP) guidelines recommend the following for observation versus antibacterial therapy for non-severe otitis media, although these guidelines are not rigorously evidence based.
  – OME/COM: Watchful waiting for 3 months per AAP/AAPP guidelines for those not at risk
(see “Complications”). Of these cases, 25–90% will recover spontaneously over this period; no benefit of antihistamines or decongestants or systemic steroids, nor significant net benefit for antibiotics (3)[B]

**MEDICATION**

**First Line**
- Significant disagreement exists about the usefulness of antibiotic treatment for this often self-resolving condition. Studies suggest number needed to treat for an additional beneficial outcome (NNTB) is 20 when looking at relief of pain at 2 to 3 days after start of antibiotics; the number needed to harm (primarily diarrhea and vomiting) is 9.
- AAP/AAFP recommends:
  - Treatment for <6 months of age: Treat with amoxicillin if >2 weeks old.
  - >6 months: Antibacterial therapy is recommended with severe otitis media (i.e., moderate to severe otalgia, otalgia >48 hours or fever ≥39°C) (3)[B] or otorrhea or bilateral otitis media between 6 months and 2 years of age.
- Observation is an option with nonsevere otitis media at >6 months of age.
- AOM: AAP/AAFP consensus guideline recommends treating with antibiotics if:
  - Between 2 weeks and 6 months, or
  - If greater then 6 months with severe otitis media (e.g., moderate to severe otalgia, otalgia >48 hours, or fevers >39°C) or
  - Otorrhea or
  - Bilateral otitis media in infants between 6 months and 2 years of age
- Treat with:
  - Amoxicillin, 80 to 90 mg/kg/day in 2 divided doses (3)[B]
- Treatment duration:
  - 10-day course for children <2 years
  - 5- to 7-day course for children ≥2 years (4)
- If penicillin allergic:
  - Cefdinir, 14 mg/kg/day in 1 to 2 doses or
  - Cefpodoxime, 10 mg/kg/day in 2 divided doses or
  - Cefuroxime 30 mg/kg/day in 2 divided doses or
  - Ceftriaxone 50 mg/kg IM/IV per day for 1 to 3 days (3)
- A single dose of azithromycin has been approved by the FDA, but studies did not include otitis-prone children or have criteria for AOM diagnosis.
- OME: See “General Measures”; no benefit to treatment. Medications promote transitory resolution in 10–15%, but the effect is short-lived (5)[B].

**Second Line**
- Alternative antibiotics are indicated for the following AOM patients:
  - Persistent symptoms after 48 to 72 hours of amoxicillin
  - AOM within 1 month of amoxicillin therapy
  - Severe earache
  - Age <6 months with high fever
  - Immunocompromised
    - Amoxicillin-clavulanate; 90 mg/kg/day of amoxicillin, with 6.4 mg/kg/day of clavulanate in 2 divided doses; recommended in children who have taken amoxicillin in the previous 30 days and those with concurrent conjunctivitis or history of AOM unresponsive to
amoxicillin
  Ceftriaxone, 50 mg/kg IM or IV q24h for 3 consecutive days can be reserved for those who are too sick to take oral medications or who unsuccessfully took amoxicillin-clavulanate.
- Neither erythromycin nor trimethoprim-sulfamethoxazole should be used as a second-line agent in treatment failures.
- Recurrent AOM: Antibiotic prophylaxis for recurrent AOM (>3 distinct, well-documented episodes in 6 months) is not recommended (2)[B].

**ISSUES FOR REFERRAL**
- If treating with observation, follow up in 48 to 72 hours if symptoms persist.
- If treating with antibiotics, follow up in 7 to 10 days if symptoms persist.
- Refer to ENT for recurrent COM for consideration of tympanostomy tubes. See “Surgery/Other Procedures” below.

**ADDITIONAL TREATMENT**
Pain control: acetaminophen, ibuprofen, benzocaine drops (additional but brief benefit over acetaminophen)

**SURGERY/OTHER PROCEDURES**
- Recurrent AOM: No definitive guidelines agreed upon as indications for surgery. Can consider referral for surgery if ≥3 episodes of well-documented AOM within 6 months, ≥4 episodes within 12 months with ≥1 episode in previous 6 months, or AOM episodes occur while on chemoprophylaxis.
- Tympanostomy tubes may be effective in selective patients, particularly children age <2 years with recurrent AOM (6)[A].
- Adenotonsillectomy reduced the rate of AOM by 0.7 episodes per child only in the 1st year after surgery and had a 15% complication rate.
- COM: Referral for surgery for tympanostomy should be individualized. It can be considered if >4 to 6 months of bilateral OME and/or >6 months of unilateral OME and/or hearing loss >25 dB or for high-risk individuals at any time.
- Tympanostomy tubes may reduce recurrence of AOM minimally, but it does not lower the risk of hearing loss (3)[B].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
One randomized control study with oral immune stimulating supplements containing Sambucus Nigra, Zinc Tyndallized Lactobacillus acidophilus (H122), Arabinogalactans, Vitamin D, Vitamin E, and Vitamin C was effective in reducing upper airway infections and otitis media with effusion. It is unclear if one vs. all ingredients have effects, but there is increasing evidence for Vitamin D supplement as means of prevention if Vitamin D deficient patients (7)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Outpatient management is appropriate, except if surgery is indicated or for AOM in febrile infants age <2 months or children requiring ceftriaxone who also require monitoring for 24 hours.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients with otitis media who do not respond within 48 to 72 hours should be reevaluated:

- If therapy was initiated, consider changing the antibiotic; options are limited because macrolides have limited benefit against H. influenzae over amoxicillin, and most oral cephalosporins have no improved outcomes.

Patient Monitoring

- AOM: Up to 40% may have persistent middle ear effusion at 1 month, with 10–25% at 3 months.
- OME/COM: Repeat otoscopic or tympanometric exams at 3 months, as indicated, as long as OME persists or sooner if there are red flags (see earlier discussion).

DIET

No specific diets are recommended with otitis media. Oral supplements with some vitamins including Vitamin D may provide some benefit, but effects are not fully understood and require further studies before recommending.

PROGNOSIS

- See “General Measures.”
- Most cases of uncomplicated, non-severe AOM resolve without antibiotics.

COMPLICATIONS

- AOM: Serious complications are rare: tympanic membrane perforation/otorrhea, acute mastoiditis, facial nerve paralysis, otitic hydrocephalus, meningitis, hearing impairment
- COM: Speech and language disabilities may occur. Hearing loss is not caused by OME, but in children who are at risk for speech, language, or learning problems (e.g., autism spectrum, syndromes, craniofacial disorders, developmental delay, and children already with speech/language delay), it could lead to further problems because they are less tolerant of a hearing impairment.
- Recurrent AOM and COM: atrophy and scarring of eardrum, chronic perforation and otorrhea, cholesteatoma, permanent hearing loss, chronic mastoiditis, other intracranial suppurative complications

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithm: Ear Pain/Otalgia

CODES
ICD10
- H65 Nonsuppurative otitis media
- H65.0 Acute serous otitis media
- H65.00 Acute serous otitis media, unspecified ear

CLINICAL PEARLS
- Pneumatic otoscopy is the single most specific and clinically useful test for diagnosis.
- Consider a delay of antibiotics for 24 to 48 hours in uncomplicated presentations (>6 months of age) who do not have severe illness or otorrhea.
- First-line treatment is amoxicillin, 80 to 90 mg/kg/day for 10 days for children age <2 years; consider a 5- to 7-day course in >2 years of age.
- Erythema and effusion can persist for weeks.
- Antibiotics, antihistamines, and steroids are not indicated for COM.
- OME rarely develops in adults. Persistent unilateral effusion should be investigated to rule out neoplasm, particularly if there is a cranial nerve palsy.
OTITIS MEDIA WITH EFFUSION
Hobart Lee, MD, FAAFP

BASICS

DESCRIPTION
- Otitis media with effusion (OME) is defined as the presence of fluid in the middle ear in the absence of acute signs or symptoms of infection.
- More commonly, a pediatric disease
- May occur spontaneously from poor eustachian tube function or as an inflammatory response after acute otitis media (AOM)
- Synonyms: serous otitis media, secretory otitis media, nonsuppurative otitis media, “ear fluid,” or “glue ear”

EPIDEMIOLOGY

Incidence
Approximately 90% of children have OME before school age, mostly between the ages of 6 months and 4 years.

Prevalence
- Approximately 2.2 million new cases annually in the United States
- Less prevalent in adults and is usually associated with an underlying disorder

ETIOLOGY AND PATHOPHYSIOLOGY
- Chronic inflammatory condition where an underlying stimulus causes an inflammatory reaction with increased mucin production creating a functional blockage of the eustachian tube and thick accumulation of mucin-rich middle ear effusion
- Young children are more prone to OME due to shorter and more horizontal eustachian tubes, which become more vertical around 7 years of age.
- Biofilms, anatomic variations, and AOM caused by viruses or bacteria have been implicated as stimuli causing OME. The common pathogens causing AOM include nontypeable Haemophilus influenzae, Streptococcus pneumoniae, and Moraxella catarrhalis.
- In adults, OME is often associated with paranasal sinus disease (66%), smoking-induced nasopharyngeal lymphoid hyperplasia and adult onset adenoidal hypertrophy (19%), or head and neck tumors (4.8%).

RISK FACTORS
- Risk factors include a family history of OME, early child care, exposure to cigarette smoke, bottlefeeding, and low socioeconomic status (1).
- Eustachian tube dysfunction may be a predisposing factor, although the evidence is unclear (2).
- Gastroesophageal reflux is associated with OME (2).

GENERAL PREVENTION
OME is generally not preventable, although lowering smoke exposure, breastfeeding, and avoiding child care centers at an early age may decrease the risk.
DIAGNOSIS

HISTORY
- OME is transient and asymptomatic in many pediatric patients.
- Most common reported symptom is hearing loss (2). There may be mild discomfort present in the ear, fullness, or “popping.”
- Infants may have ear rubbing, excessive irritability, sleep problems, or failure to respond appropriately to voices or sounds.
- Clinical features may include “a history of hearing difficulties, poor attention, behavioral problems, delayed speech and language development, clumsiness, and poor balance” (2).
- There may be a history of recent or recurrent episodes of AOM or a recent upper respiratory tract infection (2).

PHYSICAL EXAM
- Cloudy tympanic membrane (TM) with distinctly impaired mobility. Air-fluid level or bubble may be visible in the middle ear (1,2).
- Color may be abnormal (yellow, amber, or blue), and the TM may be retracted or concave (2).
- Distinct redness of the TM may be present in approximately 5% of OME cases (1).
- Clinical signs and symptoms of acute illness should be absent in patients with OME (1).

DIFFERENTIAL DIAGNOSIS
- AOM
- Bullous myringitis
- Tympanosclerosis (may cause decreased/absent motion of the TM)
- Sensorineural hearing loss

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other
- The primary standard to make the diagnosis is pneumatic otoscopy, which demonstrates reduced/absent mobility of the TM secondary to fluid in the middle ear. Pneumatic otoscopy has 94% sensitivity and 80% specificity for diagnosing OME. Accuracy of diagnosis with an experienced examiner is between 70% and 79% (1)[C].
- Myringotomy is the gold standard but is not practical for clinical use (2)[C].
- Tympanometry may also be used to support or exclude the diagnosis in infants >4 months old, especially when the presence of middle ear effusion is difficult to determine (1)[C].
- Acoustic reflectometry (64% specificity and 80% sensitivity) may be considered instead of tympanometry (3)[B].
- Audiogram may show mild conductive hearing loss (2)[C].
- Hearing tests are recommended for OME lasting >3 months (1)[C].
- Language testing is recommended for children with abnormal hearing tests (1)[C].

TREATMENT
- OME improves or resolves without medical intervention in most patients within 3 months, especially if secondary to AOM (1)[C].
- Current guidelines support a 3-month period of observation with optional serial exams,
tympanometry, and language assessment during that wait time (1,2)[C].

- Adults found to have OME should be screened for an underlying disorder and treated accordingly (2)[C].

MEDICATION

- The 2016 AAOHNS guideline recommends against routine use of antibiotics in treatment of OME. A 2016 Cochrane review, however, found that children treated with oral antibiotics were more likely to have tympanogram confirmed OME resolution in 2 to 3 months (number needed to treat = 5). Adverse events included diarrhea, vomiting, skin rash, and allergic reactions (number needed to harm = 20). Importantly, there were no reported patient-oriented outcomes (e.g., cognitive development, language, quality of life, or speech). Outcomes regarding short-term hearing, reduction of AOM infections, or need for ventilation tubes are unknown (1)[C],(4)[A].

- The 2016 AAOHNS and a 2006 Cochrane review found that antihistamines and decongestants have no benefit over placebo in the treatment of OME with possible adverse side effects such as insomnia, hyperactivity, and drowsiness (5)[A].

- The 2016 AAOHNS guideline recommends against administering oral or intranasal corticosteroids. No long-term benefit was shown, and adverse side effects such as weight gain and behavioral changes are possible (1)[C].

- In adults, eustachian tube dysfunction secondary to allergic rhinitis or recent upper respiratory infection can be the cause of OME. It is unknown whether decongestants, antihistamines, or nasal steroids improve outcomes in adults.

ISSUES FOR REFERRAL

The following are indications for referral to a surgeon for evaluation of tympanostomy tube placement:

- Chronic bilateral OME (≥3 months) with hearing difficulty
- Chronic OME with symptoms (e.g., vestibular problems, poor school performance, behavioral issues, ear discomfort, or reduced quality of life)
- At-risk children (speech, language, or learning problems due to baseline sensory, physical, cognitive, or behavioral factors) with chronic OME or type B (flat) tympanogram

ADDITIONAL THERAPIES

- Hearing aids may be an acceptable alternative to surgery (2)[C].

- Autoinflation, which refers to the process of opening the eustachian tube by raising intranasal pressure (e.g., by forced exhalation with closed mouth and nose), may be beneficial in improving patients’ tympanogram or audiometry and quality of life scores (6)[B].

SURGERY/OTHER PROCEDURES

- Tympanostomy tubes are recommended as initial surgery. Risks include purulent otorrhea, myringosclerosis, retraction pockets, and persistent TM perforations (1)[C].

- Adenoidectomy with myringotomy has similar efficacy to tympanostomy tubes in children >4 years of age but with added surgical and anesthetic risks (1)[C].

- Adenoidectomy should not be performed in children with persistent OME alone unless there is a distinct indication for the procedure for another problem (e.g., adenoiditis/chronic sinusitis/nasal obstruction) (1)[C].

- Adenoidectomy (and concurrent tube placement) may be considered when repeat surgery for OME is necessary (e.g., when effusion recurs after tubes have fallen out or are removed). In
these cases, adenoidectomy has been shown to decrease the need for future procedures for OME (1,2)[C].
- Tonsillectomy or myringotomy alone is not recommended for treatment (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Children who are at risk for developmental difficulties should be evaluated for OME at the time of diagnosis and at 12 to 18 months (if initial diagnosis occurred <12 months). At-risk conditions include permanent hearing loss independent of OME, suspected or confirmed speech and language delay, autism spectrum disorder or other pervasive developmental disorder, Down syndrome or other craniofacial disorder, blindness or other uncorrectable visual impairment, cleft palate, and unspecified developmental delay (1)[C].
- For patients diagnosed with OME, reevaluation and repeat hearing tests should be performed every 3 to 6 months until the effusion has resolved or until the child develops an indication for surgical referral (1)[C].

**PROGNOSIS**
Approximately 50% of children >3 years of age have OME resolution within 3 months.

**COMPLICATIONS**
- The most significant complication of OME is permanent hearing loss, leading to possible language, speech, and developmental delays.
- Underventilation of the middle ear can cause a cholesteatoma (1)[C].

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- H65.90 Unspecified nonsuppurative otitis media, unspecified ear
- H65.00 Acute serous otitis media, unspecified ear
- H65.20 Chronic serous otitis media, unspecified ear

**CLINICAL PEARLS**
- OME is defined as the presence of a middle ear effusion in the absence of acute signs of infection.
- In children, OME most often arises following an AOM. In adults, it often occurs in association with eustachian tube dysfunction.
- The primary standard for diagnosis is pneumatic otoscopy.
- There is no benefit in antihistamines, decongestants, or corticosteroids for the treatment of OME in children.
- Management usually includes watchful waiting and surgery (when indicated); which strategy is chosen depends on many factors, including the risk/presence of any associated speech, language, or learning delays, and on the severity of any associated hearing loss.
OVARIAN CANCER
Susan L. Zweizig, MD ● Christina Kunycky, MD

BASICS
There are >22,000 new cases of ovarian cancer annually in the United States, and approximately 14,000 women will die of their disease; as such this the most lethal of gynecologic cancers, which accounts for 2.3% of all cancer deaths nationally.

DESCRIPTION
Malignancy that arises from the epithelium (90–95%), sex cord stromal, or germ cells of the ovary as well as tumors metastatic to the ovary. Histologic types include the following:

- Epithelial
  - High grade serous (most common, 70–80%)
  - Low grade serous
  - Mucinous
  - Endometrioid
  - Clear cell
  - Malignant Brenner tumor (transitional cell epithelium)
  - Carcinosarcoma (malignant mixed müllerian tumor)

- Sex cord stromal
  - Granulosa cell tumor
  - Sertoli-Leydig cell tumors
  - Lipid (steroid) cell tumor
  - Fibrosarcoma

- Germ cell
  - Teratoma (immature)
  - Dysgerminoma
  - Embryonal carcinoma
  - Endodermal sinus tumor (yolk sac tumor)
  - Choriocarcinoma

- Metastatic disease from the following:
  - GI tract (Krukenberg tumor)
  - Breast
  - Endometrium
  - Lymphoma

- System(s) affected: GI, genitourinary, endocrine

EPIDEMIOLOGY

Incidence
- 22,440 new cases per year in the United States; 14,070 deaths per year
- Leading cause of gynecologic cancer death in women
- Majority of ovarian cancer is diagnosed at an advanced stage.
- Average age of diagnosis
  - Epithelial: 63 years
Sex cord stromal: 50 years
Germ cell: 10 to 30 years

Prevalence
Lifetime risk for general population: 1 in 78 American women develop ovarian cancer.

Etiology and Pathophysiology
- Malignant transformation of the ovarian epithelium may result from repeated trauma and inflammation during ovulation.
- Ovarian, fallopian tube, and primary peritoneal carcinomas have identical histologic and morphologic features. A higher percentage of ovarian cancers are now known to originate in the fallopian tube and other components of the secondary müllerian system, including primary peritoneal cancers.

Genetics
- Hereditary breast/ovarian cancer syndrome: early-onset breast or ovarian cancer, autosomal dominant transmission with variable penetrance, usually associated with BRCA-1 or BRCA-2 (tumor suppressor gene) mutation
- Lynch syndrome: autosomal dominant inheritance; increased risk for colorectal, endometrial, stomach, small bowel, breast, pancreas, and ovarian cancers; defect in DNA mismatch repair genes

Risk Factors
- 90% of ovarian cancer is sporadic and not inherited, but family history is the most significant risk factor. Multiple relatives with breast or ovarian cancer increase risk: Refer these patients for genetic counseling. Individuals in families with familial cancer syndromes have 20–60% risk of developing ovarian cancer.
- Risk factors: older age, white race, infertility, nulligravidity, early menarche or late menopause, endometriosis, postmenopausal estrogen replacement therapy, residence in an industrialized Western country (i.e., North America, Northern Europe)
- Association between fertility medications and risk of ovarian cancer is controversial, but women with infertility who have a successful live birth do not have an increased risk of ovarian cancer.
- Obesity as a risk factor for ovarian cancer remains inconclusive; some studies do suggest an increased risk with BMI >30 and increased mortality related to BMI >35.

General Prevention
- Use of oral contraceptives: 5 years of use decreases risk by 20%; 15 years of use decreases risk by 50% ([A])
- Multiparity
- Breastfeeding
- Tubal ligation or hysterectomy
- Risk-reducing salpingo-oophorectomy
- Protective effect of aspirin and NSAIDs in ovarian cancer is controversial.
- Recommendations for high-risk (family history of a hereditary ovarian cancer syndrome) population
  - Women should undergo pelvic examinations, CA-125 level measurement, and transvaginal ultrasound (US) every 6 to 12 months beginning at age 30 or 10 years prior to the earliest
age of diagnosis of ovarian cancer in the family.
– Women with family histories of ovarian cancer or premenopausal breast cancer should be referred for genetic counseling.
– Prophylactic oophorectomy is advised for mutation carriers after childbearing is completed or by age 35 years.
  o Risk of primary peritoneal carcinoma remains 1–2% after prophylactic oophorectomy.

Screening: No effective screening exists for ovarian cancer in the general population.
– Routine use of CA-125 and transvaginal US for screening in women of average risk is not recommended. Annual pelvic examinations may be performed, particularly in postmenopausal women. An adnexal mass in a premenarchal female or a palpable adnexa in a postmenopausal female warrants further evaluation.

COMMONLY ASSOCIATED CONDITIONS

- Ascites
- Pleural effusion
- Carcinomatosis
- Bowel obstruction
- Breast cancer
- Endometrial cancer

DIAGNOSIS

HISTORY

- Acute presentation:
  – Shortness of breath (pleural effusion)
  – Nausea, vomiting, decreased oral intake (bowel obstruction)
  – Calf pain, shortness of breath (venous thromboembolism)
  – Severe abdominal or pelvic pain (ovarian torsion or rupture)

- Subacute presentation:
  – Bloating, sense of abdominal fullness, increased abdominal size
  – Early satiety, anorexia, dyspepsia
  – Abdominal or pelvic pain/cramping
  – Dyspareunia
  – Urinary frequency or urgency in absence of infection
  – Fatigue, weight loss
  – Precocious puberty (sex cord stromal or germ cell tumors)

PHYSICAL EXAM

- Pelvic mass
- Cul-de-sac and/or pelvic nodularity (rectovaginal exam)
- Fluid wave (ascites)
- Decreased or absent breath sounds (pleural effusion)
- Abdominal mass (omental caking)
- Cachexia
- Lymphadenopathy
- Hirsutism in androgen-secreting tumors
DIFFERENTIAL DIAGNOSIS
- GI or endometrial malignancies
- Benign or borderline neoplasms
- Tubo-ovarian abscess or hydrosalpinx
- Uterine fibroids
- Endometriomas
- Physiologic cysts
- Irritable bowel syndrome
- Colitis
- Hepatic failure with ascites
- Diverticulitis
- Pelvic kidney

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Obtain with confirmed or suspected disease.
- CBC
- Liver function tests (LFTs) to rule out hepatic disease
- Urinalysis
- Serum albumin
- Tumor markers:
  - Epithelial tumors: CA-125, CA 19-9, CEA
    - CA-125: Levels are elevated in 90% of women with malignant nonmucinous tumors, but 50% of stage I ovarian cancers will have a falsely negative CA-125, and common benign gynecologic conditions (PID, endometriosis, fibroids, pregnancy, menstruation) can cause elevations. In addition, CA-125 levels can be elevated with ascites, pleural effusion, congestive heart failure, pancreatitis, systemic lupus erythematosus, and liver disease.
    - CA 19-9 and CEA: better indicators of disease in mucinous tumors, helpful if GI primary suspected
  - Nonepithelial tumors: inhibin A/B (granulosa cell tumor), HCG (dysgerminoma, choriocarcinoma, embryonal carcinoma), AFP (endodermal sinus tumor, embryonal carcinoma), LDH (dysgerminoma)
- Pelvic (preferably transvaginal) US
- CT abdomen and pelvis scan with contrast
- CXR or CT chest scan to evaluate for pleural effusions or lung nodules

Follow-Up Tests & Special Considerations
- Patients with ovarian cancer should be up to date with screening recommendations—mammograms, Pap smear, and colonoscopy.
- Colonoscopy (or other test to evaluate the colon—barium enema, CT colonography) is needed if a colonic primary is suspected.

Diagnostic Procedures/Other
- Endometrial biopsy if abnormal uterine bleeding present to evaluate for dual primary
- Consider paracentesis or thoracentesis (or IR biopsy of pelvic mass) if patient not an operative candidate.
  - IR biopsy: Epithelial ovarian cancer commonly involves the peritoneal surfaces of the
abdomen and pelvis.

Test Interpretation
Pathologic diagnosis (with surgery, IR biopsy, or cytology) is necessary for definitive diagnosis.

TREATMENT

GENERAL MEASURES
- Surgical exploration with staging and debulking is critical. Optimal cytoreduction of tumor burden enhances effectiveness of adjuvant therapy and is associated with longer survival.
- In patients with bulky advanced disease in epithelial ovarian cancer where optimal cytoreduction with primary surgery is unlikely, it is reasonable to consider neoadjuvant chemotherapy (NACT), preoperative chemotherapy, after consultation with a gynecologic oncologist (2)[A].

MEDICATION

First Line
- After surgery, most patients will require chemotherapy or adjuvant therapy. Those with stage IA, grade 1, and most stage IB, grade 1 tumors who are optimally staged do not require adjuvant therapy. Patients with clear cell histology, grade 3 tumors, or tumors stage IC or worse do require adjuvant therapy. Patients should be encouraged to participate in clinical trials whenever possible.
- Adjuvant chemotherapy in early stage epithelial ovarian cancer: carboplatin IV and paclitaxel (Taxol) IV every 3 weeks for 6 cycles
- Adjuvant chemotherapy in advanced stage epithelial cancer for patients with optimal cytoreduction: paclitaxel (Taxol) IV on day 1, cisplatin intraperitoneal (IP) on day 2, and paclitaxel (Taxol) IP on day 8 to repeat every 21 days for 6 cycles
- Women with suboptimal cytoreduction are not candidates for IP chemotherapy. Instead, recommend carboplatin IV every 3 weeks with paclitaxel (Taxol) weekly (or every 3 weeks) for 6 cycles.
- IP chemotherapy in combination with IV chemotherapy improves survival in advanced ovarian cancer. However IP chemotherapy is associated with more toxicity. New evidence suggests that dose-dense IV therapy with bevacizumab may yield similar results while minimizing toxicity.
- Germ cell or sex cord–stromal cancers: bleomycin, etoposide, and cisplatin IV
- Contraindications to chemotherapy: poor functional status, excessive toxicity, hypersensitivity
- Precautions: All regimens cause bone marrow suppression. Cisplatin is associated with ototoxicity, renal toxicity, and peripheral neuropathy. Paclitaxel (Taxol) can cause neuropathy and alopecia.
- Antiemetics: ondansetron (Zofran), aprepitant (Emend), metoclopramide (Reglan), prochlorperazine (Compazine), promethazine (Phenergan)

Second Line
- Liposomal doxorubicin (Doxil)
- Carboplatin/gemcitabine
- Topotecan
Etoposide
Bevacizumab
Cyclophosphamide
Tamoxifen

ADDITIONAL THERAPIES
- Patients receiving NACT typically receive subsequent interval surgery for debulking of disease if there is a good response to treatment followed by additional cycles of chemotherapy after surgery.
- Given high risk of recurrence, patients with a known BRCA1 or BRCA2 mutation are placed on FDA-approved PARP inhibitor Olaparib after completion of primary treatment for maintenance therapy (3).

SURGERY/OTHER PROCEDURES
- For epithelial malignancies, staging and tumor excision/debulking include the following:
  - Cytologic evaluation of peritoneal fluid (pelvic washings)
  - Bilateral salpingo-oophorectomy with total hysterectomy and tumor reductive surgery
  - Excision of omentum
  - Inspection and palpation of peritoneal surfaces
  - Cytologic smear of right hemidiaphragmatic surface
  - Biopsy of adhesions or any suspicious areas
  - Biopsies of paracolic recesses, pelvic sidewalls, posterior cul-de-sac, and bladder peritoneum
  - Bilateral pelvic and paraaortic lymph node biopsies
  - Appendectomy for mucinous tumors or if appendix appears abnormal
- Goal of surgery is optimal cytoreduction (<1 cm of maximum tumor diameter remaining).
- Germ cell or sex cord–stromal cancers (less likely to be bilateral): salpingo-oophorectomy (unilateral if only one ovary involved) in young patient for fertility sparing management

COMPLEMENTARY & ALTERNATIVE MEDICINE
CAM (complementary and alternative medicine) treatments such as cognitive distraction, exercise, hypnosis, and relaxation may be used by patients to mitigate effects of chemotherapy such as nausea, diarrhea, fatigue, and hair loss. However, these lack quality evidence regarding their true effectiveness.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Surgical patients should follow up within 2–4 weeks for post-operative assessment and then for further treatment planning. Patient undergoing chemotherapy should have regular visits to assess toxicity and disease progression.

Patient Monitoring
- Physical exam every 3 months for the first 2 years after diagnosis, every 6 months until 5 years, and then annually thereafter
- If CA-125 elevated at diagnosis, follow levels after treatment to detect recurrence.
- Germ cell/sex cord–stromal cancer: physical exam and tumor markers every 3 months for the
first 2 years after diagnosis and then annually
- Tumor markers for sex cord–stromal cancers should be checked every 6 months for 10 years because recurrences can occur remote from initial diagnosis.
- CT scan of chest, abdomen, and pelvis and/or PET scan when recurrence suspected
- Routine screening with imaging not recommended

**PATIENT TEACHING**
Patients should be educated on signs and symptoms of recurrence including pelvic or abdominal pain/discomfort, bloating, and early satiety.

**PROGNOSIS**
- Recurrence rates for epithelial cancer
  - Early-stage disease: 20%
  - Advanced disease: >80%
- 5-year survival rates for ovarian cancer based on International Federation of Gynecology and Obstetrics (FIGO) data

**COMPLICATIONS**
- Pleural effusion
- Pseudomyxoma peritonei
- Ascites
- Toxicity of chemotherapy
- Bowel obstruction
- Malnutrition
- Electrolyte disturbances
- Fistula formation

**REFERENCES**

**CODES**

**ICD10**
- C56.9 Malignant neoplasm of unspecified ovary
- C56.1 Malignant neoplasm of right ovary
- C56.2 Malignant neoplasm of left ovary

**CLINICAL PEARLS**
- Family history of ovarian cancer or early-onset breast cancer is the most significant risk factor for the development of ovarian cancer, yet the vast majority of cases remain sporadic.
- The diagnosis of ovarian cancer should be suspected in women with persistent bloating, upper abdominal discomfort, or GI symptoms of unknown etiology.
OVARIAN CYST, RUPTURED
Glency Sue Marie S. Corominas, MD • Adriana Arocha, MD • Marcy Wiemers, MD

**BASICS**
- Ovarian cysts are frequent in reproductive-age women.
- Most ovarian cysts are benign physiologic follicles created by the ovary at the time of ovulation.
- Ovarian cysts can cause symptoms when they become enlarged and exert a mass effect on surrounding structures, or when they rupture and the cyst contents irritate the peritoneum or nearby pelvic organs.
- Patients with a symptomatic ruptured cyst usually complain of acute onset unilateral lower abdominal pain.
- Rupture can be caused by sexual intercourse, luteal phase, exercise, trauma, pregnancy, or be idiopathic.
- Evaluation of the patient should include exclusion of other emergent causes: ectopic pregnancy, ovarian torsion, and nongynecologic sources of acute unilateral lower abdominal pain.
- Once the diagnosis of a ruptured cyst is confirmed, most patients can be managed conservatively as outpatients with adequate pain control. Surgical intervention is rarely indicated.
- Oral contraceptive pills (OCPs) are not an effective treatment for existing ovarian cysts.

**DESCRIPTION**
A suspected ruptured ovarian cyst should be treated as an unknown adnexal mass (mass of the ovary, fallopian tube, and surrounding tissue) until proven otherwise.

**EPIDEMIOLOGY**
- The actual incidence of ovarian cysts is difficult to calculate as many ruptured cysts are asymptomatic or found incidentally.
- Ovarian cysts can be seen on transvaginal ultrasounds in nearly all premenopausal women and in up to 18% of postmenopausal women. The vast majority of these cysts are benign or functional.
- Most ruptured ovarian cysts are physiologic events and self-limited. Expectant management with pain control is usually sufficient.
- About 13% of ovarian masses in reproductive-age women are malignant, as opposed to 45% in postmenopausal women. About 70% of ovarian malignancies are diagnosed at a late stage.
- Ruptured ovarian cysts most commonly affect the right ovary (63%).

**Incidence**
About 7% of women worldwide experience a symptomatic cyst during their lifetime.

**Prevalence**
During pregnancy, prevalence varies from 1 to 5.3%; of those, just 0.63% are symptomatic and 1% malignant.
ETIOLOGY AND PATHOPHYSIOLOGY
Normal ovulation occurs when a follicle matures and ruptures, releasing an oocyte, leaving a corpus luteum, which subsequently involutes. If the follicle fails to rupture and continues growing, a follicular cyst is formed. If a corpus luteum fails to involute and continues growing, then a corpus luteum cyst occurs. These are the most common cysts. Both types are physiologic (termed “functional”) without malignant potential. Other cyst types include endometriomas (filled with menstrual blood), dermoid cysts that contain mature tissue of ectodermal, mesodermal, and/or endodermal origin, and ovarian malignancy originating from any of the structures of the ovary.

RISK FACTORS
Medications or conditions associated with increased ovulation and/or increased risk of cyst rupture:
- Ovulation induction agents (i.e., Clomid, aromatase inhibitors, GnRH agonists)
- Tamoxifen increases the risk of ovarian cysts in reproductive-age women.
- Polycystic ovarian syndrome (PCOS; common)
- Fibrous dysplasia/McCune-Albright syndrome (rare)
- Ovarian endometriosis

GENERAL PREVENTION
Ovulation suppression with combined oral contraceptives is the mainstay therapy for prevention of recurrent ovarian cyst.

COMMONLY ASSOCIATED CONDITIONS
- Endometriomas located adjacent to the ovaries are found in 20–55% of women with endometriosis.
- PCOS

DIAGNOSIS
- The characteristic symptoms of ruptured cyst may resemble ectopic pregnancy. Ectopic pregnancy should be ruled out when a ruptured cyst is suspected (1)[C].
- Sonographic imaging along with CT and MRI can aid in diagnosis of gynecologic emergencies (2)[C].
- CT is useful to confirm a hemoperitoneum, and MRI can assist when the diagnosis remains unclear after CT and ultrasound (2)[C].
- Ultrasound and CT imaging for diagnosis has decreased the need for diagnostic surgical intervention (3)[B].
- In addition, ultrasound is useful in confirming normal Doppler flow to the affected ovary and adnexa (1)[C].

HISTORY
- Questions that should be addressed if a ruptured ovarian cyst is suspected include:
  - Onset and characteristics of pain
  - Pain associated with timing of sexual intercourse, strenuous activity, or trauma
  - Date of last menstrual period
  - Presence or absence of vaginal bleeding
– Nausea or vomiting
– Shoulder or upper abdominal pain due to subphrenic extravasation

Symptoms of hypotension/hypovolemia, including palpitations, shortness of breath, sensation of being hot or clammy, dizziness

In addition, information that will guide diagnosis should include patient age, known or previous ovarian cysts, and reproductive history

**ALERT**

Patients with bleeding diathesis or undergoing anticoagulation therapy may experience significant bleeding from hemorrhagic cysts.

**PHYSICAL EXAM**

Vital signs are usually normal unless significant blood loss has occurred.

Rupture characterized by significant blood loss may be present in the form of pallor, pale mucosal membranes, and tachycardia.

Patients will have significant tenderness to palpation or an acute abdomen if the peritoneum is irritated or inflamed.

On some occasions, a palpable adnexal mass can be felt on bimanual exam. Care should be taken not to cause further injury with a forceful exam.

**DIFFERENTIAL DIAGNOSIS**

Includes all causes of acute abdominal pain, both gynecologic and nongynecologic

Ectopic pregnancy should always be excluded with a negative pregnancy test (1)[C].

Common gynecologic etiologies include:
– Functional ovarian cysts
– Ovarian torsion
– Tubo-ovarian abscess
– Teratomas
– Fibroids
– Endometrioma
– Cystadenoma (mucinous or serous)
– Hydrosalpinx

Malignant gynecologic etiologies can usually be attributed to the various gynecologic cancers of the reproductive tract.

Benign nongynecologic causes of acute lower abdominal pain include:
– Appendicitis
– Diverticulitis
– Infections of the urinary tract
– Renal colic

Malignant nongynecologic causes of acute lower abdominal pain can be attributed to neoplastic processes of the lower GI tract.

**DIAGNOSTIC TESTS & INTERPRETATION**

In all premenopausal women, pregnancy must be ruled out by a urine test. Serial quantitative β-hCG tests are helpful in evaluating an ectopic pregnancy (1)[C].

Complete blood count may reveal a significant drop in hematocrit if there is ongoing hemorrhage (3)[B]. Leukocytosis should raise the suspicion of an infectious process (1)[C].

Urinalysis and STD testing should be obtained to evaluate for infectious causes, PID, or
symptomatic renal stones (1)[A].
- A type and screen is indicated if surgical intervention is planned or blood products are being considered.
- Ultrasonography is the first-line imaging modality (1)[C].
- CA-125 may assist in evaluation but can be elevated in a number of conditions (1)[C].

**Initial Tests (lab, imaging)**
- Ultrasonography
- Serial quantitative β-hCG
- Complete blood count
- Urinalysis and STD Testing

**Follow-Up Tests & Special Considerations**
Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) may narrow the differential diagnosis when ultrasonography is indeterminate.

**Diagnostic Procedures/Other**
Laparoscopy may be diagnostic and therapeutic in emergent cases.

---

**TREATMENT**

**GENERAL MEASURES**
- For many patients, pain associated with a ruptured cyst will be transient and self-limiting.
- Cyst rupture in a stable healthy patient can be managed conservatively in 80% of cases (3)[B].
- Patient with anticoagulation can also be managed conservatively with cyst rupture using a multidisciplinary team (4)[C].
- Scheduled NSAIDs or oral narcotics can be prescribed depending on pain severity.
- For patients with multiple episodes or a single severe occurrence, OCPs can be considered for ovulation suppression and prevention. They are not effective for treatment of ovarian cysts that are already present (5)[A].
- Unstable patients with hemodynamic compromise or patients with significant hemoperitoneum should be resuscitated, and laparoscopy or a laparotomy should be considered. Surgical exploration should also be considered if there is a concern for malignancy.

**ISSUES FOR REFERRAL**
- **OB/GYN**
  - Consider referral to an obstetrician if an adnexal mass is diagnosed during pregnancy. Such masses have a low risk of malignancy or acute complication for the pregnancy.
  - Most cysts resolve without intervention within 2 to 3 weeks; those that do not resolve in 12 weeks require prompt referral for surgical assessment (5)[A].
- **Gynecologic oncology**
  - Referral to a gynecologic oncologist should be considered for complex adnexal masses with an elevated CA-125 and associated symptoms concerning malignancy such as ascites, thick septation noted on ultrasound, early satiety, pleural effusion, enlarging abdominal mass, or bowel obstruction.
- **General surgery**
  - Acute lower abdominal pain that is nongynecologic and suspicious for bowel involvement
should be referred to general surgery or a gastroenterologist.

ADDITIONAL THERAPIES
Guided cyst aspiration is not recommended for either diagnosis or treatment but could be considered in patients at high risk who are not good surgical candidates.

SURGERY/OTHER PROCEDURES
- Although the need for surgical intervention is rare, it is usually of an emergent nature.
- Patients with a low diastolic blood pressure and a large amount of hemoperitoneum often need surgery (3)[B].
- In most cases, laparoscopy is diagnostic and therapeutic. The decision to proceed with cystectomy or oophorectomy should be made intraoperatively after a thorough evaluation of the intra-abdominal environment has been completed.
- The advantages of a laparoscopic approach include a shorter length of stay, faster recovery, small scar, and few adhesions. Postoperative recovery time as well as patient satisfaction is significantly improved with a minimally invasive approach.
- Laparotomy should be performed in cases of critical hemodynamic instability or lack of laparoscopically trained surgeons. If there is concern for malignancy or metastases, laparotomy may be the preferred method of surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients who require inpatient management should be managed with serial abdominal exams, analgesia, and intravenous resuscitation as indicated by their initial presentation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Follow-up for patients managed conservatively should be scheduled in 72 hours from the initial onset of symptoms. Patients should present sooner for new or worsening symptoms.
- Patients with complete resolution of symptoms within a few days can follow up as needed. However, these patients should be counseled on risk of reoccurrence and options for prevention.
- In patients who had surgery, post-op follow-up should be scheduled 2 weeks from the date of surgery.
- Patients in whom an ovarian cyst was diagnosed incidentally should follow up based on the size of their cyst.

Pregnancy Considerations
- The management of adnexal masses during pregnancy is controversial.
- Most adnexal masses in pregnancy can be managed expectantly because the risk of malignancy is low (1)[C]. If there is a risk for ruptured endometriotic cyst, early surgical intervention can reduce the risk of cyst fluid leakage, thus preventing adhesions and preserving fertility. MRI can help further characterize a mass safely in pregnancy (1)[C]. However, the possible risk of torsion or rupture should not be considered as an indication for surgery.

PATIENT EDUCATION
Reassurance of the benign nature of most ovarian cysts is an important cornerstone of patient
education.

COMPLICATIONS

- Surgical procedure complications related to any laparoscopic surgery
- Ovarian Reserve Reduction may occur following any ovarian surgery. Desire for future fertility should be factored into surgical decisions. Cysts with a diameter of 5 cm or more can themselves cause compromise in ovarian reserve. It is unclear if the effect is temporary or permanent.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- N83.20 Unspecified ovarian cysts
- N83.0 Follicular cyst of ovary
- N83.1 Corpus luteum cyst

**CLINICAL PEARLS**

- Functional ovarian cysts are very common in reproductive-age women and are usually self-limiting.
- Always exclude ectopic pregnancy.
- Management of symptomatic ruptured cysts is usually accomplished with outpatient pain control and follow-up.
- In cases where a patient with a ruptured cyst is unstable or presents with signs of an acute abdomen, surgical intervention is indicated.
PALLIATIVE CARE
Erika Zimmons, DO, MS

BASICS
Palliative care focuses on preventing and alleviating the suffering of patients (and their families) living with life-limiting illness at any stage.

DESCRIPTION
• The principal goal of palliative care is to prevent and alleviate suffering—whether physical (pain, breathlessness, nausea, etc.), emotional, social, or spiritual regardless of the underlying diagnosis.
• Palliative care is an interdisciplinary approach to caring for patients and families.
• Palliative care aims to improve or maintain quality of life for patients and families despite serious illness.
• The palliative care team often helps to identify the goals of care for the patient based on their preferences and values.
• Palliative care is available for patients with serious, life-limiting illness, at any stage of their disease, with or without concurrent curative care.
• Patients and their families may access palliative care services in the hospital, rehabilitation or skilled nursing facility, and ambulatory setting.
• Hospice: In the United States, hospice is available for patients whose average life expectancy is 6 months or less and whose principal goal is to stay at home (including long-term care or assisted living facility), avoid hospitalizations, and forego disease-directed care with a curative intent. Unlike regular home nursing services, hospice does not require a patient to be homebound. Hospice offers backup support for patients 24 hours a day and 7 days per week.

COMMONLY ASSOCIATED CONDITIONS
Common symptoms/syndromes encountered in palliative care:
• Pain
  – Chronic pain
  – Neuropathic pain
  – Pain from bone metastases
• GI symptoms (~60% incidence)
  – Ascites
  – Anorexia/cachexia
  – Nausea (and vomiting)
    o Consider underlying etiology and treat accordingly.
      ▪ GI causes: constipation, bowel (full or partial) obstruction, ileus, heartburn, reflux, inflammation
      ▪ Intrathoracic causes: cardiac, effusions (cardiac, pulmonary), mediastinal causes, esophageal disease
      ▪ Autonomic dysfunction
      ▪ Centrally mediated: intracranial pressure change, inflammation, cerebellar, vestibular, medication or metabolic cause stimulating vomiting center, and/or chemoreceptor trigger zone
– Bowel obstruction
– Constipation and impaction of stool
– Diarrhea
– Dysphagia
– Mucositis/stomatitis
– Sialorrhea

● General medical
  – Delirium (40–85%)

● Pulmonary symptoms
  – Cough, chronic
  – Breathlessness or dyspnea (60%), which may be due to heart failure, COPD, lung cancer, etc.

● Psychological symptoms
  – Anxiety
  – Depression
  – Insomnia

● Skin
  – Decubitus ulcer
  – Pruritus
  – Complex wounds (fungating tumors, etc.)

DIAGNOSIS
A useful tool in palliative care is the PEACE tool. This tool evaluates (1):

● Physical symptoms
● Emotive and cognitive symptoms
● Autonomy and related issues
● Communication: contribution to others and closure of life affairs–related issues
● Economic burden and other practical issues, including transcendent and existential concerns

HISTORY
A comprehensive palliative care assessment includes:

● Underlying medical conditions and associated physical symptoms
● Communication with empathic inquiry and open-ended questions
● Comprehensive pain assessment and review of systems (e.g., Edmonton Symptom Assessment Scale)
● Psychological symptom assessment
● Cultural, social, financial, and practical concerns
● Spiritual and existential issues
  – FICA assessment (Faith, Importance and influence, Community, Address—how does the patient wish these items to be addressed?) (2)
  – HOPE (sources of Hope/strength/comfort, Organized religion’s role, Personal spirituality and practices, Effects on medical care and end-of-life care) (3)

● Presence and sources of suffering
● Goals of care: posthospital care, practical needs, hopes, and fears
● Prognosis: functional status and interest in knowing prognosis
PHYSICAL EXAM
The physical examination is directed by underlying diagnosis, symptoms, and functional decline in the context of meeting the goals of the patient and family to maximize function, comfort, and support.

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Laboratory and radiology testing depends upon the underlying diagnosis and any associated symptoms. It is important to avoid unnecessary testing.

TREATMENT
GENERAL MEASURES
- Targeted interventions to maximize quality of life and minimize symptom burden considering patient values, goals, fears, and social setting
- Treatment should involve an interdisciplinary team to address potential and realized suffering (physical, emotional, social, and/or spiritual).

MEDICATION
- Minimize polypharmacy; discontinue medications that offer little improvement in the quality of life.
- Focus the use of medications on symptom management.
- Continue use of disease-modifying medications, especially if they lessen symptom burden and enhance immediate quality of life.
- Improve compliance by addressing
  - Pain
    - Use immediate-release opioids—titrate to adequate control.
    - Once pain is controlled, convert to long-acting opioids with short-acting agents made available because tolerance develops and/or patient develops breakthrough pain.
  - Bone pain: NSAIDs added to narcotics are more effective than narcotics alone.
  - Neuropathic pain: may use adjuvant treatment, such as gabapentin or other anticonvulsants. Glucocorticoids may also help.

ALERT
Avoid morphine in patients with renal failure; can induce delirium, hyperalgesia, agitation, and seizures
- Vomiting associated with a particular opioid may be relieved by substitution with an equianalgesic dose of another opioid or a sustained-release formulation (4).
  - Dopamine receptor antagonists (metoclopramide, prochlorperazine) may improve nausea symptoms.
  - Droperidol: insufficient evidence on the use for the management of nausea and vomiting
- Constipation: Consider prophylactic stool softeners (docusate), stimulants (bisacodyl or senna), or osmotic laxatives.

ALERT
Consider laxatives with opioid treatment to avoid constipation.
Subcutaneous methylnaltrexone may be used for inducing bowel movements without inducing withdrawal in opioid-induced constipation.

Dyspnea: Consider oxygen. Consider benzodiazepines if increased anxiety.
- Treat the underlying cause of breathlessness. In addition, as the disease advances, low-dose opioids may be beneficial to patients (5)[C]. Immediate-release opioids PO/IV treat dyspnea effectively and typically at doses lower than necessary for the relief of moderate pain.

Delirium: lowest doses necessary of benzodiazepines or antipsychotics (haloperidol or risperidone, etc.)
- Monitor patient safety and use nonpharmacologic strategies to assist orientation (clocks, calendars, environment, and redirection).

Pruritus: no optimal therapy

Anxiety: insufficient data for recommendations of specific medication

Megestrol acetate improves appetite and slight weight gain in patients with anorexia-cachexia syndrome.

ISSUES FOR REFERRAL

- Referral to palliative care
  - Any patient with a serious, life-limiting illness who could use help with burdensome symptoms or suffering and/or complex goals of care discussion
  - Early referral to palliative care may improve quality of life and longevity for patients with advanced cancer.

- Referral to hospice care
  - Any patient with an average life expectancy of 6 months or less
  - Consider the question, “Would you be surprised if the patient died within the next 6 months?” If the answer is no, they likely meet criteria for hospice.
    - Consider patients who have multiple hospitalizations and/or emergency department visits in the prior 6 months.
    - Refer to local hospice guidelines for additional disease-specific criteria.

REFERENCES

CODES

ICD10
Z51.5 Encounter for palliative care
CLINICAL PEARLS

- Palliative care is a holistic approach to providing comfort to the dying patient.
- Early referral to palliative care helps enhance the quality of life of patients living with serious illness.
- The addition of adjuvant treatments may be more effective than narcotics alone for managing pain.
- Use laxatives with opioid treatment to avoid constipation.
BASICS

DESCRIPTION
- Adenocarcinoma of the exocrine pancreas (90% of pancreatic cancers) is the fourth most common cause of cancer death in the United States and the ninth most common cancer in women.
- Rarely curable: overall 5-year relative survival rate of 9%
- 60% occur in the head, 20% in the body and tail, and 20% diffusely involve the gland.
- As few as 9% are localized at diagnosis. For localized, small cancers (<2 cm) with no lymph node metastases and no extension beyond the capsule, surgical resection has 5-year survival of about 29%.
- Majority of tumors have metastasized at diagnosis and are thus, largely incurable and have a 5-year survival rate of 2–3%.
- In apparently resectable disease, 20–40% have unresectable lesions at surgery.
- Ampullary, duodenal, or distal bile duct tumors may mimic pancreatic carcinoma and are more likely to be resectable and curable.
- For advanced or unresectable cancers, survival is <1% at 5 years; most patients die within 1 year.

EPIDEMIOLOGY
During 2003 to 2007, median age at diagnosis was 70 years; rare <40 years; after 45 years of age, occurrence rises.

Incidence
- According to the American Cancer Society, an estimated 56,770 diagnoses and 45,750 deaths in the United States in 2019
- About 3% of all cancers and about 7% of cancer deaths
- Lifetime risk is about 1 in 64 (1.6%).
- More common in black and white races, 16.7 and 10.3 in 100,000 men and 14.4 and 10.3 in 100,000 women, respectively. Among Hispanic and Asian/Pacific Islanders, there is an incidence of 10.9 and 8.3 in 100,000 men and 10.1 and 8.3 in 100,000 women, respectively.

Prevalence
In 2016 in the United States, ~73,554 people were alive who had a history of pancreatic cancer.

RISK FACTORS
- Smoking: relative risk (RR) 2 to 3; correlates with amount smoked
- Diabetes: RR 2.1 (95% CI 1.6–2.8); 1 in 6 become diabetic within 6 months before diagnosis.
- Prior partial gastrectomy or cholecystectomy: 2- to 5-fold increased risk 15 to 20 years after gastrectomy
- Familial aggregation/genetic factors: 5–10% of patients have a first-degree relative with the disease, which confers a 9-fold increase in risk versus the general population; subgroup may carry germline mutations of DNA repair genes (BRCA2).
Hereditary chronic pancreatitis (autosomal dominant, highly penetrant): Cumulative risk by ages 50 and 75 years is 10% and 54%, respectively.

- Peutz-Jeghers syndrome: RR 30 to 40
- Familial atypical multiple mole and melanoma syndrome (p16): RR 10 to 20
- Hereditary nonpolyposis colon cancer (Lynch syndrome): RR 4
- Sporadic chronic pancreatitis
- Non–O blood type: RR 1 to 2
- High dietary fat, red meat, obesity, Helicobacter pylori
- Alcohol: Recent data indicate a modest increase in risk confined to heavy alcohol consumers.
- Coffee intake and NSAID use NOT regarded as risk factors

**GENERAL PREVENTION**

No effective screening modality exists to detect early cancer. Even with a strong family history or predisposition syndromes, use and cost-effectiveness of screening are unclear.

**COMMONLY ASSOCIATED CONDITIONS**

- Chronic pancreatitis, diabetes mellitus, cystic fibrosis
- KRAS mutations are present in >90% of pancreatic ductal adenocarcinomas.
- Mutation inactivation of tumor suppressors (SMAD4, p53, CDKN2A) allows for tumor progression.
- Subsets of familial pancreatic cancer involve germline cationic trypsinogen or PRSS1 mutations (hereditary pancreatitis), BRCA2 mutations (usually with hereditary breast–ovarian cancer syndrome), CDKN2 mutations (familial atypical mole, multiple melanoma), or DNA repair gene mutations (e.g., ATM and PALB2, apart from BRCA2).
- Majority of familial pancreatic cancers have no genetic underpinnings.
- Precursor lesions are potentially curable—pancreatic intraepithelial neoplasia, intraductal papillary mucinous neoplasm, and mucinous cystic neoplasms.

**DIAGNOSIS**

**HISTORY**

- Depends on tumor location; majority become symptomatic late in disease. About 60–70% of pancreatic cancers develop in the pancreatic head and block the periampullary bile duct, causing obstructive jaundice.
- Weight loss 90%; pain 75% (progressive midepigastric dull ache that often radiates to the back); malnutrition 75%; jaundice 70%; anorexia 60%; pruritus 40%; diabetes mellitus 50%; weakness, fatigue, malaise 30–40%; alcoholic stools, dark urine, steatorrhea; depression is common.
- Pancreatic cancer is a consideration in acute pancreatitis in the elderly and with new-onset diabetes, but most new-onset diabetes are not associated with cancer; thus, evaluation for cancer is warranted only in selected cases.
- Uncommon: unexplained thrombophlebitis; acute pancreatitis from tumor obstruction of pancreatic duct; duodenal obstruction or GI bleeding

**PHYSICAL EXAM**

- Muscle wasting and malnutrition are common; skin lesions are indicative of pruritus. Exam can be normal.
- Palpable abdominal mass or ascites in 20%
- Jaundice: 70% if tumor obstructs bile duct; 10% with body or tail carcinoma
- Courvoisier sign (painless jaundice with a palpable gallbladder): uncommon; usually associated with pancreatic head tumors, periampullary or primary bile duct tumors; hepatomegaly in advanced disease
- Virchow node (left supraclavicular) and Sister Mary Joseph node (umbilical) in metastatic disease; palpable rectal shelf (nonspecific sign of carcinomatosis)
- Migratory thrombophlebitis (Trousseau sign) (uncommon) due to hypercoagulability in mucin-producing pancreatic cancer
- GI bleeding from tumor erosion into adjacent viscera (colon); portal hypertension-related bleeding (uncommon)
- Pancreatic panniculitis: subcutaneous areas of nodular fat necrosis

DIFFERENTIAL DIAGNOSIS
- Chronic pancreatitis, duodenal cancer, cholangiocarcinoma, lymphoma, islet cell tumor, sarcoma, cystic neoplasms, tumor metastatic to pancreas (rare)
- Nonmalignant conditions: choledocholithiasis, acute or chronic pancreatitis, biliary tract stricture, adenoma; chronic mesenteric ischemia
- Tuberculosis or fungal abscess in AIDS
- Patients may present with back pain mimicking musculoskeletal disease.

DIAGNOSTIC TESTS & INTERPRETATION
- Cross-sectional imaging (usually CT scan as first-line choice) to evaluate symptoms or abnormal lab results (1)[B]
- Endoscopic ultrasound (EUS)-guided biopsy: best modality for tissue diagnosis; sensitivity 75–90%; specificity ~100% for diagnosis of a mass (1)[A]
- Routine laboratory tests may reveal elevated serum bilirubin and alkaline phosphatase (cholestasis), anemia, or decreased serum albumin (malnutrition).

Initial Tests (lab, imaging)
- Most patients do not require measurement of serum tumor markers (CA19-9) for diagnosis or management. Some evidence suggests use in predicting outcome and response to adjuvant chemotherapy.
- CEA and CA19-9 are not recommended as screening tests; useful in following patients with known disease (2)[A]
- Elevated CA19-9 antigen: 80% sensitivity; 90% specificity; individuals with Lewis-negative blood group antigen phenotype (5–10%) are unable to synthesize CA19-9; elevations can occur in benign pancreatic or biliary diseases and in nonpancreatic malignancy.
- MUC5AC helps in differentiation.

Follow-Up Tests & Special Considerations
- During therapy, increase in CA19-9 may identify progressive tumor growth. Normal CA19-9 does not exclude recurrence.
- CT scan (pancreatic protocol) using thin section, multiphase multidetector helical CT with a pancreatic protocol is the choice for diagnosis and staging: 85–90% sensitivity; 90–95% specificity; useful for evaluation of distant metastasis and prediction of resectability.
- Abdominal ultrasound (US): common initial test to assess jaundice and duct dilatation; less sensitive than CT for pancreatic masses
- EUS is accurate for tissue biopsy, local tumor and node staging, predicting vascular invasion (90% specificity; 73% sensitivity), and when no mass is identified on CT.
- Endoscopic retrograde cholangiopancreatography (ERCP): 90% sensitivity; 95% specificity for ductal cancer; useful if endoscopic stent is indicated for biliary obstruction; generally confined to high probability for therapeutic intervention on biliary or pancreatic ductal systems
- MRI: no advantage over contrast-enhanced CT
- MR cholangiopancreatography: 90% sensitivity; 95% specificity. Preferred in specific settings: gastric outlet or duodenal stenosis or after surgical rearrangement (Billroth II) or ductal disruption; to detect bile duct obstruction after attempted ERCP is unsuccessful or provides incomplete information
- Cystic pancreatic lesions may be benign or malignant; must be differentiated from pancreatic pseudocysts. Cystadenocarcinomas have better prognoses than typical pancreatic cancers.

**Diagnostic Procedures/Other**
- Percutaneous fine-needle biopsy with US or CT guidance: 80–90% sensitivity; 98–100% specificity
- EUS-guided biopsy: 85–90% sensitivity; virtually 100% specificity for pancreatic mass
- Staging laparoscopy and US: 92% sensitivity; 88% specificity; 89% accuracy
- Positive peritoneal cytology has a positive predictive value of 94%, specificity of 98%, and sensitivity of 25% for determining unresectability.
- PET scan: 90% sensitivity but 70% specificity; limited anatomic information
- Tumor staging
  - Stage Ia: T1 N0 M0 (tumor ≤2 cm)
  - Stage Ib: T2 N0 M0 (tumor >2 cm and ≤4 cm)
  - Stage IIa: T3 N0 M0 (tumor >4 cm)
  - Stage IIb: T1–T3 N1 M0 (N1 is metastasis in 1 to 3 regional lymph nodes.)
  - Stage III: T1–T3 N2 M0 (N2 is metastasis in ≥4 regional lymph nodes), T4 any N M0 (Tumor involves celiac axis, superior mesenteric artery, and/or common hepatic artery, regardless of size.)
  - Stage IV: any T any N M1 (distant metastases)

**Test Interpretation**
- Duct cell carcinoma: 90%
- Other less common tumors: acinar, papillary mucinous, signet ring, adenosquamous, mucinous, giant or small cell, cystadenocarcinoma, undifferentiated, unclassified carcinoma

**ALERT**
Chronic pancreatitis can present with similar pain, weight loss, jaundice, and an inflammatory mass on imaging.

**TREATMENT**
- Surgical resection: only chance of cure; no role for pancreatic resection in metastatic disease. As few as 15–20% are candidates for resection.
- Criteria for unresectability: extrapancreatic spread, encasement or occlusion of major vessels, distant metastases
- New combination chemotherapy regimens may offer advantages over gemcitabine. Standard
therapies remain unsatisfactory; thus, patients should be considered for clinical trials (2)[B].

**MEDICATION**

- **Analgesics**
- **Stages I and II**
  - Radical pancreatic resection plus chemotherapy
  - ESPAC-3 trial after resection: Compared with 5-fluorouracil (5-FU) and folinic acid, gemcitabine did not improve overall survival.
  - Currently, postoperative gemcitabine alone or in combination with 5-FU–based chemoradiation is the current standard of care; preoperative neoadjuvant treatment trials are in progress (1)[A].
  - Preliminary results from clinical trials indicate that outcome is better with preoperative chemoradiotherapy rather than immediate surgery in cases of borderline resectable pancreatic cancer (3).
- **Stage III**
  - Standard: 6 months of chemotherapy with gemcitabine-based regimens (1)[A]; added chemoradiation (capecitabine and radiotherapy) is controversial (1)[B].
  - FOLFIRINOX (leucovorin, fluorouracil, irinotecan, and oxaliplatin) and gemcitabine plus nab-paclitaxel were recently shown to have a benefit in patients with metastatic disease; may be tried in patients with locally advanced disease. These regimens are used for patients with no or minimal performance restrictions (1,4)[A].
  - Palliation of biliary obstruction by endoscopic, surgical, or radiologic methods
  - Intraoperative radiation therapy and/or implantation of radioactive substances
- **Stage IV**
  - Chemotherapy: Gemcitabine ± erlotinib or capecitabine may modestly prolong survival compared with gemcitabine alone. This regimen is used for patients with significant performance restrictions (1,4)[A].
  - Oxaliplatin- and irinotecan-containing regimens (including fluoropyrimidines) have similar efficacy when used after first-line gemcitabine-based therapy in stage IV patients (5)[A].
  - In gemcitabine-refractory pancreatic cancer, S-1 (a fluoropyrimidine not available in the United States) combination regimens have a higher response rate and longer progression-free survival (PFS) than oral S-1 monotherapy (6)[A].
  - Pain-relieving procedures (celiac or intrapleural block); supportive care; palliative decompression
  - Duodenal obstruction: endoscopic expandable metal stent placement rather than surgery (1) [C]
  - Biliary obstruction: Endoscopic biliary stenting is safer than percutaneous insertion and is as successful as surgical hepaticojejunostomy (1)[A].

**ADDITIONAL THERAPIES**

- For resected tumors: postoperative radiation therapy with other chemotherapeutic agents
- Intraoperative radiation therapy and/or implantation of radioactive substances (ongoing trials)
- Biliary decompression with endoprosthesis or transhepatic drainage for bile duct obstruction
- Celiac axis and intrapleural nerve blocks can provide effective pain relief for some patients.
- Opiates may be needed for pain control.

**SURGERY/OTHER PROCEDURES**
Standard treatment options
- Pancreaticoduodenectomy, Whipple procedure, en bloc resection of the head of the pancreas, distal common bile duct, duodenum, jejunum, and gastric antrum
- Total pancreatectomy
- Distal pancreatectomy for body and tail tumors

Nonstandard surgeries
- Pylorus-preserving pancreaticoduodenectomy, regional pancreatectomy
- Palliative bypass
  - Biliary decompression; gastrojejunostomy for gastric outlet obstruction; duodenal endoprosthesis for obstruction

ONGOING CARE

DIET
- Anorexia, asthenia, pain, and depression may contribute to cachexia.
- Fat malabsorption due to exocrine pancreatic insufficiency may contribute to malnutrition; pancreatic enzyme replacement may help to alleviate symptoms.
- Fat-soluble vitamin deficiency may require replacement therapy.

PROGNOSIS
- 90% diagnosed with pancreatic cancer die from the disease, predominantly from metastatic disease (2).
- 5-year survival: ~30% if node-negative; 10% if node-positive. Median survival: 10 to 20 months
- Metastatic cancer: 1–2% 5-year survival
- For localized disease and small cancers (<2 cm) with no lymph node involvement and no extension beyond the capsule, complete surgical resection can yield a 5-year survival of 18–24%.
- Detection of curable precursor lesions is a focus of current efforts to improve diagnosis and prognosis.

COMPLICATIONS
- Diabetes mellitus, malabsorption, thrombophlebitis
- Duodenal or distal bile duct obstruction
- Surgical complications: intra-abdominal abscess, postgastrectomy syndromes, pancreaticojejunostomy, gastric and biliary anastomotic leaks; operative mortality varies.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**
- C25.9 Malignant neoplasm of pancreas, unspecified
- C25.0 Malignant neoplasm of head of pancreas
- C25.1 Malignant neoplasm of body of pancreas

**CLINICAL PEARLS**

- Sudden onset of diabetes mellitus in nonobese adults aged >40 years may warrant consideration of pancreatic cancer in selected cases.
- Presence of occult peritoneal tumor cells denotes a worse survival in resectable pancreatic cancer patients.
- Diagnostic laparoscopy may decrease the rate of unnecessary laparotomy in pancreatic cancer found to be resectable on CT.
PANCREATITIS, ACUTE
Robert L. Frachtman, MD ● Marni L. Martinez, APRN

BASICS

DESCRIPTION
Acute inflammation of the pancreas with variable involvement of regional tissue or remote organ systems
- Symptoms relate to intrapancreatic activation of enzymes with pain, nausea, and vomiting, and associated intestinal ileus.
- Complete structural and functional recovery if there is no necrosis or pancreatic ductal disruption

EPIDEMIOLOGY

Incidence
1 to 5/10,000, with no predominant age or sex

Prevalence
- 19/10,000
- It is the most common gastrointestinal diagnosis for inpatient hospitalization.

ETIOLOGY AND PATHOPHYSIOLOGY

- Alcohol—most common in adults (ages 30–50)
- Gallstones (including microlithiasis)—most common in adults (median age of 69)
- Trauma/surgery—most common in adults (median age of 65)
- Acute discontinuation of medications for diabetes or hyperlipidemia
- Following endoscopic retrograde cholangiopancreatography (ERCP)
- Medications (most common, not an exhaustive list)
  - ACE inhibitors; angiotensin receptor blockers (ARBs); thiazide diuretics and furosemide
  - Antimetabolites (mercaptopurine and azathioprine)
  - Corticosteroids; glyburide; exenatide
  - Mesalamine
  - Sulfamethoxazole/trimethoprim, pentamidine
  - Valproic acid
  - Statins
- Metabolic causes
  - Hypertriglyceridemia (classically >1,000 mg/dL); even nonfasting levels as low as ~≥177 mg/dL.
  - Hypercalcemia; acute renal failure
  - Diet with high glycemic load
  - Systemic lupus erythematosus/polyarteritis/other vascular disease
  - Autoimmune; type I with elevated IgG4 and type II with normal IgG4
  - Infections: Mumps, coxsackie, CMV, EBV, cryptosporidiosis, ascaris, clonorchis
- Penetrating peptic ulcer (rare)
- AIDS
- Cystic fibrosis, CFTR gene mutations, and other mutations
- Tumors (e.g., pancreatic, ampullary)
- Miscellaneous obstruction
  - Celiac disease
  - Crohn disease
  - Pancreas divisum
  - Sphincter of Oddi dysfunction
  - Choledochocele
- Scorpion venom
- Acute fatty liver of pregnancy
- Idiopathic
- Associated coexisting risk factors
  - Obesity
  - Type II diabetes
  - Smoking
- Pathophysiology—enzymatic autodigestion of the pancreas with interstitial edema and third spacing of fluid. Possible sequelae include necrosis, pseudocyst formation, pancreatic ductal disruption, pancreatic ascites, multiorgan failure (early or late), walled off necrosis (late), and injury to surrounding vascular structures such as splenic vein thrombosis and splenic artery pseudoaneurysm.
- Cellular injury alters membrane trafficking, which alters lysosomal function leading to trypsin formation and zymogen activation. A robust inflammatory response ensues resulting in increased vascular permeability, hemorrhage, edema, and necrosis.
- The severity of the first episode of acute pancreatitis, alcohol abuse, and smoking all increase the risk of acute recurrent pancreatitis, which, in turn, increases the risk of progression to chronic pancreatitis.
- Clinical features associated with an increasing severity of acute pancreatitis: age ≥60 years; obesity; long-term, heavy alcohol use

**Genetics**
- Hereditary pancreatitis is rare; autosomal dominant
- Polymorphisms and mutations in multiple genes

**GENERAL PREVENTION**
- Avoid excess alcohol consumption.
- Tobacco cessation
- Correct underlying metabolic processes (hypertriglyceridemia or hypercalcemia).
- Discontinue offending medications.
- Cholecystectomy (symptomatic cholelithiasis)
- Diet: There is an increased risk of gallstone pancreatitis with diets high in saturated fats, cholesterol, red meat, and eggs. Decreased risk of gallstone pancreatitis with diet high in fiber and vitamin D. There is a decreased risk of nongallstone pancreatitis with diets high in fiber, coffee, and caffeine.

**COMMONLY ASSOCIATED CONDITIONS**
- Alcohol withdrawal, alcoholic hepatitis, diabetic ketoacidosis, and ascending cholangitis
- Morbid obesity, a pro-inflammatory state, increases severity and adverse outcomes (organ failure, mortality).
**DIAGNOSIS**

Symptoms don’t always correlate with objective findings.

**HISTORY**
- Acute onset of “boring” epigastric pain, which may radiate toward the back
- Nausea/vomiting
- Alcohol use
- Personal or family history of gallstones
- Medication use—look for inciting medications
- Abdominal trauma
- Recent significant rapid weight loss

**PHYSICAL EXAM**
- Vital signs—assess hemodynamic stability; fever; tachycardia; hypotension
- Abdominal findings: epigastric tenderness, loss of bowel sounds, peritoneal signs
- Other findings: jaundice, rales/percussive dullness
- Rare (with hemorrhagic pancreatitis)
  - Flank discoloration (Grey Turner sign) or umbilical discoloration (Cullen sign)

**DIFFERENTIAL DIAGNOSIS**
- Penetrating peptic ulcer
- Acute cholecystitis or cholangitis
- Macroamylasemia, macrolipasemia
- Mesenteric vascular occlusion and/or infarction
- Intestinal obstruction; perforated viscus
- Aortic aneurysm (dissecting or rupturing)
- Inferior wall myocardial infarction
- Lymphoma

**DIAGNOSTIC TESTS & INTERPRETATION**
- Interpret laboratory and radiographic findings in the context of the clinical history—false-positive and false-negative findings are common.
- Bedside Index for Severity in Acute Pancreatitis (BISAP) score
  - Patients receive 1 point for each element in the first 24 hours: BUN >25 mg/dL, impaired mental status, systemic inflammatory response syndrome (SIRS)—a score of 0 predicts mortality of <1%, and a score of 5 correlates with a mortality rate of 22%.
- Ranson criteria is an older model of predicting severity of pancreatitis. It includes 11 criteria, 5 of which are measured at admission, and 6 are measured in the following 48 hours. A score of 3 or less represents mild pancreatitis, and as the score increases, the mortality rises sharply.
- American College of Gastroenterology requires at least two of the three following elements to make a diagnosis of acute pancreatitis: characteristic abdominal pain, specific radiographic findings, and lipase level 3 times the upper limit of normal (ULN).
- Elevated serum amylase >3 times ULN (Severity is not related to degree of elevation. Amylase is not specific to pancreatitis)
- Elevated serum lipase >3 times ULN (may stay elevated longer than amylase in mild cases. Lipase is more specific to the pancreas than amylase)
Elevated total bilirubin. If >3 mg/dL, consider common bile duct obstruction.

A 3-fold elevation in the alanine aminotransferase (ALT) in the setting of acute pancreatitis has a 95% positive predictive value for gallstone pancreatitis. Triglyceride levels >1,000 mg/dL suggest hypertriglyceridemia as the cause.

Glucose and calcium increased in severe disease.

WBC elevation to 10,000 to 25,000/μL possible and not indicative of active infection

Elevated baseline hematocrit >44 or rising hematocrit is poor prognostic sign (severe third spacing with associated hemoconcentration).

Rising BUN and creatinine imply volume depletion or acute renal failure.

Elevated D-dimer is predictive of organ failure.

Initial Tests (lab, imaging)

- Use follow-up labs to assess renal function, hydration, sepsis, biliary obstruction, and tissue oxygenation.
- Chest x-ray (CXR) to evaluate for early acute respiratory distress syndrome (ARDS) and pleural effusion; can also rule out subdiaphragmatic air (perforated viscus)
- Ultrasound to look for gallbladder/biliary stones
- CT scan
  - Confirms the diagnosis, assesses severity, establishes a baseline, provides prognostic information and rules out most other pathologies (excluding noncalcified choledolithiasis)
  - IV contrast is not essential for the initial CT scan; avoid contrast in volume-depleted patients.
  - If not contraindicated, a CT scan with IV contrast on day 3 can assess the degree of necrosis if necrotizing pancreatitis is suspected.
  - The presence of gas in the peripancreatic collection is strong evidence for infection, but its absence does not rule it out.
- Magnetic resonance cholangiopancreatography (MRCP) helps assess choledocholithiasis, pancreas divisum, dilated pancreatic duct, and ductal changes.
- Esophagogastroduodenoscopy (EGD) may be necessary to rule out a penetrating duodenal ulcer or an obstructing ampullary neoplasm.
- ERCP may be necessary to decompress common bile duct due to an impacted stone.
- Endoscopic ultrasonography (EUS) is useful if patients present with “idiopathic pancreatitis.”
- EUS-guided fine needle aspiration if autoimmune pancreatitis is suspected

Follow-Up Tests & Special Considerations

If renal function is stable, a contrast-enhanced CT scan at day 3 to assess for necrosis. CT guidance assists aspiration and drainage of abscess—mainly recommended if a fungal or drug-resistant infection is suspected.

TREATMENT

GENERAL MEASURES

Most cases of acute pancreatitis require hospitalization; ICU if multiorgan dysfunction or hypotension/respiratory failure; 15–20% of cases of acute pancreatitis progress from mild to severe (including persistent organ failure).

- Fluid resuscitation
- Significant volume deficit due to third spacing
  - Infuse bolus of 500 mL/hr × 4 hours (lactated Ringer may be better than normal saline, unless hypercalcemic), with follow-up rate adjusted on the basis of age, weight, hemodynamic response, and comorbid conditions (1)[A].
  - Target urine output should be 0.5 to 1.0 mL/kg/hr. Lower the infusion rate when this goal is achieved or once BUN decreases; 4 L should be the maximum total fluid on day 1.
  - Fluid resuscitation is of limited value after 24 hours, and fluid overload results in significant complications (2)[A].

- Eliminate unnecessary medications, especially those implicated as causes of pancreatitis.
- Nasogastric (NG) tube for intractable emesis
- Follow renal function, volume status, calcium, and oxygenation. Organ failure is more important prognostic indicator than pancreatic necrosis.
- DVT prophylaxis
- Begin oral alimentation after pain, tenderness, and ileus have resolved; small amounts of high-carbohydrate, low-fat, and low-protein foods; advance as tolerated; NPO or NG tube if vomiting persists. In cases of mild pancreatitis, a soft low-fat diet may be started even before enzymes elevation and pain have completely resolved (2)[A].

- Enteral nutrition at level of ligament of Treitz if oral feeding not possible within 5 to 7 days (preferable to total parenteral nutrition [TPN] due to decreased infection rate and decreased mortality). Discontinue with increases in pain, increases in amylase/lipase levels, or fluid retention.
- TPN (without lipids if triglycerides are elevated) if oral or nasoenteric feedings are not tolerated (3)[A]

**MEDICATION**
**First Line**
- Analgesia: no consensus; guidelines vary: hydromorphone (Dilaudid) 0.5 to 1.0 mg IV q1–2h PRN
  - AVOID meperidine (Demerol) due to the potential of accumulation of a toxic metabolite.
- Antibiotics
  - In the clear absence of infection, the use of prophylactic antibiotics is no longer recommended (even with necrotizing pancreatitis).
  - In patients with ascending cholangitis or necrotizing pancreatitis, if there is a strong suspicion of active infection, consider empiric imipenem class or β-lactam/β-lactamase inhibitor (e.g., piperacillin/tazobactam 4.5 g IV q8h) for initial treatment before cultures (especially aspirates) return.
  - Levofloxacain 500 mg QD IV if cholangitis and there is an allergy to penicillin
  - Watch for fungal superinfections when giving prophylactic antibiotics.

**ISSUES FOR REFERRAL**
Refer to a tertiary center if pancreatitis is severe or actively evolving and when advanced imaging or endoscopic therapy is being considered.

**SURGERY/OTHER PROCEDURES**
- Consider cholecystectomy before discharge in patients with cholelithiasis and nonnecrotizing pancreatitis to reduce risk of recurrence.
- Necrosectomy should be performed nonsurgically for either infected or noninfected necrosis.
Walled-off necrosis should be observed for 4 weeks (treated with antibiotics if infected), followed by percutaneous or dual-modality drainage if available. Drainage may not be required if there are no signs of infection. Aspiration and culture are not required if infection is suspected and if patient is responding to appropriate antibiotic therapy (2)[A].

- ERCP early if evidence of acute cholangitis or at 72 hours if evidence of ongoing biliary obstruction; ERCP with pancreatic ductal stent placement, if ductal disruption persists longer than 1 to 2 weeks
- Resection or embolization for bleeding pseudoaneurysms
- Plasma exchange with insulin within 24 hours of presentation if severe necrotizing pancreatitis secondary to hypertriglyceridemia (4)[C]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Discharge criteria
- Pain controlled
- Tolerating oral diet
- Alcohol rehabilitation and tobacco cessation
- Low-grade fever and mild leukocytosis do not necessarily indicate infection and may take weeks to resolve. Infections may occur even after 10 days (33% of patients with necrotizing pancreatitis) due to secondary infection of necrotic material, requiring surgical debridement.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Follow-up imaging in several weeks if the original CT scan showed a fluid collection or necrosis or if the amylase/lipase continues to be elevated. Follow-up findings may include:
  - Pseudocyst (occurs in 10%) or abscess (sudden onset of fever): Conservative management is an option for asymptomatic pseudocysts up to 6 cm in diameter.
  - Splenic vein thrombosis in 16–18% with necrotizing pancreatitis
  - Pseudoaneurysm (splenic, gastroduodenal, intrapancreatic) hemorrhage can be life-threatening.
- Mild exocrine and endocrine dysfunction is usually subclinical. Patients with necrotizing pancreatitis, steatorrhea, or ductal obstruction, however, should receive enzyme supplementation.
- After the first episode of acute pancreatitis, the risk of lifetime diabetes doubles.
- After the first episode of acute pancreatitis, the risk of developing acute recurrent pancreatitis is ~17%. The risk for developing chronic pancreatitis is ~8%.

DIET
Advance diet as tolerated; reduce fat, alcohol, and added sugars.

PROGNOSIS
85–90% of cases of acute pancreatitis resolve spontaneously; 3–5% mortality (17% in necrotizing pancreatitis)

REFERENCES

ADDITIONAL READING

CODES

ICD10
- K85.9 Acute pancreatitis, unspecified
- K85.8 Other acute pancreatitis
- K85.2 Alcohol induced acute pancreatitis

CLINICAL PEARLS

- Pancreatitis is a common cause of hospitalization.
- Gallstones and alcohol misuse are the leading causes of pancreatitis.
- The BISAP score is easier to apply than Ranson criteria and just as accurate for predicting mortality in patients with acute pancreatitis.
- Review all medications and discontinue any that may cause (or contribute to) pancreatitis.
- Start oral feeding as soon as possible in the absence of severe pain, vomiting, or ileus.
- Patients with mild pancreatitis can progress to severe pancreatitis over the initial 48 hours, often due to inadequate fluid replacement.
- Refer to tertiary center if acute pancreatitis is severe or evolving/worsening.
PANIC DISORDER
Jay Winner, MD, FAAFP

BASICS

DESCRIPTION
- A classic panic attack is characterized by rapid onset of a brief period of sympathetic nervous system hyperarousal accompanied by intense fear.
- In panic disorder, multiple panic attacks occur (including at least two without a recognizable trigger). Patients experience at least 1 month of worried anticipation of additional attacks and/or maladaptive (e.g., avoidance) behaviors.

EPIDEMIOLOGY

Incidence
- Predominant age: all ages; in school-age children, panic disorder can be confused with conduct disorder and school avoidance.
- Median age of onset 24 years. Prevalence significantly decreases after 60 years.
- Predominant sex: female > male (2:1)

Prevalence
- Lifetime prevalence: 4.7%
- 4–8% of patients in a primary care practice population have panic disorder.
- Of patients presenting with chest pain in the emergency room, 25% have panic disorder.
- Chest pain is more likely due to panic if atypical, younger age, female, and known problems with anxiety.

ETIOLOGY AND PATHOPHYSIOLOGY

Remain unproven
- Biologic theories focus on limbic system malfunction in dealing with anxiety-evoking stimuli.
- Psychological theories posit deficits in managing strong emotions such as fear and anger.
- Patients resist the initial surge of adrenaline which exacerbates the symptoms—in essence, they get anxious about being anxious. Concerns about a dangerous cause of symptoms and worries about going crazy or losing control also exacerbate symptoms.
- Noradrenergic neurotransmission from the locus coeruleus causes increased sympathetic stimulation throughout the body.
- Current neurobiologic research focuses on abnormal responses to anxiety-producing stimuli in the hippocampus, amygdala, and prefrontal cortex; for example, there appears to be limbic kindling in which an original frightening experience dominates future responses even when subsequent exposures are not objectively threatening.
- Brain pH disturbances (e.g., excess lactic acid) from normal mentation in genetically vulnerable patients may activate the amygdala and generate unexpected fear responses.
- Twin studies have suggested a heritability of approximately 40% with contributions of 10% from common familial environment and >50% from individual-specific environmental effects. Some monoamine-related genes, such as serotonin transporter and monoamine oxidase A genes, have been proven to play a role in panic disorder.
RISK FACTORS
- Life stressors of any kind can precipitate attacks.
- History of sexual or physical abuse; anxious, overprotective parents
- Substance abuse, bipolar disorder, major depression, obsessive-compulsive disorder (OCD), and simple phobia

GENERAL PREVENTION
Theoretically, healthy lifestyle and education in stress reduction techniques and mindfulness are useful in prevention.

COMMONLY ASSOCIATED CONDITIONS
- Of patients with panic disorder, >70% also have ≥1 other psychiatric diagnoses: PTSD (recalled trauma precedes panic attack), social phobia (fear of scrutiny precedes panic attack), simple phobia (fear of something specific precedes panic), major depression, bipolar disorder, substance abuse, OCD, separation anxiety disorder.
- Panic disorder is more common in patients with asthma, migraine headaches, hypertension, mitral valve prolapse, reflux esophagitis, interstitial cystitis, irritable bowel syndrome, fibromyalgia, nicotine dependence.
- Panic disorder increases the risk of suicide attempts and ideation.

DIAGNOSIS
- Panic attack: an abrupt surge of intense fear, reaching a peak within minutes in which ≥4 of the following symptoms develop abruptly: (i) palpitations, pounding heart, or accelerated heart rate; (ii) sweating; (iii) trembling or shaking; (iv) sensation of shortness of breath or smothering; (v) a choking sensation; (vi) chest pain or discomfort; (vii) nausea or abdominal distress; (viii) feeling dizzy, unsteady, light-headed, or faint; (ix) derealization (feelings of unreality) or depersonalization (feeling detached from oneself); (x) fear of losing control or going crazy; (xi) fear of dying; (xii) paresthesias; (xiii) chills or hot flashes
- Panic disorder: recurrent unexpected panic attacks not better accounted for by another psychiatric condition (e.g., PTSD, OCD, separation anxiety disorder, social anxiety disorder, or specific phobia) and not induced by drugs of abuse, medical conditions, or prescribed drugs and with ≥1 month of at least one of the following: (i) worry about additional attacks or worry about the implications of the attack (e.g., losing control, having a heart attack, “going crazy”), (ii) a significant maladaptive change in behavior related to the attacks
- Panic attack specifier can be diagnosed for patients with panic attacks who do not meet the criteria for panic disorder
- Unlike DSM IV, DSM-5 defines agoraphobia as separate from panic disorder.

HISTORY
- The best way to get a good history is through tactful, nonjudgmental questioning. Information should be elicited about physical and emotional symptoms, current life stress, separations, recent deaths, patient’s concerns and fears, interpersonal problems.
- A thorough medication and substance abuse history is important.
- Patients must have a month of fear of out-of-the-blue panic attacks to diagnose panic disorder. Ask for avoidance patterns that have developed since the onset of panic attacks.
PHYSICAL EXAM

- During an attack, there can be tachycardia, hyperventilation, and diaphoresis.
- Check the thyroid for fullness or nodules. Look for exophthalmos or lid lag.
- Cardiac exam to check for a murmur or arrhythmias
- Lung exam to rule out asthma (limited airflow, wheezing)

DIFFERENTIAL DIAGNOSIS

- Medication use may mimic panic disorder and create anxiety: Paradoxically, antidepressants used to treat panic may, initially, worsen panic; antidepressants in bipolar patients can cause anxiety/mania/panic; short-acting benzodiazepines (alprazolam), β-blockers (propranolol), and short-acting opioids can cause interdose rebound anxiety; benzodiazepine treatment causes panic when patients take too much and run out of these medicines early; bupropion, levodopa, amphetamines, steroids, albuterol, sympathomimetics, fluoroquinolones, and interferon can cause panic.
- Substances withdrawal or abuse: alcohol withdrawal, benzodiazepine withdrawal, opioid withdrawal, caffeine, marijuana (panic with paranoia), amphetamine abuse, MDMA, hallucinogens (PCP, LSD), dextromethorphan abuse, synthetic cathinones (bath salts) abuse
- Medical conditions: cardiovascular (tachyarrhythmias, myocardial infarction (MI), mitral valve prolapse), pulmonary (asthma, COPD, reflux esophagitis with hyperventilation, hypoxia, pulmonary embolism), endocrine (hypo-/hyperthyroidism, premenstrual dysphoric disorder, menopause, pregnancy, hypoglycemia [in diabetes], carcinoid syndrome, pheochromocytoma, Cushing syndrome, hyperaldosteronism, Wilson disease, hyperparathyroidism), neurologic (transient ischemic attacks [TIAs], pre- and postictal states, e.g., in TLE), miscellaneous (autoimmune disease, e.g., SLE; inner ear disturbances, e.g., labyrinthitis, anaphylaxis, heavy metal poisoning), sleep apnea (when nocturnal panic attacks). Note: it is unusual to have a first panic attack after the age of 40, making it more important to consider other medical conditions for those patients.
- Psychiatric conditions that have overlapping symptomatology include mood, anxiety, and personality disorders such as major depression, bipolar disorder, PTSD, borderline personality disorder, social phobia, OCD, and generalized anxiety disorder. In PTSD, there is always a recollection or visual image that precedes the panic attack. In social phobia, fear of scrutiny precedes the panic attack. In bipolar disorder, major depression, borderline personality disorder, and particularly substance abuse, the patient often complains first of panic symptoms and anxiety and minimizes other potentially relevant symptoms and behaviors.
- Somatic symptom disorder is also an illness of multiple unexplained medical symptoms, but the presenting picture is usually one of chronic symptoms rather than the acute, dramatic onset of a panic attack. Somatic symptom disorder and panic disorder can be (and often are) diagnosed together.

DIAGNOSTIC TESTS & INTERPRETATION

Consider electrocardiogram (ECG) and pulse oximetry to rule out certain serious causes of panic; consider Holter monitoring. No specific lab tests are indicated except to rule out conditions in the differential diagnosis.
- Fingerstick blood sugar in acute setting in a diabetic patient
- Thyroid-stimulating hormone (TSH), complete metabolic panel, CBC
- If chest discomfort, do appropriate workup which could include an EKG and potentially a stress test or echocardiogram.
If nocturnal panic attacks, consider sleep study.

**Diagnostic Procedures/Other**
- If a medical cause of anxiety is strongly suspected, do the workup appropriate for that condition.
- Panic Disorder Severity Scale (PDSS) is a physician or self-administered instrument for monitoring changes in severity of symptoms and response to treatment.
  - https://www.outcometracker.org/library/PDSS.pdf

**TREATMENT**
The two options are psychotherapy and medical therapy. Studies have shown that both have comparable results and neither has advantage over the other. Combined antidepressant therapy and psychotherapy is superior to either alone during initial treatment for panic disorder [2][A]. Most effective therapy includes cognitive-behavioral therapy (CBT), mindfulness-based therapy, and exposure therapy. Psychotherapy provides long-lasting treatment, often without subsequent need for medications.

**GENERAL MEASURES**
Patient education is a vital part of treatment. This can be supplemented by video and written material. Instruct how symptoms can be caused by panic and the associated hyperventilation. Teach how resisting and pushing away the anxiety makes symptoms worse. Instead, rename the panic as an energy burst and see if they can use or at least feel the energy. Also teach patients mindful diaphragmatic breathing and to mindfully notice thoughts without believing or resisting all their thoughts. If appropriate, exposure to anxiety-provoking conditions can be coupled with relaxation exercises.

**MEDICATION**
- Medication management is indicated if psychotherapy is not successful (or not available) and may be combined with psychotherapy (particularly if symptoms are severe). It is also indicated if the patient lacks the motivation or ability to participate in psychotherapy.
- Antidepressants like selective serotonin reuptake inhibitor (SSRI), serotonin-norepinephrine reuptake inhibitor (SNRI), tricyclic antidepressant (TCA), monoamine oxidase inhibitor (MAOI), and benzodiazepines have shown efficacy in treating panic disorder.
- If medications are started, they should be maintained for at least 1 year after symptom control to reduce risk of relapse.

**First Line**
- SSRIs and SNRIs are first line given efficacy, relatively benign side effect profile, and lack of abuse potential.
  - Start a low-dose SSRI, for example, fluoxetine 5 mg, paroxetine 10 mg, sertraline 25 mg, citalopram 10 mg, and escitalopram 5 mg once daily in the morning. (If sedation occurs, this can be changed to night-time dosing. Titrate up slowly every 1 to 2 weeks to therapeutic doses over a period of 6 weeks. Side effects include irritability, diarrhea, and sexual dysfunction, with less frequent side effects such as hyponatremia and serotonin syndrome. Suicidality can be seen in young patients. When stopping SSRI, taper over few months because of risk of discontinuation syndrome [3][A]. This is more important for medications with a shorter half-
life like paroxetine compared with medications such as fluoxetine.  
- Among SNRIs, venlafaxine extended release (ER) is effective. Start at 37.5 mg/day and titrate up to 75 mg/day after 7 days (maximum dose of 225 mg/day). Taper slowly over weeks to discontinue; risk of hypertension at higher doses (4)[A]  
- Patients with associated mental disorders may benefit from a combination of SSRI and psychotherapy.

**Second Line**  
- TCAs, particularly imipramine (start 25 mg/day in the evening and increase up to 25 mg every 3 days to a maximum of 200 mg/day); slower titration and lower doses are often as effective. Imipramine is as efficacious as SSRIs in the treatment of panic disorder. TCAs are considered second line because of difficulty in dosing, more side effects, and greater risk associated with overdose compared with SSRIs (5)[A]. Screen for cardiac conduction system in patients >40 years of age with an ECG.  
- Mirtazapine can be started at 15 mg QHS and potentially increased to 30 mg QHS. Side effects of sedation and weight gain may limit use, but for people suffering from weight loss and insomnia, this medication could be helpful.  
- MAOIs like phenelzine and tranylcypromine are also efficacious compared to placebo. Avoid with serotonergic agents given risk for serotonin syndrome. There are also dietary restrictions and multiple other drug interactions that limit use of these medications.  
- Benzodiazepines like alprazolam (start at 0.25 mg TID PRN) and clonazepam (start at 0.5 mg BID PRN) are FDA-approved for panic disorder. Clonazepam has a longer half-life, less interdose anxiety, and lower abuse potential than alprazolam. Benzodiazepines are associated with sedation, dependence, increased falls, increased car accidents, and increased mortality. Therefore, in general, benzodiazepines should be used just for crisis and short-term relief of severe symptoms. Prescribing benzodiazepines to patients on opiates increases risk of overdose.

**ISSUES FOR REFERRAL**  
- Refer to a counselor who specializes in anxiety treatment, which usually consists of CBT, mindfulness-based therapy, and/or exposure therapy.  
- Consider referral to a psychiatrist for panic disorder that is comorbid with bipolar disorder, borderline personality disorder, schizophrenia, suicidality, alcohol, or substance abuse.

**ADDITIONAL THERAPIES**  
- Aerobic exercise may reduce symptoms.  
- Stress reduction classes can be helpful such as Mindfulness-Based Stress Reduction (MBSR).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**  
There is limited data supporting the use of supplements for the treatment of anxiety disorders. Kava kava should be avoided because of the risks of liver failure. A 2018 meta-analysis did show potential reduction in anxiety from omega-3 fatty acids 2 g daily with EPA <60% (would start at 1 g daily).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**  
- If certain life-threatening mimics of panic disorder have not been ruled out, such as an MI or PE, hospitalize patient to complete the evaluation.  
- If a panic disorder patient has concrete suicidal ideation, a psychiatric admission is indicated.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Full therapeutic effect of antidepressants often does not occur until 4–6 weeks of being at therapeutic dose. However, because of risk of suicidal ideation when starting antidepressants in patients 24 or younger, earlier follow-up is usually indicated in those patients (usually within 1–2 weeks).

PATIENT EDUCATION

PROGNOSIS
Panic disorder is a chronic or intermittent disease. Remission occurs in 64.5% of patients with a mean time to remission of about 5.7 months. Recurrence does occur in 21.4% in those who achieved remission. Predictors of remission are female gender, absence of ongoing stressors, and a low initial frequency of attacks.

COMPLICATIONS
- Iatrogenic benzodiazepine dependence
- Iatrogenic mania in bipolar patients treated for panic with unopposed antidepressants
- Misdiagnosis of panic in patients with difficult-to-treat psychiatric conditions

Algorithm: Anxiety

CODES
ICD10
- F41.0 Panic disorder without agoraphobia
- F40.01 Agoraphobia with panic disorder
- F43.0 Acute stress reaction

CLINICAL PEARLS
- For medically stable patients, 10 minutes of vigorous aerobic exercise at onset of a panic attack often helps patient to feel safe during an attack.
- Always evaluate a patient with panic for suicidality because patients with panic disorder are at increased risk for suicide, particularly if depressed.
BASICS

DESCRIPTION
- Parkinson disease (PD) is a progressive neurodegenerative disorder caused by loss of dopaminergic neurons in the substantia nigra pars compacta as well as other dopaminergic regions of the brain.
- Cardinal symptoms include resting tremor, rigidity, bradykinesia, and postural instability.
- Diagnosis is primarily clinical.

EPIDEMIOLOGY

Incidence
- 8 to 18.6 per 100,000 person-years
- Average age of onset: ~60 years
- Slightly more common in men than women

Prevalence
- Second most common neurodegenerative disease after Alzheimer disease
- 3.3/1,000 persons
- 0.3% of general population and 1–2% of those ≥60 years of age and up to 4% of those ≥80 years of age
- Affects approximately 1 million people in the United States and 5 million worldwide

ETIOLOGY AND PATHOPHYSIOLOGY
Dopamine depletion in the substantia nigra and the nigrostriatal pathways results in the major motor complications of PD.
- Pathologic hallmark: selective loss of dopamine-containing neurons in the pars compacta of the substantia nigra
- Loss of neurons accompanied by presence of Lewy bodies (hyaline inclusion bodies) and Lewy neuritis

Genetics
Mutations in multiple autosomal dominant and autosomal recessive genes are linked to PD/parkinsonian syndrome particularly when the age at symptom onset is <50 years. Genes investigated in PD include SNCA, Parkin, PINK1, DJ-1, and LRRK2.

RISK FACTORS
- Age and family history of PD or tremor. Weak association with exposure to toxins (herbicides and insecticides); relationship is not clear.
- Repeated head trauma and living in rural areas, drinking well water, working in a wood pulp mill
- History of smoking as well as coffee and caffeine intake may reduce risk.

COMMONLY ASSOCIATED CONDITIONS
Cognitive abnormalities, autonomic dysfunction (e.g., constipation, urinary urgency), sleep
diabetes, mental status changes (depression, psychosis, hallucinations, dementia), orthostatic hypotension, and pain

**DIAGNOSIS**
- Diagnosis is based on clinical features and response to dopaminergic therapy.
- Gold standard for diagnosis is neuropathologic exam.
- Generally, bradykinesia plus either tremor or rigidity must be present in order to make the diagnosis of idiopathic PD.

**HISTORY**
Symptoms often subtle or attributed to aging
- Decreased emotion displayed in facial features
- General motor slowing and stiffness (One or both arms do not swing with walk.)
- Resting tremor (often initially one hand)
- Speech soft/mumbling
- Falls/difficulty with balance; seen with disease progression

**PHYSICAL EXAM**
- Tremor
  - Resting tremor (4 to 6 Hz) that is often asymmetric
  - Disappears with voluntary movement
  - Frequently emerges in a hand while walking and may present as pill rolling
  - May also present in jaw, chin, lips, tongue
- Bradykinesia
- Rigidity: cogwheel (catching and releasing) or lead pipe (continuously rigid)
- Postural instability

**DIFFERENTIAL DIAGNOSIS**
- Essential tremor: Bradykinesia is not present; often symmetric and occurs mostly during action or when holding hands outstretched, nonresponsive to L-DOPA
- SWEDD: scans without evidence of dopaminergic deficit; isolated upper extremity resting and postural tremor resembling PD but failing to progress to generalized PD; no akinesia
- Dementia with Lewy bodies: characterized clinically by visual hallucinations, fluctuating cognition, and parkinsonism; dementia occurs concomitantly with or before the development of parkinsonism.
- Corticobasal degeneration: asymmetric parkinsonism, absence of tremor, no response to levodopa
- Multiple system atrophy: presents with parkinsonism and varying degrees of dysautonomia, cerebellar involvement, and pyramidal signs
- Progressive supranuclear palsy: impairment in vertical eye movements (particularly down gaze), hyperextension of neck, and early falling; pseudobulbar palsy
- Idiopathic basal ganglia calcification
- Associated neurodegenerative disorders: late stages of Alzheimer disease, Huntington disease, frontotemporal dementia, spinocerebellar ataxias
- Secondary parkinsonism:
  - Drug induced: reversible; may take weeks/months after offending medication is stopped;
often bilateral symptoms
- Neuroleptics (most common cause)
- Antiemetics (e.g., prochlorperazine and promethazine), metoclopramide
- SSRIs
- Calcium channel blockers (e.g., flunarizine and cinnarizine)
- Amiodarone
- Lithium/valproic acid
- Cholinergics
- Chemotherapeutics
- Amphotericin B
- Estrogens

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Diagnosis is mainly clinical, and there are no confirmatory physiologic or blood tests.
- Clear benefit from dopaminergic therapy is indicative of PD.
- Reduction in α-synuclein and DJ-1 protein can act as a qualitative feature in PD diagnosis.
- MRI of brain is nondiagnostic but can be used to rule out structural abnormalities.
- DaTscan: Striatal dopamine transporter imaging can distinguish PD and other parkinsonian syndromes but cannot differentiate between them.
- PET and single-photon emission CT may be helpful with diagnosis but are not required.

**TREATMENT**

**GENERAL MEASURES**

- Multidisciplinary rehabilitation with standard physical and occupational therapy components to improve functional outcomes
- Physiotherapy to help with gait reeducation, enhancement of aerobic capacity, improvement in movement initiation, improvement in functional independence, and help with home safety

**MEDICATION**

- PD goal: Improve motor and nonmotor deficits.
- Agents are chosen based on patient age and symptoms present.

**First Line**

- First-line agents in early PD: levodopa, dopamine agonists, monoamine oxidase B (MAO-B) inhibitors (1)[A]
  - Levodopa combined with carbidopa is still the most effective treatment for symptoms of PD, particularly bradykinesia.
  - Levodopa versus dopamine agonist is controversial (2)[B]:
    - Most patients eventually will develop involuntary motor fluctuations or dyskinesias with levodopa. Younger patients are more likely to develop dyskinesias. Some recommend delaying initiation of levodopa to decrease drug-induced dyskinesias early in the disease.
    - Older patients often are less able to tolerate the adverse events of dopamine agonists.
    - All patients eventually will require levodopa.
  - MAO-B inhibitors (rasagiline) should be considered as initial monotherapy; currently being
investigated for potential neuroprotective effects (2)[B]

- Carbidopa + levodopa (Carbidopa inhibits peripheral conversion of levodopa.)
  - Immediate release (Sinemet)
  - Tablets (mg): 10/100, 25/100, 25/250
  - Usual initial maintenance dose: 25/100 mg PO TID. Watch for nausea/vomiting, orthostatic hypotension, sedation, and vivid dreams.
  - Orally disintegrating (Parcopa)
  - Tablets (mg): 10/100, 25/100, 25/25
  - Sustained release (Sinemet CR):
  - Tablets (mg): 25/100, 50/200
  - Dose agents initially BID

- Carbidopa + levodopa + entacapone (Stalevo)
  - Tablets (mg): 12.5/50/200, 18.75/75/200, 25/100/200, 31.25/125/200, 37.5/150/200, 50/200/200
  - Addition of entacapone as a single agent should be initiated prior to use of this combination:
    - Once daily dose of carbidopa/levodopa has been identified, may convert to Stalevo
    - Dose of levodopa may need to be decreased with the addition of entacapone.
  - Side effects are the same, plus diarrhea and brownish orange urine.

- Dopamine-receptor agonists (nonergot): side effects: nausea, vomiting, hypotension, sedation, edema, vivid dreaming, compulsive behavior, confusion, light-headedness, and hallucinations:
  - Pramipexole (Mirapex): tablets (mg): 0.125, 0.25, 0.5, 1, 1.5
    - Start with 0.125 mg TID; gradually increase every 5 to 7 days; usual maintenance of 0.5 to 1.5 mg TID
  - CrCl 30 to 59 mL/min 0.125 mg PO BID
  - CrCl 15 to 29 mL/min 0.125 mg PO daily
  - Pramipexole ER (Mirapex ER): tablets (mg): 0.375, 0.75, 1.5, 3, 4.5; start with 0.375 PO daily.
  - Ropinirole (Requip): tablets (mg): 0.25, 0.5, 1, 2, 3, 4, 5; start with 0.25 mg TID; increase gradually to 3 to 8 mg TID.
  - Requip XL: tablets (mg): 2, 4, 6, 8, 12; start at a 2-mg dose once daily; increase in 1 to 2 weeks.

- Selective MAO-B inhibitors: side effects: insomnia, jitteriness, hallucinations; mostly found with selegiline; rasagiline similar adverse events as placebo in clinical trials. Rasagiline is metabolized via CYP1A2; caution with other medications using this enzyme system (e.g., ciprofloxacin):
  - Both agents contraindicated with meperidine and numerous other agents metabolized via CYP1A2
  - At therapeutic doses, unlikely to induce a “cheese reaction” (tyramine storm)

- Selegiline (Eldepryl)
  - Tablets: 5 mg; initiate 5 mg PO BID.
  - Orally disintegrating tablet (Zelapar): 1.25 mg; 1.25 mg PO daily for 6 weeks; increase as needed to max of 2.5 mg daily.

- Rasagiline (Azilect): tablets: 0.5 mg, 1.0 mg; initiate 0.5 to 1.0 mg daily.

**Second Line**

- Second-line agents in early PD: β-adrenergic antagonists (postural tremor), amantadine, anticholinergics (young patients with tremor); lack of good evidence for symptom control (1)
Dopamine agonists (ergot): Increased adverse event profile makes these agents nonpreferred to nonergot dopamine agonists; bromocriptine (Parlodel)

Treatment of levodopa-induced motor complications
- End of dose wearing off
  - Entacapone (with each levodopa dose) or rasagiline preferred (3)[B]
  - May also consider dopamine agonist, apomorphine, selegiline (4)[B]
- Dyskinesias: typically occur at peak dopamine level
  - Amantadine may be considered; however, its efficacy is questionable (1)[B].

Anticholinergic agents: avoided due to lack of efficacy (only useful for tremor) and increased adverse event profile, including blurred vision, confusion, constipation, dry mouth, memory difficulty, sedation, and urinary retention
- Trihexyphenidyl
  - Tablets: 2 mg, 5 mg
  - Start with 1 to 2 mg daily; increase by 2 mg every 3 to 5 days until usual dose is 6 to 10 mg in 3 to 4 divided doses.
- Benztropine (Cogentin)
  - Tablets: 0.5 mg, 1 mg, 2 mg
  - Start with 0.5 to 1.0 mg in 1 to 2 divided doses; increase by 0.5 mg every 5 to 6 days; usual dose is 1 to 2 mg/day in divided doses.

N-methyl-D-aspartic acid antagonist: exact mechanism unknown, efficacy is questionable; may be useful for dyskinesias. Side effects: confusion, dizziness, dry mouth, livedo reticularis, and hallucinations
- Amantadine (Symmetrel)
  - Tablets: 100 mg
  - Start with 100 mg BID; increase to 300 mg daily in divided doses; renally adjusted

Catechol O-methyltransferase (COMT) inhibitors: entacapone preferred due to hepatotoxicity associated with tolcapone. Adverse events include nausea and orthostatic hypotension:
- Entacapone (Comtan)
  - Tablets: 200 mg
  - 200 mg with each dose of carbidopa/levodopa; max dose 1,600 mg/day
- Tolcapone (Tasmar)
  - Tablets: 100 mg, 200 mg
  - Start 100 mg TID; max dose 600 mg/day; must be taken with carbidopa/levodopa
  - Requires LFT monitoring

Apomorphine (Apokyn): nonergot-derived dopamine agonist given SC for off episodes in advanced disease; adverse events: nausea, vomiting, dizziness, hallucinations, orthostatic hypotension, somnolence
- Only for “off” episodes with levodopa therapy
- Requires initial “test” dose (2 mg); monitor for orthostatic hypotension after initial dose; initiate an antiemetic (e.g., trimethobenzamide) 3 days prior to start and continue for 2 months. Avoid ondansetron (combination contraindicated due to profound hypotension) and dopamine antagonists, such as prochlorperazine and metoclopramide.
- Effective dose ranges from 2 to 6 mg per injection.

ISSUES FOR REFERRAL
Early specialty referral (neurology) for patients with suspected PD to receive a more thorough
clinical assessment and for treatment recommendations

**ADDITIONAL THERAPIES**
- Emotional and psychological support of patient family
- Physical therapy and endurance exercise has been shown to improve balance, muscle strength, walking speed.
- Speech therapy: may be helpful in improving speech volume and maintaining voice quality
- Nutrition should be high-fiber diet with adequate hydration and regular exercise.
- Treatment of nonmotor symptoms
  - Sildenafil to treat erectile dysfunction (5)[C]
    - Tablets: 25 mg, 50 mg, 100 mg
    - Take once daily 1 hour prior to sexual activity.
    - Caution with orthostatic hypotension; avoid with nitrates.
  - Polyethylene glycol to treat constipation (5)[C]
    - Mix 17 g in 8 oz of water once daily.
    - May titrate to one soft bowel movement per day
  - Carbidopa + levodopa to treat periodic limb movements (5)[B]

**SURGERY/OTHER PROCEDURES**
Deep brain stimulation is an effective therapeutic option for patients with motor complications refractory to best medical treatment who are healthy, have no significant comorbidities, are responsive to levodopa, and do not have depression or dementia.

**ONGOING CARE**

**DIET**
- Increase dietary fluids and fiber for constipation.
- For dysphagia, consider soft food, swallowing evaluation, and increased time for meals.
- Avoid large, high-fat meals that slow digestion and interfere with medication absorption.

**PATIENT EDUCATION**
- [www.apdaparkinson.org](http://www.apdaparkinson.org)
- [www.parkinson.org](http://www.parkinson.org)

**PROGNOSIS**
- PD is a chronic progressive disease; prognosis varies based on patient-specific symptoms.
- Increased mortality in PD; on average, survival is reduced by 5% every year of follow-up (4).

**COMPLICATIONS**
Most commonly, the result of adverse effects of medications used to treat PD

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- G20 Parkinson’s disease
- G21.9 Secondary parkinsonism, unspecified
- G31.83 Dementia with Lewy bodies

CLINICAL PEARLS

- The classic description for PD is shaky (pill-rolling tremor at rest), stiff (cogwheel rigidity), slow (bradykinesia), and stumbling (shuffling gait).
- No cure—goals are to delay disease progression and relieve symptoms.
- Emphasize the importance of exercise and movement to help preserve function.
- Pharmacotherapeutic regimens need to be individualized based on age/specific symptoms.
PARONYCHIA
Nancy V. Nguyen, DO

BASICS

DESCRIPTION

- Superficial inflammation of the lateral and posterior nail folds surrounding the fingernail or toenail
- Acute: characterized by pain, erythema, and swelling lasting less than 6 weeks; usually a bacterial infection appearing after trauma. It can progress to abscess formation.
- Chronic: characterized by swelling, tenderness, cuticle elevation, and nail dystrophy and separation lasting at least 6 weeks, or recurrent episodes of acute eponychial inflammation and drainage
- May be considered work-related among bartenders, waitresses, nurses, and others who often wash their hands.
- Usually involves one finger but drug-induced paronychia may involve multiple fingers
- Relevant anatomy: nail bed, nail plate, and perionychium
- Synonym(s): eponychia, perionychia

Pediatric Considerations

Less common in pediatric age groups. Thumb/finger-sucking is a risk factor (anaerobes and Escherichia coli may be present).

EPIDEMIOLOGY

Incidence

- One of the most common hand infections in the United States
- Predominant age: all ages
- Predominant sex: female > male

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: Staphylococcus aureus (1) most common and Streptococcus pyogenes (1); less frequently, Pseudomonas pyocyanea and Proteus vulgaris.
- Chronic: eczematous reaction with secondary Candida albicans (~95%)
- Pediatric age groups: mixed anaerobic and aerobic infections from oral flora (consider Eikenella corrodens, Fusobacterium, and Peptostreptococcus)
- A paronychial infection commonly starts in the lateral nail fold.
- Acute paronychia of the fingers is often due to trauma, and the toes is often due to ingrown toenails
- Recurrent inflammation, persistent edema, and fibrosis of nail folds cause nail folds to round up and retract, exposing nail grooves to irritants, allergens, and pathogens.
- Inflammation compromises ability of proximal nail fold to regenerate cuticle leading to decreased vascular supply. This can cause decrease efficacy of topical medications.
- Early in the course, cellulitis alone may be present.
- An abscess can form if the infection does not resolve quickly.

RISK FACTORS
Acute: direct or indirect trauma to cuticle or nail fold, manicured/sculptured nails, nail biting, thumb sucking, manipulating a hangnail
Chronic: frequent immersion of hands in water with excoriation of the lateral nail fold (e.g., chefs, bartenders, housekeepers, swimmers, dishwashers, nurses)
Predisposing conditions such as diabetes mellitus (DM) and immunosuppression
Medications such as EGFR inhibitors, systemic retinoids, chemotherapy and antiretroviral agents

GENERAL PREVENTION
Acute: Avoid trauma such as nail biting or manipulating a hangnail
Chronic: Avoid exposure to allergens and contact irritants; keep fingers/hands dry; wear rubber gloves with a cotton liner. Prevent excoriation of the skin.
Keep nails short.
Avoid manicures.
Apply moisturizer after washing hands.
Good glycemic control in diabetic patients

COMMONLY ASSOCIATED CONDITIONS
Diabetes mellitus
Eczema or atopic dermatitis
Immunosuppression

DIAGNOSIS

HISTORY
Localized pain or tenderness, swelling, and erythema of posterior or lateral nail folds
  - Acute: fairly rapid onset (2–5 days after trauma)
  - Chronic: at least 6 weeks’ duration
Previous trauma (i.e., bitten nails, ingrown nails, manicured nails)
Contact with herpes infections
Contact with allergens or irritants (frequent water immersion, latex)
Immunosuppressive therapy

PHYSICAL EXAM
Acute: red, warm, tender, tense posterior or lateral nail fold ± abscess
Chronic:
  - Initially appears as swollen, tender, boggy nail fold ± abscess
  - Later appears as retraction of nail fold and absence of adjacent healthy cuticle, thickening of nail plate with prominent transverse ridges known as Beau lines and discoloration; multiple digits typically involved
Occasional elevation of nail bed or separation of nail fold from nail plate
Fluctuance, purulence at the nail margin, or purulent drainage.
Secondary changes of nail plate, like discoloration
Suspect Pseudomonas if with green changes in nail (chloronychia).

DIFFERENTIAL DIAGNOSIS
Felon (abscess of fingertip pulp; urgent diagnosis required)
Eczema
Herpetic whitlow (similar in appearance, very painful, often associated with vesicles)
Allergic contact dermatitis (latex, acrylic)
Psoriasis (especially acute flare)
Proximal/lateral onychomycosis (nail folds not predominantly involved)
Retronychia
Pemphigus vulgaris
Acute osteomyelitis of the distal phalanx
Reiter disease
Pustular psoriasis
Dermatomyositis
Malignancy: squamous cell carcinoma of the nail, malignant melanoma, metastatic disease

**DIAGNOSTIC TESTS & INTERPRETATION**
None required unless condition is severe; resistant to treatment or if recurrence or methicillin-resistant S. aureus (MRSA) is suspected, then
- Gram stain
- Culture and sensitivity
- Potassium hydroxide wet mount plus fungal culture especially in chronic paronychia
- Drugs that may alter lab results: use of over-the-counter antimicrobials or antifungals

**Initial Tests (lab, imaging)**
Consider ultrasonography if uncertain about presence of an abscess

**Diagnostic Procedures/Other**
- Incision and drainage recommended for suppurative cases or cases not responding to conservative management or empiric antibiotics
- Tzanck testing or viral culture in suspected viral cases
- Biopsy in cases not responding to conservative management or when malignancy suspected

**TREATMENT**

**GENERAL MEASURES**
- Acute: warm compresses.soaks, elevation, splint protection if pain severe
- Abscesses should be drained
  - Consider digital block anesthesia. Then, insert nail elevator or hypodermic needle at junction of the affected nail fold and nail to facilitate drainage. If no drainage occurs, use a needle or scalpel to open skin directly above abscess.
- Antibiotics may not be necessary for successful I&D of uncomplicated infections
- Chronic: Keep fingers dry; apply moisturizing lotion after hand washing; avoid exposure to irritants; improved diabetic control

**MEDICATION**

**First Line**
- Acute (mild cases, no abscess formation):
  - Frequent soaks with warm water, Burow solution (aluminum acetate solution), vinegar (acetic acid), chlorhexidine or povidone-iodine
– Topical antibiotic cream alone or in combination with a topical steroid
– Antibiotic cream applied TID–QID after warm soak (e.g., mupirocin or gentamicin or a topical fluoroquinolone) for 5 to 10 days
– If eczematous: high potency topical steroid applied BID (e.g., betamethasone 0.05% cream) for 7 to 14 days

**Acute (no abscess formation, not responding to topical treatment). Treat for 5–7 days.**
– Dicloxacillin 250 mg QID
– Cephalexin 500 mg TID–QID

**Acute (exposure to oral flora without abscess). Treat for 7 days. Cover for Eikenella.**
– Amoxicillin-clavulanate: 875 mg/125 mg BID; pediatric, 45 mg/kg q12h (for <40 kg)
– Doxycycline 100 mg BID
– Trimethoprim/sulfamethoxazole BID
– Ciprofloxacin 500 to 750 mg BID plus clindamycin 300 to 450 mg TID–QID (pediatric, 10 mg/kg q8h), or metronidazole 500 mg TID

**Acute (suspected MRSA). Treat for 7 days.**
– Trimethoprim/sulfamethoxazole 160 mg/800 mg BID
– Doxycycline 100 mg BID
– Clindamycin 300 to 450 mg TID–QID

**Chronic**
– Topical high-potency steroids: betamethasone 0.05%; applied BID for 7 to 14 days (2)[B]
– Topical antifungal: clotrimazole or nystatin; applied topically TID for up to 30 days
– Topical calcineurin inhibitor: Tacrolimus 0.1% ointment BID for up to 21 days has been shown to be effective but is more expensive.

**For paronychia caused by antiepidermal growth factor receptor antibodies, use Doxycycline 100 mg BID.**

**For paronychia caused by oncology pharmacotherapy, treat with corticosteroid ointment and phenol chemical matricectomy. Prompt treatment enables patients to continue anticancer drug treatment without impairing their quality of life.**

**Second Line**
– Systemic antifungals (rarely needed, use if topical fails)
  – Itraconazole 200 mg for 90 days (may have longer action because it is incorporated into nail plate); pulse therapy may be useful (i.e., 200 mg BID for 7 days, repeated monthly for 2 months) (1)[C].
  – Terbinafine 250 mg/day for 6 weeks (fingernails) or 12 weeks (toenails)
  – Fluconazole 100 mg daily for 7 to 14 days
  – Ciclopirox 0.77% topical suspension BID for 2 to 4 weeks along with strict irritant avoidance (3)[B]

– Antipseudomonal drugs (e.g., ceftazidime, aminoglycosides) when pseudomonas is suspected

**ISSUES FOR REFERRAL**
Chronic: In treatment failure, consider biopsy and/or, in cases of chronic paronychia, referral for possible partial excision of the nail fold or eponychial marsupialization with or without complete nail removal or Swiss roll technique.

**ADDITIONAL THERAPIES**
Topical betaxolol 0.25% eye drops once daily on paronychia and pyogenic granuloma-like
lesions covered with bandage

**SURGERY/OTHER PROCEDURES**
- Incision and drainage of abscess, if present
- A subungual abscess or ingrown nail requires partial or complete removal of nail with phenolization of germinal matrix.
- Swiss roll technique for chronic and severe acute paronychia with runaround abscess involving both nail folds ([A]
- May also use square flap technique or en bloc excision
- Recalcitrant cases may also need nail removal.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Nail braces as a noninvasive alternative to nail extraction for patients with severe paronychia induced by EGFR inhibitors

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Acute: Postdrainage care consists of warm soaks or soaking with Burow solution or acetic acid BID–TID × 2 to 3 days unless Swiss roll technique used ([C].
- Chronic: Avoid frequent immersion, triggers, allergens, nail biting, or finger sucking.

**DIET**
If patient is diabetic, consider appropriate dietary and medication changes for better control.

**PATIENT EDUCATION**
- Avoid trimming cuticles; avoid nail trauma; and stress importance of good diabetic control and diabetic education.
- Avoid contact irritants; use rubber gloves with cotton liners to avoid exposure to excess moisture.
- Use moisturizing lotion after washing hands; do not bite nails/suck on fingers.

**PROGNOSIS**
- With adequate treatment and prevention, healing can be expected in 1 to 2 weeks.
- Chronic paronychia may respond slowly to treatment, taking weeks to months.
- If no response in chronic lesions, rarely benign or malignant neoplasm may be present and referral should be considered.

**COMPLICATIONS**
- Acute: subungual abscess
- Chronic: nail thickening, discoloration of nail, and nail loss

Onychomycosis; Retronychia

CODES

ICD10

- L03.019 Cellulitis of unspecified finger
- L03.039 Cellulitis of unspecified toe
- L03.011 Cellulitis of right finger

CLINICAL PEARLS

- Consider tetanus booster when indicated.
- Consider incision and drainage when appropriate.
- For chronic paronychia, topical steroid is first-line treatment. Consider other differentials in nonresponders (e.g., rare causes: Raynaud, metastatic cancer, psoriasis, drug toxicity).
- Consider retronychia (nail embedded into proximal nail fold) for repeated episodes of proximal paronychia or treatment failure with antibiotics and antifungals. Treatment of choice is avulsion of the nail plate. Often misdiagnosed as paronychia resulting in delay of treatment.
- For chronic non-healing lesion, consider dermatology referral.
- For non-healing ulcerative paronychia, evaluate for other skin and mucosal lesions. Can be associated with IBD, particularly ulcerative colitis.
- Consider possibility of cancer if chronic inflammatory process is unresponsive to treatment.
- Consider presence of more than one nail disease at the same time (e.g., paronychia and onychomycosis).
PAROTITIS, ACUTE AND CHRONIC
Kathy Ferrer, MD • Folami Duncan, MD

BASICS

DESCRIPTION
- Parotitis is inflammation of the parotid gland caused by infection, noninfectious systemic illnesses, mechanical obstruction, or medications.
- Can be unilateral or bilateral, acute or chronic
- The parotid gland is the largest of the salivary glands, located lateral to the masseter muscle anteriorly and extending posteriorly over the sternocleidomastoid muscle behind the angle of the mandible.
- It produces exclusively serous secretions, which lack the bacteriostatic properties of mucinous secretions, making the parotid gland more susceptible to infection than other salivary glands.
- The parotid duct, also called the Stensen duct, pierces the buccinator muscle to enter the buccal mucosa just opposite the 2nd maxillary molar.
- The branches of the 7th cranial nerve or “facial nerve” bisect the gland into lobes.
- The parotid gland contains 3 to 24 lymph nodes.

EPIDEMIOLOGY
- Viral parotitis is the most common cause of parotitis in children; exact incidence is unknown and has decreased since the advent of the mumps vaccine.
- Acute bacterial parotitis occurs more frequently in elderly patients, neonates (especially preterm infants), and postoperative patients.
- Juvenile recurrent parotitis (JRP) is the second most common inflammatory cause of parotitis in children in the United States; first episode usually occurs between the ages of 3 and 6 years.
- Chronic parotitis mainly affects adults, more often females. The average age of presentation is between 40 and 60 years.
- Chronic bilateral parotid enlargement is a common manifestation of HIV infection; for perinatally HIV-infected children, the average age of onset for parotid enlargement is 5 years.

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute viral parotitis begins as a systemic infection that localizes to the parotid gland, resulting in inflammation and swelling of the gland.
  - Mumps, or paramyxovirus, has a predilection for the parotid gland and classically has been linked to parotitis. The virus replicates in the upper respiratory tract and spreads by direct contact or airborne transmission.
  - Symptoms usually begin 16 to 18 days after infection.
- Acute bacterial parotitis results from stasis of salivary flow that allows retrograde introduction of bacterial pathogens into the gland, resulting in localized infection.
- Acute parotitis pathogens
  - Viral
    - Paramyxovirus (mumps), parainfluenza virus types 1 and 3, influenza A, coxsackievirus, Epstein-Barr virus (EBV), Human Herpesvirus (HHV6)
    - Cytomegalovirus (CMV) and adenovirus have been seen in patients with HIV.
- Bacterial
  - Staphylococcus aureus and anaerobes (oral flora) most common
  - Streptococcus pneumoniae, viridans streptococci, Escherichia coli, and Haemophilus influenzae (less common)
  - Other gram-negative rods, such as Klebsiella, Enterobacter, and Pseudomonas, can be seen in chronically ill or hospitalized patients.
  - Bartonella henselae in patients with cat exposure (rare)
- Fungal
  - Candida has been isolated in chronically ill or hospitalized patients.
  - Actinomyces in patients with a history of trauma or dental caries

- Acute, recurrent parotitis
  - JRP may be secondary to chronic inflammation; etiology is unknown, but a genetic predisposition may exist.
  - Mechanical: Repeated sialolith formation leads to ductal wall damage, fibrosis, and stricture formation.
  - Pneumoperioritis may occur when air is trapped in the ducts of the parotid gland; seen in wind instrument players, glass blowers, scuba divers, and with dental cleaning.
  - Certain medications and chronic diseases (see “Risk Factors”) predispose to chronic parotitis.
  - “Anesthesia mumps”: Possible mechanisms include transient mechanical compression of the Stensen duct by airway devices, loss of muscle tone around the Stensen orifice after neuromuscular relaxants, increased salivary secretion, and increased flexion or rotation of the head during general anesthesia.

- Chronic parotitis in HIV-infected patients can be due to presence of benign lymphoepithelial cysts, follicular hyperplasia of parotid lymph nodes, or diffuse infiltrative lymphocytosis syndrome (DILS), causing infiltration of the parotid gland by CD8 cells.
  - Parotitis may be secondary to immune reconstitution after initiation of antiretroviral therapy.

- Pediatric considerations include case reports of acute parotitis as a symptom of Kawasaki disease.

**RISK FACTORS**

- Acute viral parotitis: lack of mumps, measles, rubella (MMR) vaccination
- Acute bacterial parotitis
  - Conditions that predispose to salivary stasis, such as dehydration, debilitation, poor oral hygiene, Sjögren syndrome, cystic fibrosis, bulimia/anorexia, sialolithiasis (stones), ductal stenosis, trauma
  - Immunosuppression, HIV, chemotherapy, radiation, malnutrition, alcoholism
- Neonatal parotitis: prematurity, dehydration, low birth weight, ductal obstruction, oral trauma, structural abnormalities, immunosuppression
- JRP: dental malocclusion, congenital duct malformation, genetic factors, immunologic anomalies, disrupted enzyme activity
- Drug-induced parotitis: medications such as anticholinergics, ACE inhibitors (captopril), antihistamines, tricyclic antidepressants, antipsychotics (phenylbutazone, thioridazine, clozapine), iodine (contrast media), and L-asparaginase
- Chronic parotitis: ductal stenosis, HIV, tuberculosis, Sjögren syndrome, sarcoidosis, uremia, diabetes, gout, and atopy
GENERAL PREVENTION
- MMR vaccination with the first dose between 12 and 15 months and second dose between 4 and 6 years of age; childhood mumps vaccination does not guarantee prevention, due to possibility of waning immunity with time.
  - Students in post–high school education without documented mumps immunity should receive 2 doses of the MMR vaccine, 28 days apart.
  - Pregnant women should not receive the mumps vaccine, and pregnancy should be avoided for 4 weeks after vaccination.
- Maintain adequate hydration and good dental hygiene; smoking cessation, abstinence from alcohol, and avoidance of chronic purging

COMMONLY ASSOCIATED CONDITIONS
Mumps, HIV, Sjögren syndrome, sarcoidosis, sialolithiasis

DIAGNOSIS

HISTORY
- Acute parotitis presents with sudden-onset pain and swelling of the cheek typically extending to and obscuring the angle of the mandible.
  - Viral parotitis is usually bilateral and accompanied by a prodrome of malaise, anorexia, headaches, myalgias, arthralgias, and fever; typically, overlying skin is not warm or erythematous, and no pus is reported at the opening of Stensen duct.
  - Bacterial parotitis is typically unilateral with induration, warmth, and erythema over the affected cheek; fever is often present.
  - JRP is usually unilateral; pain and swelling resolve within 2 weeks; peak incidence occurs between 4 and 6 years with exacerbations typically remitting near onset of puberty/late adolescence; purulent exudate not typical unless superinfection occurs
  - Sialolithiasis is characterized by recurrent acute swelling and pain, exacerbated by eating; sialolithiasis affects the submandibular gland more frequently.
  - Other reported symptoms include trismus (inability to open mouth), pain exacerbated by chewing or worsened by foods that stimulate production of saliva, dry mouth with abnormal taste, difficulty with drinking/eating, anorexia, or dehydration.
- Chronic parotitis presents with recurrent or chronic nontender swelling of one or both parotid glands; can have periods of remission lasting weeks to years
  - Sjögren syndrome, sarcoidosis, HIV, tuberculosis
  - May predispose to superinfection, which would present similarly to acute parotitis

PHYSICAL EXAM
Parotitis is characterized by swelling or enlargement of the parotid gland(s) overlying the masseter muscle; may obscure the angle of the mandible or cause the ear to protrude upward and outward
- Palpation of the parotid gland is best done by using one hand to start at the attachment of the earlobe and palpating anteriorly and inferiorly along the mandibular ramus while the other hand simultaneously palpates the Stensen duct orifice inside the oral cavity.
  - Tender and bilateral suggest viral etiology, whereas tender, erythematous, warm, and unilateral suggest bacterial etiology.
– Nontender in chronic parotitis (HIV, tuberculosis, Sjögren syndrome, sarcoidosis)

- Trismus, halitosis, and dental decay may be noted.
- Pus from the Stensen duct is suggestive of bacterial parotitis or superinfection; opening of duct may appear edematous and erythematous in both bacterial and viral parotitis.
- In JRP, the Stensen duct is often enlarged, dilated, erythematous, and swollen.
- Facial nerve palsy can be seen in severe cases.

**DIFFERENTIAL DIAGNOSIS**

- Lymphoma, neoplasm, lymphangitis, cervical adenitis, otitis externa, dental abscess, odontogenic infections, Ludwig angina, and cellulitis
- Parotid swelling or enlargement typically obscures the angle of the mandible (unlike cervical adenitis).
- Involvement of the Stensen duct is unique to parotitis.

**DIAGNOSTIC TESTS & INTERPRETATION**

- History and physical exam are usually sufficient for diagnosis.
- Performing aerobic culture and Gram stain of purulent drainage from Stensen duct or aerobic and anaerobic culture from needle aspiration of gland or abscess can be helpful to identify causative organism.
  - Anaerobic culture from Stensen duct will likely contain oropharyngeal contamination; it is recommended to perform anaerobic cultures only from needle aspirate fluid.
- Acute bacterial parotitis often demonstrates an elevated white blood cell count and amylase.
- For suspected mumps, the CDC recommends collecting a buccal/oral swab for mumps RT-PCR and a blood specimen for IgM and IgG serologies. Mumps RT-PCR is best obtained from a buccal swab within 1 to 3 days of parotitis onset by massaging the parotid gland area for 30 seconds prior to collection. In areas of high vaccination rates, IgM may be falsely negative necessitating correlation with clinical symptoms. A 4-fold increase of mumps IgG antibody from acute to convalescent phase indicates infection; normal <1:20
- Consider sending EBV titers and respiratory virus PCR panel if suspected viral parotitis; CMV titers should be sent in immunocompromised patients.
- For chronic, recurrent, or nontender parotitis, obtain HIV test, PPD, SS-A/SS-B antibodies, rheumatoid factor, and antinuclear antibodies to evaluate for underlying etiology.
- Consider obtaining ultrasound or CT scan of parotid area to assess for abscess, cystic masses, tumors, ductal stenosis, or sialolithiasis if no response to initial treatment. JRP patients have diffuse microcalcifications on US.
- Ultrasound is the first-line diagnostic modality for detecting sialadenitis and has high sensitivity for identifying abscess and ductal lithiasis (1)[B].
- Consider sialography for chronic parotitis to assess the anatomy and functional integrity of the gland; can be diagnostic and therapeutic

**Diagnostic Procedures/Other**

Consider performing a biopsy or fine-needle aspiration of gland if there is suspicion for tuberculosis, Sjögren syndrome, or sarcoidosis.

**Test Interpretation**

- Findings characteristic of HIV are described in the “Etiology and Pathophysiology” section.
- Noncaseating granulomas may be seen in sarcoidosis, and caseating granulomas may be found in tuberculosis and B. henselae infections.
TREATMENT

GENERAL MEASURES
- Usually a self-limiting course that requires supportive treatment with rest, adequate hydration, analgesia, and antipyretics
  - Can stimulate glands to produce saliva by sucking on hard candies or glycerin swabs
  - Local heat and gentle massage of gland
  - For chronic presentations, encourage good dental hygiene and treat underlying etiology of parotitis.
- Patients diagnosed with mumps should be isolated with standard and droplet precautions for 5 days after onset of parotid swelling. Mumps is a nationally reportable disease.
- During a mumps outbreak, the CDC supports administration of MMR vaccine even in fully vaccinated individuals.
  - A third vaccine dose has been shown to decrease risk of mumps and improve outbreak control, especially in individuals whose second MMR was >13 years prior (2)[A].
  - Underimmunized individuals should get 2 doses of the MMR vaccine separated by at least 28 days. This will not change the disease course if the person is already infected but will help prevent future infection.

MEDICATION
- Viral parotitis: There is no evidence for the role of immunoglobulin for PEP or treatment; may initiate the below antibiotics if patient is toxic appearing or has an unclear diagnosis
- Acute bacterial parotitis
  - Outpatient management: amoxicillin/clavulanate or ciprofloxacin and clindamycin
  - Chronically ill or hospitalized: ampicillin/sulbactam or clindamycin and nafcillin; if MRSA is probable, consider vancomycin or linezolid.
- Sjögren syndrome recurrent parotitis: Pilocarpine and cevimeline can stimulate saliva production and inhibit ascending infection as well as provide symptomatic relief. Alternatively, botulism toxin injection may be a consideration in these patients because it limits production of saliva and sialectasis (3)[B].

SURGERY/OTHER PROCEDURES
- Consider needle aspiration for bacterial parotitis with abscess formation or clinical deterioration with increasing pain, erythema, and swelling not responding to medication.
- For sialolithiasis, ductal stenosis, chronic obstruction related to Sjögren syndrome, or for patients with >1 recurrences per year, consult otolaryngologist for possible sialendoscopy, duct ligation, ductoplasty, or parotidectomy (4)[B].
- Consider superficial parotidectomy for severe recurrent parotid infections in patients with underlying predisposing etiology; procedure is relatively safe with low risk for permanent facial nerve palsy
- Pediatric considerations: Sialendoscopy with steroid irrigation is effective and safe for the treatment of JRP; irrigation alone may be just as effective; performing parotid ultrasound is recommended first to differentiate JRP from ductal stones (5)[A].
- Sclerotherapy with methyl violet or tetracycline has been shown to be effective in the treatment of cysts in HIV parotitis and is also considered definitive treatment for chronic parotitis (6)[C].
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission is recommended for patients with comorbidities, systemic involvement, and inability to tolerate PO as well as neonates and patients for whom close outpatient follow-up is not feasible.
- Referral to otolaryngology is needed if salivary gland mass is seen, malignancy is suspected, or no improvement with antibiotic therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Antibiotic therapy for bacterial parotitis combined with adequate hydration should result in improvement within 48 hours; if not, patient should be re-evaluated.

DIET
- Ensure adequate fluid intake.
- Hard or sour candies to promote salivary flow

PROGNOSIS
- Viral infection in immunocompetent individuals often resolves with excellent prognosis.
- Parotid cysts found in HIV-infected patients are usually benign lymphoepithelial lesions with infrequent malignant transformation.
- Increased incidence of malignant lymphoma or lymphoepithelial carcinoma may be seen in patients with Sjögren syndrome.

COMPLICATIONS
- For mumps, potential complications include orchitis, oophoritis, mastitis, aseptic meningitis, encephalitis, pancreatitis, myocarditis, sensorineural hearing loss, and nephritis.
- Untreated bacterial parotitis can lead to local extension, abscess formation, and facial paralysis.

REFERENCES
ADDITIONAL READING

CODES

ICD10

- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis
- K11.23 Chronic sialoadenitis

CLINICAL PEARLS

- History and physical exam are usually sufficient for diagnosis (parotid swelling and tenderness with or without purulent drainage from the Stensen duct).
- In recurrent or chronic cases, consider other underlying etiologies, such as HIV.
- S. aureus and anaerobes are the most common organisms isolated in acute bacterial parotitis.
- Encouraging good oral hygiene and adequate hydration in chronically ill, debilitated, and hospitalized patients can reduce occurrence.
PARVOVIRUS B19 INFECTION
David S. Quimby, MD

**BASICS**

**DESCRIPTION**
- Human parvovirus B19 is the cause of erythema infectiosum (fifth disease, morbus quintus)
- Individuals with increased RBC turnover (sickle-cell anemia, spherocytosis, thalassemia) are more susceptible to transient aplastic crisis (TAC). In immunocompromised individuals, pure red cell aplasia may lead to transfusion-dependent anemia. In immunocompetent individuals, arthritis and arthralgias are common complications of parvovirus B19 infection.
- Systems affected: hematologic/lymphatic/immunologic, musculoskeletal, skin/exocrine, central nervous system, cardiac, renal, hepatobiliary

**Pregnancy Considerations**
Documented acute infection during pregnancy should prompt referral to maternal-fetal medicine specialist. There is 30% chance of fetal transmission with acute maternal infection. This may be higher during epidemic outbreaks. Fetal death is thought to occur in 5–10% of cases of fetal infection, with highest risk prior to 20 weeks’ gestation (1).

**EPIDEMIOLOGY**
- Parvovirus B19 infection is common in childhood, and may be asymptomatic.
- Erythema infectiosum has an extremely low mortality rate.
- Peak age for erythema infectiosum is 4 to 12 years.
- Males and females are equally affected.
- Women more likely to develop postinfectious arthritis
- No known racial predilection
- In temperate climates, infections often occur from late winter to early summer.
- Local outbreaks may occur every 2 to 5 years.
- Parvovirus B19 DNA has been isolated from human remains 6,900 years old.

**Prevalence**
Based on serologic studies, infection with parvovirus B19 is extremely common. By age 5, 2–15% of individuals in the United States and Western Europe are IgG positive. This steadily increases to 70–85% seropositivity by >40 years of age.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Discovered in 1974, Parvovirus B19 is a small (20–25 nm) nonenveloped, single-stranded DNA virus in the Erythrovirus genus of the Parvoviridae family
  - Only known parvovirus to infect humans.
- Natural host of B19 is human erythroid progenitor.
- Respiratory, transfusion-related, and vertical transmission are sources of human infection.
- Incubation period is usually 4–14 days but may rarely extend to 21 days.
- Prodromal symptoms include coryza, fever, headache, and nausea. However, infection may be asymptomatic
- Rash and joint symptoms usually occur 2–3 weeks after initial infection. These are thought to
be due to immune complex formation, and are associated with viral clearance (and decreased risk of transmission).

- Patients infected with parvovirus B19 are most contagious 5 to 10 days after exposure, well before the rash typically manifests.
- Cytotoxic infection of erythroid progenitor cells decreases RBC production.

**Genetics**

Erythrocyte P antigen–negative individuals (approximately 1 in 200,000 people) are resistant to infection.

**RISK FACTORS**

- School-related epidemic and nonimmune household contacts have a secondary attack rate of 20–50%.
- Highest secondary attack rates are for childcare providers and school personnel in contact with affected children.
- Conditions with increased RBC turnover (spherocytosis, sickle-cell anemia, thalassemia) increase the risk of transient aplastic crisis.
- Immunodeficiency (congenital, due to HIV or malignancy) increases risk of pure red cell aplasia and chronic anemia.
- As many as 40% of pregnant women are not immune; 1.5% seroconversion rate per year.

**GENERAL PREVENTION**

- Respiratory spread; hand washing, cough/sneeze hygiene, and barrier precautions.
- Droplet precautions are recommended around patients with transient aplastic crisis and in immunocompromised patients.
- Difficult to eliminate exposure because the period of maximal contagion occurs prior to the onset of the typical rash.
- No significant risk of infection based on occupational exposure if proper isolation precautions are followed. Exclusion from the workplace is neither necessary nor recommended.
- No preventive vaccine is currently available.

**COMMONLY ASSOCIATED CONDITIONS**

- Nondegenerative arthritis
  - In children, joint symptoms are uncommon and typically involve the knees and ankles (may be symmetric or asymmetric joint involvement).
  - In adults, joint symptoms are much more common, usually symmetric, usually involve the hands, with less frequent involvement of larger joints. Women are affected with joint symptoms more often than men.
  - Joint symptoms generally resolve within 3 weeks but may persist for months or years. Longer-duration symptoms are more common in women. Routine radiography is not necessary.
- Transient aplastic crisis
  - Involves patients with increased RBC turnover (sickle-cell disease, spherocytosis, thalassemia) or decreased RBC production (iron deficiency anemia).
  - Presents with fatigue, weakness, lethargy, and pallor (symptoms of anemia); may have dyspnea/shortness of breath.
  - Aplastic event may be life-threatening but is typically self-limited. Reticulocytes typically reappear in 7 to 10 days with full recovery in 2 to 3 weeks.
In children with sickle cell hemoglobinopathies and hereditary spherocytosis, fever is the most common symptom (73%); rash uncommon in these patients.

- Chronic anemia
  - Seen in immunocompromised individuals (HIV, cancer, transplant) with poor antibody response
  - Usually no clinical manifestations (fever, rash, or joint symptoms)
  - Patients may be transfusion-dependent

- Fetal/neonatal infection (1)
  - Risk of transplacental spread of virus is ~30% in infected mothers.
  - Up to 50% of infected pregnant women may be asymptomatic. Vertical transmission can still occur.
  - Check IgM and IgG levels in pregnant women with symptoms consistent with parvovirus B19 infection.
  - Test pregnant women with known exposure to individuals with acute parvovirus B19.
    - If IgG positive and IgM negative, consider immune, and no further intervention is needed.
    - If IgM and IgG negative, repeat serologic testing in several weeks to look for seroconversion.
    - If IgM positive, test further to determine if acute infection is present (false-positive result).
  - Overall fetal death may occur in 5–10% of fetal infections, can occur with or without fetal hydrops.
  - Parvovirus B19 infection may account for 8–20% of cases of nonimmune fetal hydrops.
  - Fetal bone marrow is primarily impacted. RBC survival is shortened resulting in anemia and (potentially) high-output cardiac failure. Other complications can result from fetal hypoalbuminemia, myocarditis, hepatitis, and placentitis.
  - Risk of fetal loss is highest in first trimester (19%) and decreases as pregnancy progresses (15% at 13–20 weeks and 6% after 20 weeks).
  - Intrauterine fetal red blood cell transfusion can decrease fetal loss rate if fetal hydrops is present.
  - Infants who have undergone intrauterine transfusions are at risk for delays in psychomotor development.

- Parvovirus has also been associated with a stocking-glove (2).
  - Typically in younger adults, there is symmetric painful erythema and edema of feet and hands.
  - Gradually progresses to petechiae/purpura/vesicles/bullae and then skin sloughing
  - May have no other symptoms, but can have fevers or arthralgias
  - Generally resolves in 1–3 weeks without scarring

---

**DIAGNOSIS**

**HISTORY**
- May have a prodrome of fever, coryza, pharyngitis, headache, rhinorrhea, nausea.
- Rash and arthralgias develop after these symptoms.
- Arthralgias may last for weeks or longer.

**PHYSICAL EXAM**
Typical “slapped cheek” appearance that spares the nasolabial folds.
A lacy, reticular rash on the trunk, buttocks, and limbs often follows 1 to 4 days later; may last 1 to 6 weeks.
This secondary rash may be pruritic and recurrent, and exacerbated by bathing, exercise, sun exposure, heat, or emotional stress.
B19 may manifest as painful pruritic papules and purpura on the hands and feet (glove and sock distribution).

DIFFERENTIAL DIAGNOSIS
- Rubella
- Measles
- Enteroviral disease
- Systemic lupus erythematosus
- Drug reaction
- Rheumatoid arthritis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- No need for routine lab studies in typical cases. Diagnosis is clinical, and the illness is mild and self-limiting.
- IgG and IgM serology in immunocompetent patients
- B19-specific DNA polymerase chain reaction (PCR) testing for fetal infection (via cord blood or amniotic fluid) as well as for patients with chronic infection or those who are immunocompromised
- For patients with transient aplastic crisis, anemia and reticulocytopenia are present. IgM antibodies are noted by day 3, and IgG antibodies are detectable at time of clinical recovery. PCR shows high levels of viremia.
- Pregnant women exposed to B19 require serologic testing to assess fetal risk.

Follow-Up Tests & Special Considerations
Fetal/neonatal infection (3)[C]
- To exclude congenital B19 in infants with negative B19 IgM, follow IgG serology over the 1st year of life.
- Maternal serum α-fetoprotein may be increased with hydrops fetalis.
- Serial fetal ultrasound to assess for hydrops in cases of documented acute maternal infection in the 1st trimester, looking for ascites, pericardial effusion, oligohydramnios, cardiomegaly, and placental thickening
- Weekly peak systolic velocity measurements of the middle cerebral artery by Doppler US is recommended to evaluate for heart failure, fetal anemia, and the potential need for intrauterine transfusion (>1.5 MoM).
- Cerebral MRI to assess for CNS damage in infected neonates with prolonged hydrops fetalis or hematocrit <15%

Diagnostic Procedures/Other
- Skin biopsy is usually normal but may show mild inflammation consisting of perivascular infiltrations of mononuclear cells.
- In stillbirths related to maternal B19 infection, virus can be detected in all tissues.
- In hydrops fetalis, nucleated RBCs may have intranuclear inclusion bodies.
TREATMENT

GENERAL MEASURES
- No therapy is usually needed (4)[C].
- Cessation of immunosuppressive therapy allows some patients to clear chronic infections.
- B19-associated anemia in HIV-positive patients may resolve with antiretroviral therapy and immune reconstitution.

MEDICATION

First Line
- Anti-inflammatory agents for arthritic symptoms

Second Line
- May require RBC transfusions for transient aplastic crisis
- Intravenous immunoglobulin (IVIG) for B19-related refractory anemia or PRAC, especially in immunodeficient states (5)[C]
- Intrauterine RBC transfusions reduce mortality in cases of fetal hydrops.

ISSUES FOR REFERRAL
- Acute infection during pregnancy should prompt referral to a maternal–fetal medicine specialist.
- Patients with chronic or abnormal B19 infections may benefit from consultation with immunology or infectious disease specialists.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient management is typical for erythema infectiosum.
- Inpatient management for aplastic crisis, which may require RBC transfusions
- In the inpatient setting, droplet isolation is appropriate for acute infections, transient aplastic crisis, and chronic infections in the immunocompromised.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Periodic blood counts for anemic patients until they have reticulocyte recovery

PATIENT EDUCATION
- Parvovirus B19 infection and pregnancy: http://www.cdc.gov/parvovirusB19/pregnancy.html
- Healthy Children.org Parvovirus: https://www.healthychildren.org/English/health-issues/conditions/skin/Pages/fifth-disease-parvovirus-b19.aspx
- Children with typical rash are no longer infectious and may attend childcare or school.
PROGNOSIS
- Usually self-limited
- Joint symptoms usually subside within 3 weeks, but may last months to years
- ~20% of infections result in delayed virus elimination and viremia persisting for several months to years.
- Full recovery from aplastic crisis in 2 to 3 weeks

COMPLICATIONS
Conditions associated with B19 but where causality is unconfirmed
- Hepatitis: may predispose to acute fulminant hepatic failure
- Neurologic manifestations (meningoencephalitis, peripheral nervous system manifestations, myalgic encephalomyelitis/chronic fatigue syndrome)
- Myocarditis, pericarditis
- Membranoproliferative glomerulonephritis, focal segmental glomerulosclerosis, nephrotic syndrome
- Henoch-Schönlein purpura, idiopathic thrombocytopenic purpura, vasculitis, lymphocytic histiocytosis/hemophagocytic syndrome

REFERENCES

ADDITIONAL READING
CODES

ICD10
- B34.3 Parvovirus infection, unspecified
- B08.3 Erythema infectiosum [fifth disease]

CLINICAL PEARLS
- Parvovirus B19 infection is usually a benign, self-limited illness with no long-term effects.
- Patients are no longer infectious by the time the rash of erythema infectiosum, a “slapped cheek,” appears.
- Patients with increased RBC turnover (sickle cell disease, thalassemia, spherocytosis) are at risk for transient aplastic crisis.
- Immunocompromised patients are at risk for chronic anemia, which may be transfusion-dependent.
- Documentation of acute infection in pregnant women merits maternal–fetal consultation.
**PATELLOFEMORAL PAIN SYNDROME (PFPS)**
David L. Lee, MD  Munima Nasir, MD

**BASICS**

**DESCRIPTION**
- Pain in or around the patella that increases with increased patellar loading (prolonged sitting, squatting, kneeling, or ascending/descending stairs); not attributable to other causes
- Synonyms: anterior knee or retropatellar pain syndrome, chondromalacia patella, runner’s knee
- System(s) affected: musculoskeletal

**EPIDEMIOLOGY**

**Prevalence**
- Annual prevalence of 29% in adolescents and 23% in adults (1)
- In a military population, prevalence of 12% in males and 15% in females (2)

**ETIOLOGY AND PATHOPHYSIOLOGY**

Increased patellofemoral joint loading, which is often multifactorial: (3)
- Patellar misalignment or maltracking (3)
- Abnormal anatomy (e.g., patella alta, trochlear dysplasia) (3)
- Quadriceps weakness and/or tightness (3)
- Hamstring tightness (3)
- Laxity of the patellofemoral joint or a tight lateral retinaculum (3)
- Increased hip joint internal rotation (3)

**RISK FACTORS**
- In a military population: quadriceps weakness
- In adolescents: increased hip adduction strength, although this may represent increased activity level
- Previously considered risk factors: age, height, weight, body mass index, body fat, Q angle, and hip weakness

**GENERAL PREVENTION**

Strengthening and stretching exercises, particularly hip abductors and terminal extension of the quadriceps

**COMMONLY ASSOCIATED CONDITIONS**
- Overuse
- Knee ligament injury/surgery
- Patellar tendinopathy
- Prolonged synovitis
- IT band friction syndrome

**DIAGNOSIS**
HISTORY
- An accurate history to differentiate between pain and instability (pain quality, location, swelling, giving way, locking, grinding, inciting events, overuse, and history of trauma)
- Most common symptom: diffuse anterior knee pain exacerbated during or after physical activity
- Pain with squatting, descending or ascending stairs, ambulating over uneven surfaces, or running

PHYSICAL EXAM
- Single leg squat: 80% of patients with PFPS will demonstrate pain with this maneuver.
- Palpation: In patients with pain on palpation of the patellar edges, 75% are found to have PFPS.
- Evaluate knee range of motion (ROM) and for effusion.
- Compression/patellar grind test: With patient supine, place one hand superior to the patella and push the patella inferiorly. Ask the patient to contract the quadriceps; pain upon contraction is consistent with PFPS; grinding may indicate chondromalacia of the patellofemoral joint.
- These maneuvers have low sensitivity and limited diagnostic accuracy for diagnosing PFPS.

DIFFERENTIAL DIAGNOSIS
- Prepatellar bursitis
- Patellar and quadriceps tendinitis/tendinopathy
- Chondromalacia patella
- Patellofemoral arthrosis
- Patellar subluxation and dislocation
- Knee ligamentous and meniscal pathology
- IT band syndrome
- Plica syndrome
- Osteochondral defect
- Osteochondritis dissecans
- Sinding-Larsen-Johansson syndrome
- Osgood-Schlatter disease
- Knee infection
- Neuroma or nerve entrapment
- Benign or malignant tumors
- Referred pain from hip or spine

DIAGNOSTIC TESTS & INTERPRETATION
- None indicated. In general, imaging is unnecessary and not helpful in the diagnosis of PFPS. If imaging is indicated because of severity, atypical symptoms, or persistence of symptoms despite treatment, plain films with four views of the knee are recommended to view patellar tilt and to rule out other etiologies of anterior knee pain:
  - Lateral
  - Merchant (also called sunrise)
  - Standing anteroposterior
  - Posteroanterior tunnel views
- CT can be used to grade patellar malalignment.
Radiographic findings may not correlate with symptoms.

**Follow-Up Tests & Special Considerations**
Radiographic images may be normal until late stages, when the posterior patellar surface becomes irregular and cartilage erosion is radiographically detectable.

**TREATMENT**

**GENERAL MEASURES**
- Conservative therapy is the gold standard (4)[A].
- Initial goal of therapy is to increase strength, flexibility, and ROM to enable practice of correct motion (5)[A].
- Supervised therapy should focus on hip abductors and external rotators, knee extensors, and core muscles (4)[A],(5).
- Stretching of the muscles surrounding the hip and knee, particularly proprioceptive neuromuscular facilitation stretches (4)[A].

**MEDICATION**
- Acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs) for pain management
- The evidence for oral glucosamine and chondroitin sulfate and hyaluronic acid injections is lacking and is not routinely recommended for treatment of patellofemoral pain.

**ISSUES FOR REFERRAL**
- Referral for surgery after all conservative measures fails. Surgery is rarely needed.
- Recalcitrant cases can be associated with psychosocial issues including depression and abuse. Referral to a mental health care professional may be necessary in these cases.

**ADDITIONAL THERAPIES**
- Ice packs after activity have been found to improve clinical symptoms.
- Combination therapy in addition to an exercise program with other modalities such as patellar taping or manual therapy may be beneficial (1)[A].
- Ankle and foot orthoses may offer some relief in the short term, but there is lack of strong evidence to support its use, particularly in the long term (1,4)[B].

**SURGERY/OTHER PROCEDURES**
- Exercise therapy is first line.
- For patients with a tight lateral retinaculum and lateral patellar tilt: operative realignment of the patella
- For patients with a defect in the cartilage of the patellofemoral joint, cartilage resurfacing/restoration

**ONGOING CARE**

**PATIENT EDUCATION**
- Educate patient on importance of participation and compliance in a specialized exercise program with a physical therapist.
Provide a list of physical therapy locations for the patient.

**PROGNOSIS**
- PFPS is not self-limiting and can become chronic (6).
- Patellofemoral pain for longer than 12 months is associated with long-term pain (6).
- Long-term PFPS is not associated with structural patellofemoral joint OA (6).

**REFERENCES**

**ADDITIONAL READING**

SEE ALSO
Algorithm: Knee Pain

CODES
ICD10
- M25.569 Pain in unspecified knee
- M25.561 Pain in right knee
- M25.562 Pain in left knee

CLINICAL PEARLS
- PFPS is the most common cause of anterior knee pain in active adults.
- The clinical diagnosis is made by an accurate history and physical exam.
- Well-designed exercises geared at core, hip, and lower extremity flexibility and strength are the most effective evidence-based treatments.
- PFPS is not self-limiting and needs to be treated.
**PEDICULOSIS (LICE)**

Muhammad M. Hossain, DO ● Sangili Chandran, MD, MS(ortho)

**BASICS**

**DESCRIPTION**
- A contagious parasitic infection caused by ectoparasitic blood-feeding insects (lice)
- Two species of lice infest humans:
  - *Pediculus humanus* has two subspecies: the head louse (var. *capitis*) and the body louse (var. *corporis*). Both species are 1 to 3 mm long, flat, and wingless and have three pairs of legs that attach closely behind the head.
  - *Pthirus pubis* (pubic or crab louse): resembles a sea crab and has widespread claws on the 2nd and 3rd legs
- System(s) affected: skin/exocrine
- Synonym(s): lice; crabs

**EPIDEMIOLOGY**

**Incidence**
- In the United States: 6 to 12 million new cases per year
- Predominant age
  - Head lice: most common in children 3 to 12 years of age; more common in girls than boys
  - Pubic lice: most common in adults

**Prevalence**
Head lice: 1–3% in industrialized countries

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Characteristics of lice:
  - Adult louse is dark grayish and moves quickly but does not jump or fly.
  - Eggs (nits) camouflage with the individuals’ hair color and are cemented to the base of the hair shaft (within 4 mm of the scalp).
  - Nits (empty egg casings) appear white (opalescent) and remain cemented to the hair shaft.
  - Lice feed solely on human blood by piercing the skin, injecting saliva (anticoagulant properties to allow for blood meal), and then ingesting blood.
  - Itching is a hypersensitivity reaction to the saliva of the feeding louse.
- Transmission: direct human-to-human contact
  - Head lice: direct head-to-head contact or contact with infested fomite (less likely)
  - Body lice: contact with contaminated clothing or bedding
  - Pubic lice: typically transmitted sexually (fomite transmission much less likely)

**RISK FACTORS**
- General: overcrowding and close personal contact
- Head lice
  - School-aged children, gender (girls; longer hair)
  - Sharing combs, hats (including helmets), clothing, and bed linens
  - African Americans rarely have head lice; theories include twisted hair shaft and increased
use of pomades.

- Body lice: poor hygiene, homelessness
- Pubic lice: promiscuity (very high transmission rate)

### GENERAL PREVENTION

- Environmental measures: Wash, dry-clean, or vacuum items that may have contacted infected individuals.
- Screen and treat affected household contacts.
- Head lice: Follow-up by school nurses may help to prevent recurrence and spread.
- Pubic lice: Limit the number of sexual partners (condoms do not prevent transmission nor does shaving pubic hair).
- Body lice: proper body hygiene

### COMMONLY ASSOCIATED CONDITIONS

Up to 1/3 of patients with pubic lice have at least one concomitant STI.

### DIAGNOSIS

#### HISTORY

- Pruritus is common, often worse at night.
- Often associated with “outbreak” in school settings
- Investigate contacts of infected individuals.

#### PHYSICAL EXAM

- Diagnosis is confirmed by visualization of live lice.
  - P. capitis (head lice)
    - Found most often on the back of the head and neck and behind the ears (warmer areas)
    - Eyelashes may be involved.
    - Eggs, found cemented on the base of a hair shaft, are difficult to remove.
    - Pruritus may be accompanied by local erythema and small papules.
    - May see excoriations around hairline
    - Scratching can cause inflammation and secondary bacterial infection.
    - Pyoderma and lymphadenopathy may occur in severe infestation.
  - P. corporis (body lice)
    - Poor general hygiene
    - Adult lice and nits in the seams of clothing
    - Intense pruritus involving area covered by clothing (trunk, axillae, and groin)
    - Uninfected bites present as erythematous macules, papules, and wheals.
    - Pyoderma and excoriation may be seen.
  - P. pubis (pubic lice)
    - Pubic hair is the most common site, but lice may spread to hair around anus, abdomen, axillae, chest, beard, eyebrows, and eyelashes.
    - Eggs are present at the base of hair shafts.
    - Anogenital pruritus
    - Blue macules may be seen in surrounding skin.
    - Delay in treatment may lead to development of groin infection and regional adenopathy.
DIFFERENTIAL DIAGNOSIS
- Scabies and other mite species that can cause cutaneous reactions in humans
- Dandruff and other hair debris sometimes look like head lice eggs and nits but are less adherent.

DIAGNOSTIC TESTS & INTERPRETATION
- Diagnosis is based on visualization of live louse.
- Head lice: Comb hair thoroughly with a fine-toothed louse comb (0.2 to 0.3 mm between teeth) to identify live lice (1)[C]. Wet the hair to limit static electricity, which repels lice. Simple visual inspection has same sensitivity as wet combing but is only ~25% as effective as dry combing with a metal comb (2).
- Body lice: Examine the seams of clothing to locate lice and eggs (3).
- Lice and eggs are more easily visualized with a microscope.
- In contrast to dandruff, eggs and nits cannot be removed easily from a hair shaft.

Follow-Up Tests & Special Considerations
- Empty nits remain on hair shafts for months after eradication of the live infestation. Wood lamp exam: Live nits fluoresce white and empty nits fluoresce gray.
- Pubic lice: Evaluate for concurrent STIs.

TREATMENT

GENERAL MEASURES
- Head lice: Clean items that have been in contact with the head of the infected individual within 48 hours.
- Wash all bedding, towels, clothes, headgear, combs, brushes, and hair accessories in hot water (60°C).
- Vacuum furniture and carpets.
- Seal any personal articles that cannot be washed in hot water, dry-cleaned, or vacuumed in a plastic bag and store for at least 2 weeks.
- Examine and treat household members and close contacts concurrently.
- Insecticide sprays are not necessary.
- Pubic lice: Avoid sexual activity until all partners are successfully treated.
- Nit and egg removal
  - Remove eggs within 1 cm of the scalp to prevent reinfestation.
  - After treatment with shampoo or lotion, eggs and nits remain in the scalp or pubic hair until mechanically removed. Hair conditioner facilitates nit removal.
  - Eggs and nits best removed with a fine nit comb

MEDICATION
Permethrin (over the counter [OTC]), synergized pyrethrin (OTC), spinosad (Rx), benzyl alcohol (Rx), malathion (Rx), and topical ivermectin (Rx) are all effective for head lice (1)[A],(2)[C]. Permethrin, synergized pyrethrin, and malathion are effective for pubic lice (2)[C]:
- Permethrin generally preferred because it may have residual activity for up to 3 weeks.
  However, use of newer shampoos and conditioners may reduce the residual effect (1)[C].
- Malathion and spinosad are considered second line for head lice but may not require a second
application due to ovicidal activity (1)[B],(2)[C].
- Ivermectin 0.5% lotion and benzyl alcohol 5% lotion are also effective for head lice (1,2)[C].

**First Line**
- Head and pubic lice:
  - Pyrethrum insecticides: Permethrin 1% cream rinse (Nix) or pyrethrins 0.33% with piperonyl butoxide 4% (synergized pyrethrin, Rid, Pronto) are first line unless there is proven resistance in the community.
    - Apply for 10 minutes and then wash.
    - Reapply synergized pyrethrin in 7 to 10 days (day 9 is optimal); also be necessary with permethrin, if live lice are observed
    - Side effects: application-site erythema, ocular erythema, and application-site irritation
- Body lice: best treated with synergized pyrethrin lotion applied once and left on for several hours
- Eyelash infestation: Apply petroleum jelly BID for 10 days.
- Precautions:
  - Pyrethrin: Avoid in patients with ragweed allergy (may cause respiratory symptoms).
  - Pediculicides should never be used to treat eyelash infections.

**Second Line**
- Head lice and pubic lice
  - Malathion 0.5% lotion (Ovide)
    - Apply for 8 to 12 hours and then wash off.
    - Excipients isopropyl alcohol (78%) and terpineol (12%) may contribute to its efficacy:
      - Flammable and has a bad odor
      - Despite ovicidal activity, a second application may be necessary after 7 to 10 days (day 9 is optimal) if live lice are observed.
  - Lindane 1% shampoo, no longer recommended
    - Apply for 4 minutes and then wash (do not repeat).
    - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
    - Contraindications: uncontrolled seizure disorder, premature infants
    - Precautions: Do not use on excoriated skin, in immunocompromised patients, conditions that increase seizure risk, or with medications that decrease seizure threshold.
    - Possible interactions: concomitant use with medications that lower the seizure threshold
- Head lice
  - Spinosad 0.9% lotion (Natroba)
    - Apply to dry hair and scalp for 10 minutes and then rinse with warm water. Repeat in 7 days if live lice are observed.
    - Side effects: application-site erythema, ocular erythema, and application-site irritation
  - Benzyl alcohol 5% lotion (Ulesfia)
    - Apply to dry hair using enough to saturate scalp and hair (amount depends on hair length), rinse after 10 minutes; repeat in 1 week.
    - Side effects: pruritus, erythema, pyoderma, ocular irritation, application-site irritation
  - Ivermectin 0.5% lotion (Sklice)
    - Apply to dry hair by using enough to saturate the scalp and hair (max. 4 oz) and then rinse after 10 minutes.
    - Side effects: burning sensation at application site, dandruff, dry skin, eye irritation
Mechanical removal of lice and nits by wetting hair and then systematically combing with a fine-toothed comb every 3 to 4 days for 2 weeks to remove all lice as they hatch

**ALERT**
Lindane: FDA black box warning of severe neurologic toxicity (use only when first-line agents have failed). The National Pediculosis Association strongly advises against using lindane at all.

**Pediatric Considerations**
- Avoid synergized pyrethrin and permethrin in infants <2 months of age. Avoid benzyl alcohol, topical ivermectin, and spinosad in children <6 months of age and avoid malathion in children <2 years of age.
- Lindane: not recommended

**Pregnancy Considerations**
Permethrin, synergized pyrethrin, malathion, spinosad, and benzyl alcohol are pregnancy Category B. Lindane and topical ivermectin are pregnancy Category C.

**ADDITIONAL THERAPIES**
- For “difficult to treat” cases of head lice, oral ivermectin 400 μg/kg (not approved by the FDA for lice), given twice at a 7-day interval, is superior to topical 0.5% malathion lotion (4,5)[B].
- Ivermectin: 200 μg/kg PO repeated after 10 days or 300 μg/kg PO repeated after 7 days
  - Should not be used in children <15 kg; pregnancy Category C
  - Not approved by the FDA for lice
- Dual therapy with permethrin 1% and oral trimethoprim/sulfamethoxazole (TMP/SMX) only for cases of multiple treatment failures or suspected cases of lice-related resistance to therapy (TMP/SMX is not approved by the FDA for lice)
- Permethrin 5% cream (Rx) is not FDA-approved for lice and is unlikely to be effective for lice that are resistant to 1% cream rinse (1)[B].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Cetaphil lotion: dry-on, suffocation-based pediculicide (not approved by the FDA for lice)
  - Apply thoroughly to hair, comb, and then dry with hair dryer; shampoo after 8 hours.
  - Repeat once a week until cured, up to a maximum of three applications.
- Dimethicone 4% lotion: Apply to hair for 8 hours; repeat in 1 week (not approved by the FDA for lice).
- No home remedies (e.g., vinegar, isopropyl alcohol, olive oil, ylang ylang oil, mayonnaise, melted butter, and petroleum jelly) are proven as effective.
- Herbal shampoos and pomades have not been evaluated in clinical trials.
- Lavender oil and tea tree oil have been implicated in triggering prepubertal gynecomastia in boys and should not be used to treat lice.
- Electronic louse combs have not proven effective and are not approved by the FDA.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Children may return to school after completing topical treatment, even if nits remain in place. No-nit policies are unnecessary.
Patient Monitoring
Drug resistance should be suspected if no dead lice are observed 8 to 12 hours after treatment.

PATIENT EDUCATION
- National Pediculosis Association: http://www.headlice.org/
- CDC: https://www.cdc.gov/parasites/lice/

PROGNOSIS
- With appropriate treatment, >90% cure rate
- Recurrence is common, mainly from reinfection or treatment nonadherence. Resistance to synthetic pyrethroids is increasing.

COMPLICATIONS
- Poor sleep due to pruritus
- Persistent itching may be caused by too frequent use of the pediculicide.
- Missed school; social stigma
- Secondary bacterial infections
- Body lice can transmit typhus and trench fever.

ADDITIONAL READING

SEE ALSO
Arthropod Bites and Stings; Scabies
CODES

ICD10
- B85.0 Pediculosis due to Pediculus humanus capitis
- B85.1 Pediculosis due to Pediculus humanus corporis
- B85.3 Phthiriasis

CLINICAL PEARLS

- School-based no-nit policies are not necessary because empty nits may remain on hair shafts for months after successful eradication.
- Improper product application is a common cause of treatment failure.
- Prevalence of resistant infestations is increasing; if no dead lice are observed 8 to 12 hours after treatment, suspect resistance and use an alternative agent.
- Routine retreatment on day 9 is recommended for nonovicidal products (permethrin and synergized pyrethrin).
- With all treatment options, reinspect hair after 7 to 9 days, and if live lice are detected, repeat treatment on day 9.
PELVIC INFLAMMATORY DISEASE
Juliana Zamora Cubillos, MD • Miguel A. Palacios, MD

BASICS
DESCRIPTION
- Pelvic inflammatory disease (PID) is an infectious and inflammatory disorder of the upper female genital tract, including the uterus, fallopian tubes, ovaries, and adjacent pelvic structures. It is community acquired from sexually transmitted organisms (1).
- Salpingitis is the most important component due to its impact on future fertility.
- Mild to moderate PID is defined as the absence of a tubo-ovarian abscess (TOA). Severe disease is defined as severe systemic symptoms or the presence of a TOA (2).
- Diagnosis may be challenging due to variation in signs and symptoms because many patients with PID have subtle or nonspecific symptoms (3).

EPIDEMIOLOGY
- Predominant age: 15 to 25 years; This number has remained constant since early 1900s.
- Predominant sex: female only

Incidence
PID is the most common gynecologic reason for admission in the United States accounting for 18 per 10,000 recorded hospital discharges (2). The estimated prevalence of self-reported lifetime PID was 4.4% in sexually experienced women ages 18 to 44 years (4).
- Lifetime prevalence has decreased steadily since 1995 across all races (4).
- Among those with no history of prior STI, lifetime PID prevalence was higher in black versus white women (6% vs. 2.7%). Among women with a prior sexually transmitted infection (STI), lifetime prevalence of PID was similar by race (10% vs. 10.3%) (4).

ETIOLOGY AND PATHOPHYSIOLOGY
Multiple organisms may be etiologic agents in PID. Most cases are polymicrobial. The proportion of PID cases due to Chlamydia trachomatis and Neisseria gonorrhoeae appears to be declining. Fewer than 50% of women diagnosed with acute PID have a test positive for either of these organisms.
- C. trachomatis, N. gonorrhoeae, genital tract mycoplasmas (particularly Mycoplasma genitalium), aerobic and anaerobic (Bacteroides fragilis), and vaginal flora (e.g., Prevotella, peptostreptococci, Gardnerella vaginalis, Escherichia coli, Haemophilus influenzae) are recognized as etiologic agents. Mixed infections are common (1,5,6).
- Many nongonococcal, nonchlamydial microorganisms recovered from upper genital tract in acute PID are associated with bacterial vaginosis.
- The precise mechanism by which microorganisms ascend from the lower genital tract is unclear. Possible mechanisms include the following: (i) travel from cervix to endometrium to salpinx to peritoneal cavity; (ii) lymphatic spread via infection of the parametrium (from an IUD); and (iii) hematogenous route, although this is rare.
- Of cases, 75% occur within 7 days of menses, when cervical mucus favors ascent of organisms.
RISK FACTORS
- Sexually active and age <25 years
- First sexual activity at young age (<15 years)
- New/multiple sexual partners
- Nonbarrier contraceptive methods (i.e., oral contraceptive pills)
- Previous history of PID; 20–25% will have a recurrence.
- Cervical ectopy
- History of C. trachomatis; 10–40% will develop PID.
- History of gonococcal cervicitis; 10–20% will develop PID.
- Gynecologic procedures that break the cervical barrier such as endometrial biopsy, curettage, hysterosalpingography, hysteroscopy, in vitro fertilization (IVF), and insertion of IUD in the last 6 weeks

GENERAL PREVENTION
- Educational programs about safer sex practices such as barrier contraceptives, especially condoms and spermicidal creams or sponges, provide some protection.
- The U.S. Preventive Services Task Force recommends screening for chlamydia in all sexually active women <25 years and in those 25 years and older at increased risk (new sex partner/multiple sex partners). Moderate-quality evidence suggests that chlamydia screening reduces cases of PID (3)[A].
- Routine STI screening in pregnancy
- Early medical care with occurrence of genital lesions or abnormal discharge

COMMONLY ASSOCIATED CONDITIONS
- If PID is suspected in a patient with an IUD and a pelvic abscess is present, an Actinomyces infection requiring penicillin treatment may be present.
- Rupture of an adnexal abscess is rare but life threatening. Early surgical exploration is mandatory (5).
- Chlamydial or gonococcal perihepatitis may occur with PID. This combination is called Fitz-Hugh-Curtis (FHC) syndrome and is characterized by severe pleuritic right upper quadrant pain. FHC syndrome complicates 10% of PID cases.
- Plasma cell endometritis has also been seen in the majority of females with PID; the density of plasma cell infiltration has been related to severity of symptoms (5).

DIAGNOSIS
- The diagnosis of PID is based primarily on clinical evaluation.
- The positive predictive value of clinical diagnosis is 65–90% compared with laparoscopy (2).
- The CDC recommends empiric treatment for PID in sexually active females or other females at risk with pelvic or lower abdominal pain with no other cause identified and if one or more of the following is present:
  - Cervical motion tenderness
  - Uterine tenderness
  - Adnexal tenderness
- Additional criteria used to enhance specificity: fever >101°F, new/abnormal cervical mucopurulent discharge or cervical friability, presence of abundant numbers of white blood
cells (WBC) on wet prep, elevated C-reactive protein (CRP), elevated erythrocyte sedimentation rate (ESR), and laboratory documentation of cervical infection with N. gonorrhoeae or C. trachomatis (1,7)

- Most specific criteria for diagnosing PID: Endometrial biopsy reveals endometritis, transvaginal ultrasound (US) showing thickened, fluid-filled salpinges, and laparoscopic abnormalities consistent with PID (1,3).

**HISTORY**

- Lower abdominal or pelvic pain: typically described as dull, aching or crampy, bilateral, and constant; accentuated by motion, exercise, or coitus
- New/abnormal vaginal discharge (~75% of cases)
- Fever, chills, cramping, dyspareunia
- Low back pain
- Urinary discomfort
- Unanticipated vaginal bleeding, often postcoital, is reported in about 40% of cases.
- Recent hysterosalpingogram (HSG)
- IUD insertion within the past 21 days (1)

**PHYSICAL EXAM**

- Fever
- Lower abdominal pain and particularly cervical motion tenderness
- Findings of cervicitis with/without vaginal discharge (1)

**DIFFERENTIAL DIAGNOSIS**

- Appendicitis
- Constipation
- Gastroenteritis
- Ectopic pregnancy
- Ovarian tumor/torsion
- Hemorrhagic/ruptured ovarian cyst
- Endometriosis/dysmenorrhea
- Functional pelvic pain
- Inflammatory bowel disease
- Diverticulitis
- Urinary tract infection/pyelonephritis
- Nephrolithiasis (1)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Pregnancy test must be performed to rule out ectopic pregnancy and complications of an intrauterine pregnancy.
- Specific testing for chlamydia and gonorrhea (usually nucleic acid amplification test [NAAT] and/or ligase chain reaction); negative results do not exclude PID.
- Urinalysis
- Saline microscopy of vaginal fluid (for WBC)
- Consider CBC: WBC count ≥10,500/mm³, although ≤50% of PID cases present with leukocytosis.
- CRP (optional) is nonspecific and often normal in mild/moderate PID.
- Consider transvaginal US not necessary for diagnosis; may show thickened, fluid-filled tubes (hydrosalpinges) ± free fluid, or TOA.

**Pediatric Considerations**
- ESR >15 mm/hr or elevated CRP used in some diagnostic criteria
- Consider HIV testing in patients with PID.
- Follow-up ultrasound as outpatient for resolution of adnexal abscess

**Diagnostic Procedures/Other**
- Culdocentesis with culture is rarely necessary.
- Laparoscopy is best used for confirming, as opposed to making, the diagnosis of PID and should be reserved for the following situations:
  - Ill patient with competing diagnosis (e.g., appendicitis)
  - Ill patient who has failed outpatient treatment
  - Any patient not improving after 72 hours of inpatient treatment
- Endometrial biopsy (rarely indicated): reveals endometritis/plasma cells (5)

**TREATMENT**
- Patient education: Avoid unprotected intercourse until patient and partner(s) have been treated and emphasize the long-term implications for their/partner(s) health.
- Outpatient treatment, if appropriate
- Criteria for hospitalization and parenteral treatment are described below.

**GENERAL MEASURES**
- IUD removal is not required for mild PID.
- Treatment should cover principal pathogens, regardless of the test results.

**MEDICATION**

**First Line**
- Several antibiotic regimens are highly effective, with no single regimen of choice (5)[A].
- Outpatient treatment regimen
  - ceftriaxone 250 mg IM single dose plus
  - doxycycline 100 mg PO BID for 14 days
- The addition of metronidazole 500 mg PO BID for 14 days should be considered where risk of infection with anaerobic organisms is considered high, like in pelvic abscess, trichomonas vaginalis infection, bacterial vaginosis, or recent gynecologic instrumentation. Also, clindamycin 450 mg PO every 6 hours can be considered as an alternative to metronidazole.
- On the basis of the recent emergence of fluoroquinolone-resistant gonococci, the Centers for Disease Control and Prevention (CDC) no longer recommends the use of fluoroquinolones for the treatment of gonococcal infections and associated conditions such as PID.

**Second Line**
- Because of emerging resistance in gonococci, resistance testing and confirmation of treatment success is advisable (5).
- Outpatient treatment regimen
Cefoxitin 2 g IM single dose and probenecid 1 g PO, or cefotaxime (1 g IM) or ceftizoxime (1 g IM) administered concurrently in single dose plus doxycycline 100 mg PO BID for 14 days ± metronidazole 500 mg PO BID for 14 days

- In persons with documented severe allergic reactions to penicillin or cephalosporins:
  - Azithromycin PO 2 g once or spectinomycin might be an option for therapy of uncomplicated gonococcal infections.

Special consideration
- Refer sex partners for appropriate evaluation and treatment if they had sexual contact with patient during preceding 60 days or most recent sexual contact. Partners should be treated with regimens effective against chlamydia and gonorrhea (5).
- HIV-infected women with acute PID should be treated similar to non–HIV-infected women (6).

SURGERY/OTHER PROCEDURES
Reserved for failures of medical treatment and for suspected ruptured adnexal abscess with resulting acute surgical abdomen

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Criteria for hospitalization if any of following (5)[C]:
  - Surgical emergencies (e.g., appendicitis) cannot be excluded.
  - Patient is pregnant.
  - Patient does not respond clinically within 72 hours of initiation with oral antimicrobial therapy.
  - Failure to either tolerate or respond to outpatient therapy; the patient has severe illness, nausea and vomiting, or high fever, or the patient has a TOA.

- For inpatient treatment of PID, the CDC recommends following treatment regimens (7):
  - Parenteral regimen A
    o Cefotetan 2 g IV every 12 hours or cefoxitin 2 g IV q6h + doxycycline 100 mg PO or IV every 12 hours
    o Parenteral therapy for 24 hours after clinical improvement. Doxycycline should be preferred orally when possible as oral and IV provides similar bioavailability. Continue doxycycline for a total of 14 days (3).
  - Parenteral regimen B
    o Clindamycin 900 mg IV every 8 hours plus gentamicin loading dose IV or IM (2 mg/kg of body weight) followed by a maintenance dose (1.5 mg/kg) q8h or single daily dosing at 3 to 5 mg/kg can be substituted (3).
    o Parenteral therapy may be discontinued 24 hours after clinical improvement, and oral therapy with doxycycline as aforementioned or clindamycin 450 mg PO QID for a total of 14 days should be continued.
  - Parenteral regimen C
    o Ampicillin/sulbactam 3 g IV every 6 hours plus doxycycline 100 mg PO or IV every 12 hours

- PID is rare in pregnant patients, however, may appear prior to 12 weeks’ gestation before mucous plug appears. Change doxycycline to azithromycin + 2nd-generation cephalosporin (7).
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow up in 72 hours after initiation of treatment is recommended particularly for patients with moderate or severe clinical presentation (3).
- Observe for clinical signs and symptoms particularly for fever, leukocytosis, and abdominal and cervical motion tenderness.
- Retest for gonorrhea and chlamydia in 3 to 6 months. The likelihood of reinfection is high.
- Follow adnexal abscess size and position with serial USs.

PATIENT EDUCATION
- Abstinence from any type of sexual contact until treatment of patient/partner (if necessary) is complete
- Consistent and correct condom use should be enforced.
- Hepatitis B and human papilloma virus (HPV) vaccines should be given to patients who meet criteria.
- Advise comprehensive STI screening (7).

PROGNOSIS
- PID has a high morbidity; about 20% of affected women become infertile, 40% develop chronic pelvic pain, and 1% of those who conceive have an ectopic pregnancy (1).
- Wide variation with good prognosis if early effective therapy is instituted and further infection is avoided
- Poor prognosis related to late therapy and continued high-risk sexual behavior
- Nongonococcal, nonchlamydial PID is more often associated with severe PID and with worse prognosis for future fertility.

COMPLICATIONS
- TOA will develop in ~7–16% of patients with PID.
- Recurrent infection occurs in 20–25% of patients.
- Risk of ectopic pregnancy is increased 7- to 10-fold among women with a history of PID.
- Tubal infertility occurs in 8%, 19.5%, and 40% of women after 1, 2, and 3 episodes of PID, respectively.
- Chronic pelvic pain occurs in 20% of cases and is related to adhesion formation, chronic salpingitis, or recurrent infection (1,4).
- Hydrosalpinx: After PID resolves, fallopian tube may fill with sterile fluid and become blocked; it may be associated with pain and infertility related to negative outcomes with IVF.

REFERENCES

CODES

ICD10
- N73.9 Female pelvic inflammatory disease, unspecified
- N73.0 Acute parametritis and pelvic cellulitis
- N70.93 Salpingitis and oophoritis, unspecified

CLINICAL PEARLS
- Most often, PID starts with gonorrhea or chlamydia infection, but it is often polymicrobial.
- Physicians should treat on the basis of clinical judgment (pelvic pain with cervical motion tenderness or adnexal tenderness or uterine tenderness in a patient at risk) without waiting for confirmation from laboratory or imaging tests. PID is a common cause of infertility.
- Complications include hydrosalpinx, adhesions, pelvic pain, and 10-fold increased risk of ectopic pregnancy.
- Three major predictors of preserved post-PID fertility: (i) short duration of symptoms (<72 hours) prior to initiation of treatment, (ii) first episode of PID, and (iii) nongonococcal PID
PEPTIC ULCER DISEASE
Apaar Dadlani, MD, MBBS ● Thomas L. Abell, MD

BASICS
Peptic ulcer disease (PUD) is characterized by defects in the stomach and/or duodenal mucosa, leading to inflammation of the underlying tissue by gastric acid and pepsin.

DESCRIPTION
- Duodenal ulcer
  - Most common form of peptic ulcer
  - Usually located in the proximal duodenum
  - Multiple ulcers or ulcers distal to the second portion of duodenum and/or jejunum raise possibility of gastrinoma (Zollinger-Ellison syndrome).
- Gastric ulcer
  - Less common than duodenal ulcer in absence of NSAID use
  - Commonly located along lesser curvature of the antrum
- Esophageal ulcers
  - Located in the distal esophagus; usually secondary to gastroesophageal reflux disease (GERD); also seen with gastrinoma
- Ectopic gastric mucosal ulceration
  - May develop with Meckel diverticulum

EPIDEMIOLOGY
Incidence
- Predominant sex: male = female
- Predominant age
  - 70% of ulcers occur between ages 25 and 64 years.
  - Duodenal/gastric ulcer incidence increases with age.
- Peptic ulcer: 500,000 new cases per year
- Recurrence: 4 million per year
- Global incidence rate: 0.1–0.19%

Prevalence
- <10% in the general population
- The lifetime prevalence is higher in Helicobacter pylori–positive patients (10–20%) compared to the general population (5–10%).
- The incidence and prevalence of peptic ulcer disease have decreased in high-income countries including the United States (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Genetics
Increased incidence of PUD in families is likely due to familial clustering of H. pylori infection and inherited genetic factors reflecting response to the organism.

RISK FACTORS
• H. pylori infection (95% of duodenal and 70% of gastric ulcers)
• Chronic use of NSAIDs, including aspirin and COX-2 inhibitors. People who take NSAIDs regularly have been found to have concomitant H. pylori infection.
• Tobacco use
• Stress (such as acute illness, ventilator support, extensive burns, head injury)
• Hypersecretion syndromes: gastrinoma (Zollinger-Ellison), systemic mastocytosis, carcinoid syndrome
• Alcohol use
• Medications: corticosteroids (high-dose and/or prolonged therapy), bisphosphonates, potassium chloride, clopidogrel, sirolimus chemotherapeutic agents
• Radiation therapy

GENERAL PREVENTION
• NSAID ulcers: Discontinue NSAIDs and use acetaminophen instead when appropriate, or add a proton pump inhibitor [PPI] in patients with previous NSAID-related ulcer.
  – If NSAIDs are absolutely necessary, use lowest possible dose and use in combination with a PPI or misoprostol.
  – To reduce ulcer risk, consider testing for and eradicating H. pylori.
• Maintenance therapy with PPIs or H2 blockers is indicated for patients with a history of ulcer complications, recurrences, refractory ulcers, or persistent H. pylori infection.
• Consider maintenance PPI treatment in patients with H. pylori-negative, non–NSAID-induced ulcer.
  – H. pylori infection: present in 95% of duodenal and 70% of gastric ulcers; annual risk of duodenal ulcer in those with H. pylori infection: ≤1%

COMMONLY ASSOCIATED CONDITIONS
• Gastrinoma (Zollinger-Ellison syndrome)
• Multiple endocrine neoplasia type 1
• Carcinoid syndrome
• Chronic illness: Crohn disease, chronic obstructive pulmonary disease (COPD), chronic renal failure, hepatic cirrhosis, cystic fibrosis
• Hematopoietic disorders (rare): systemic mastocytosis, myeloproliferative disease, hyperparathyroidism, polycythemia rubra vera

DIAGNOSIS

HISTORY
• Signs and symptoms:
  – Duodenal ulcer
    o Midepigastric pain
    o Gnawing or burning, nonradiating, recurring pain that is often episodic
    o Relieved by food or antacids
  – Gastric ulcer
    o Midepigastric pain
    o Gnawing or burning, nonradiating, recurring pain that is often episodic
    o Aggravated by food, relieved by antacids
- Nonspecific dyspeptic symptoms: indigestion, nausea, vomiting, loss of appetite, heartburn, and epigastric fullness
- Red flag or alarm symptoms
  - Onset of symptoms after age 55 years
  - Progressive dysphagia
  - Blood in stool, melena, hematemesis, anemia
  - Persistent or recurrent vomiting
  - Severe abdominal pain
  - Weight loss, anorexia, or family history of gastric malignancy
- NSAID-induced ulcers are often silent; perforation or bleeding may be the initial presentation.

**PHYSICAL EXAM**
Physical exam for uncomplicated peptic ulcer may be nonspecific: Check vital signs for hemodynamic stability, conjunctival pallor (anemia); epigastric tenderness (absent in at least 30% of older patients); guaiac-positive stool from occult blood loss

**DIFFERENTIAL DIAGNOSIS**
Functional dyspepsia, gastritis, GERD, biliary colic, gastroenteritis, pancreatitis, cholecystitis, Crohn disease, intestinal ischemia, cardiac ischemia, gastrointestinal malignancy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Lab tests to consider:
  - Complete blood count: Rule out anemia.
  - Fecal occult blood test
  - Liver function tests
  - Lipase
  - H. Pylori testing
  - If multiple/refractory ulcers: Consider fasting serum gastrin to rule out gastrinoma.
- Indications for H. pylori testing: new-onset PUD, prior history of PUD, persistent symptoms after empiric antisecretory therapy, gastric mucosa-associated lymphoid tissue (MALT) lymphoma, noninvestigated dyspepsia in patients <50 years of age without alarm symptoms.
- H. pylori diagnostic tests:
  - False-negative results may occur if patient was recently treated with antibiotics, bismuth, or PPIs, or in patients with active bleeding.
  - Noninvasive tests:
    - Stop antibiotics and bismuth for at least 4 weeks and PPIs for 1 week prior to testing because of high false-negative rates.
    - Stool antigen: identifies active infection; can be used for screening and posttreatment testing; high positive and negative predictive value (sensitivity, 87%; specificity, 70%); patients might not want to collect stool.
    - Urea breath test: identifies active infection; can be used for screening and posttreatment testing; high positive and negative predictive value (sensitivity, 93%; specificity, 92%); variable availability and reimbursement
    - Serology: inexpensive; can be used only in untreated patients and cannot be used to document successful eradication (sensitivity, 88%; specificity, 69%)
  - Invasive tests:
- **Rapid urease test:** conducted on gastric biopsies (sensitivity, 93–97%; specificity, 95%)
- **Barium or Gastrografin contrast radiography (double-contrast hypotonic duodenography):** indicated when endoscopy is unsuitable or not feasible

**Diagnostic Procedures/Other**
- Upper endoscopy (sensitivity, >95%; specificity, >95%) is most accurate for diagnosing PUD and active H. pylori infection. Endoscopy is costly, invasive, and recommended only for patients with “red flag” symptoms (1)[B].
- **Rapid urease test:** conducted on gastric biopsies (sensitivity, 93–97%; specificity, 95%)

---

**TREATMENT**

**MEDICATION**

**First Line**
- **Acid suppression**
  - PPIs have higher efficacy than H$_2$ blockers. 95% of duodenal ulcers heal on PPI therapy within 4 weeks.
  - Omeprazole 20 mg/day PO; lansoprazole 30 mg/day PO; rabeprazole 20 mg/day PO; esomeprazole 40 mg/day PO; pantoprazole 40 mg/day PO; dexlansoprazole 30 mg/day PO
  - Length of treatment: 4–8 weeks
- H$_2$ blockers
  - ranitidine or nizatidine 150 mg PO BID or 300 mg PO at bedtime; cimetidine 400 mg PO BID or 800 mg PO at bedtime; famotidine 20 mg PO BID or 40 mg PO at bedtime
  - Length of treatment: 4–8 weeks
- **Precautions:**
  - Decrease H$_2$ blocker dosage by 50% if CrCl <50 mL/min
  - PPIs may decrease bone density. Obtain interval bone densitometry with long-term PPI use (2).
  - PPIs may cause hypomagnesemia.
  - PPIs may be associated with increased risk of Clostridium difficile infection (2).
  - Short-term PPI use associated with development of community-acquired pneumonia; long-term use does not appear to have an increased risk.
  - Despite earlier concerns, PPIs do not appear to decrease the efficacy of clopidogrel (2).
- **NSAID-induced ulcers**
  - Discontinue NSAID use.
  - Treat with PPIs for 4–8 weeks; may use as maintenance for patients with recurrent, complicated, or idiopathic ulcers; or in patients who require long-term aspirin or NSAID use.
- **H. pylori-induced ulcers**
  - H. pylori eradication regimens
    - Clarithromycin-based triple therapy for 14 days: standard dose PPI PO BID plus clarithromycin 500 mg PO BID plus amoxicillin 1 g PO BID
    - Bismuth based quadruple therapy for 14 days: standard dose PPI PO BID plus clarithromycin 500 mg PO BID plus amoxicillin 1 g PO BID
Metronidazole based therapy for patients with amoxicillin allergy: standard dose PPI PO BID plus metronidazole 500 mg PO BID plus clarithromycin 500 mg PO BID

Sequential therapy: standard dose PPI PO BID plus 1g amoxicillin PO BID for 5 days followed by PPI PO BID plus clarithromycin 500 mg PO BID and tinidazole 500 mg PO BID for 5 days

Second Line
- For H. pylori eradication: Use second-line therapy if first-line fails:
  - Bismuth quadruple therapy for 14 days
    - Bismuth subsalicylate 525 mg PO QID and
    - Metronidazole 250 mg PO QID plus
    - Tetracycline 500 mg PO QID plus
    - Standard dose PPI PO BID
  - Another alternative salvage therapy:
    - PPI orally BID
    - Amoxicillin 1,000 mg PO BID plus
    - Rifabutin 300 mg PO daily plus
- Alternative ulcer-healing drugs:
  - Sucralfate and antacids
- Significant possible interactions:
  - Cimetidine inhibits cytochrome P450 isozymes (avoid with theophylline, warfarin, phenytoin, and lidocaine).
  - Omeprazole may prolong elimination of diazepam, warfarin, and phenytoin.
  - Sucralfate reduces absorption of tetracycline, norfloxacin, ciprofloxacin, and theophylline; it leads to subtherapeutic levels.

Pregnancy Considerations
PPIs are not associated with an increased risk for major birth defects, spontaneous abortions, or preterm delivery.
- Breastfeeding
  - Both ranitidine and esomeprazole are secreted in breast milk at considerably lower doses than used for treatment in infants with reflux disease. Use in breastfeeding women is generally safe.

ISSUES FOR REFERRAL
Refer for endoscopy if red flag signs are present:
- Onset of symptoms after age 55 years
- Progressive dysphagia
- Recurrent vomiting
- Heme positive stool, melena, hematemesis, anemia
- Progressive dysphagia or persistent/recurrent vomiting
- Severe abdominal pain
- Weight loss, anorexia, or family history of gastric malignancy

SURGERY/OTHER PROCEDURES
- Endoscopy is indicated for patients age >55 years with new onset of dyspeptic symptoms, those who do not respond to treatment, and patients of any age with alarm/red flag symptoms (3)[B].
During endoscopy:
- Biopsy stomach for H. pylori testing (CLO test)
- Biopsy ulcer margin to exclude malignancy
- Interventions to stop active bleeding or prevent rebleeding in those with certain stigmata include injection with epinephrine, heater probe treatment, or placement of endoscopic clips (2).

Emergent surgery is the treatment for ulcer perforation.
Surgery is rarely needed due to effective medical treatment of ulcers and H. Pylori infection.
Non-emergent indications for surgery: ulcers that are refractory to treatment; patients at high risk for complications (e.g., transplant recipients, patients dependent on steroids/NSAIDs); bleeding not responding to endoscopic therapy (4)

Surgical options:
- Duodenal ulcers: truncal vagotomy and drainage (pyloroplasty/gastrojejunostomy), selective vagotomy (preserving the hepatic and/or celiac branches of the vagus) and drainage, or highly selective vagotomy (1)
- Gastric ulcers: partial gastrectomy, Billroth I or II
- Perforated ulcers: laparoscopy/open patching (1)

Emerging options: Vonoprazan is a novel acid blocker that is non-inferior to PPIs.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Discontinue ulcerogenic agents (e.g., NSAIDs).
- Bleeding peptic ulcers
  - Stable: Give PPI to reduce transfusion requirements, need for surgery, and duration of hospitalization (5).
  - Unstable: fluid/packed RBC resuscitation followed by emergent esophagogastroduodenoscopy (EGD) or surgery; use IV PPI.
  - Insufficient evidence for high-dose PPI treatment over lower doses in peptic ulcer bleeding (2)[A]
- Oral PPI equivalent to IV after endoscopic treatment (5)
- Perforated peptic ulcers are a surgical emergency (1).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- H. pylori eradication: expected in >90% (with double antibiotic regimen): Confirm eradication with urea breath test or fecal antigen test.
- Acute duodenal ulcer: Monitor clinically.
- Acute gastric ulcer: Confirm healing via endoscopy after 12 weeks; biopsies (if not done initially) to confirm benign mucosa.

PROGNOSIS
After H. pylori eradication (3):
- Low ulcer relapse rate; if relapse, consider use of NSAIDs or tobacco
- Reinfection rates <1% per year
- Low risk of rebleeding
Decreased NSAID ulcer recurrence (3)

COMPLICATIONS
- Hemorrhage: up to 25% of patients (initial presentation in 10%)
- Perforation: <5% of patients
- Gastric outlet obstruction: up to 5% of duodenal or pyloric channel ulcers; male predilection found
- Risk of gastric adenocarcinoma is increased in H. pylori-infected patients.
- Refractory peptic ulcer disease (5–10% after eradication of H. pylori or completion of 12 weeks of PPI)

REFERENCES

ADDITIONAL READING

CODES
ICD10
- K27.9 Peptic ulc, site unsp, unsp as ac or chr, w/o hemor or perf
- K26.9 Duodenal ulcer, unspecified as acute or chronic, without hemorrhage or perforation
- K25.9 Gastric ulcer, unspecified as acute or chronic, without hemorrhage or perforation

CLINICAL PEARLS
- PPIs have higher efficacy than H₂ blockers for healing duodenal ulcers.
- In patients with PUD, eradicate H. pylori to assist healing and reduce the risk of recurrence.
- Upper endoscopy is indicated for patients with suspected peptic ulcers and red flag symptoms and for those who do not respond to treatment.
PERICARDITIS
Veronica J. Ruston, DO

BASICS

DESCRIPTION
Inflammation of the pericardium, with or without associated pericardial effusion. Myopericarditis or perimyocarditis refers to cases that have myocardial involvement in addition to involvement of the pericardium.

EPIDEMIOLOGY

Incidence
- Epidemiologic studies are lacking. Exact incidence is unknown but occurs in up to 5% of patients evaluated in the emergency room (ER) for chest pain without myocardial infarction (MI), including children; appears to be a slightly increased prevalence in men ages 16–65 years old.
- After first episode of acute pericarditis, about 30% of patients will experience recurrence within next 18 months.

ETIOLOGY AND PATHOPHYSIOLOGY
- Inflammation of the pericardial sac can be acute, chronic (disease process lasting >3 months), or recurrent (subsequent episode after 4–6 weeks without symptoms). Chronic or recurrent inflammation may result in constrictive pericarditis.
- Can produce serous/purulent fluid/dense fibrinous material (depending on etiology), which may or may not lead to hemodynamic compromise
- Idiopathic: 85–90% of cases; likely related to viral infection, which may trigger immune-related process
- Infectious
  - Viral: coxsackievirus, echovirus, adenovirus, Epstein-Barr virus, cytomegalovirus, hepatitis viruses, influenza virus, HIV, measles, mumps, varicella
  - Bacterial: Mycobacterium tuberculosis (common in endemic countries), other bacterial causes rare
  - Fungal (more common in immunocompromised populations): Blastomyces dermatitidis, Candida sp., Histoplasma capsulatum
  - Parasites: Echinococcus
- Noninfectious causes
  - Acute MI (2 to 4 days after MI), Dressler syndrome (weeks to months after MI)
  - Aortic dissection
  - Renal failure, uremia, dialysis-associated
  - Malignancy (e.g., breast cancer, lung cancer, Hodgkin disease, leukemia, lymphoma)
  - Radiation therapy
  - Trauma
  - After cardiac procedures (e.g., catheterization, pacemaker placement, ablation, pericardiomyotomy)
  - Autoimmune disorders: connective tissue disorders, systemic lupus erythematous (SLE),
Medication-induced: dantrolene, doxorubicin, hydralazine, isoniazid, mesalamine, methysergide, penicillin, phenytoin, procainamide, rifampin

Genetics
No known factors

RISK FACTORS
Thoracic surgery, chronic kidney disease, pneumonia, autoimmune diseases, lung or breast cancer especially if treated with radiation therapy

GENERAL PREVENTION
Good hygiene including hand washing and use of masks

COMMONLY ASSOCIATED CONDITIONS
Depends on etiology

DIAGNOSIS
- Diagnostic clinical criteria
  - Acute pericarditis (at least two of four criteria)
    - Typical (pleuritic) chest pain
    - Pericardial friction rub (<33% of cases)
    - ECG changes with widespread (non-regional) ST-segment elevations (up to 60% of cases)
    - New/increasing pericardial effusion seen on imaging
  - Myopericarditis
    - 1. Definite pericarditis and
    - 2. Symptoms (dyspnea, chest pain, or palpitations) and ECG changes not previously documented (ST/T wave abnormalities, supraventricular/ventricular tachycardia) or focal/diffuse depressed left ventricular (LV) function documented on imaging study
    - 3. Absence of evidence of other cause
    - 4. One of the following: elevated cardiac enzymes (creatine kinase [CK]-MB, troponin I or T) or new focal/diffuse depressed LV function or abnormal imaging consistent with myocarditis (MRI with gadolinium, gallium-67 scanning, antimiysosin antibody scanning)
- Case definitions of myopericarditis using above criteria:
  - Suspected myopericarditis: criteria 1, 2, and 3
  - Probable myopericarditis: criteria 1, 2, 3, and 4
  - Confirmed myopericarditis: histopathologic evidence of myocarditis by endomyocardial biopsy (EMB) or autopsy (Note: In the clinical setting, for self-limited cases with predominantly pericarditis, EMB is rarely indicated.)

HISTORY
- Prodrome of fever, malaise, myalgias, viral upper respiratory
- Acute, sharp, stabbing chest pain, pathognomonic if pain radiates to trapezius
- Duration typically hours to days
- Pleuritic pain
- Pain reduced by leaning forward, worsened by lying supine

rheumatoid arthritis, scleroderma, hypothyroidism, inflammatory bowel disease, Wegener granulomatosis, spondyloarthropathies, sarcoidosis
- Shortness of breath

**PHYSICAL EXAM**
- Heart rate is usually regular but may be rapid
- Pericardial friction rub: coarse, high-pitched sound best heard during end expiration at left lower sternal border with patient leaning forward. Highly specific for diagnosis (but not sensitive); may be transient and mono-, bi-, or triphasic
- New S₃ may suggest myopericarditis
- Cardiac tamponade

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- It is not necessary to order tests for uncomplicated cases or when the diagnosis is clear, especially in countries with low prevalence of tuberculosis. Following labs may be helpful:
  - CBC: typically shows leukocytosis
  - Inflammatory markers: elevated erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and lactate dehydrogenase (LDH)
  - Cardiac biomarkers: typically elevated CK, troponins
    - Elevated troponins associated with younger age, male sex, pericardial effusion at presentation, and ST segment elevation on ECG
    - Adverse outcomes are not predicted by elevated troponin.
- ECG: Findings include widespread upward concave ST segment elevation (in all or most leads, a diffuse, nonregional process) and PR segment depression that may evolve through four stages. ECG may be normal/show nonspecific abnormalities:
  - Stage 1: diffuse ST segment elevation and PR segment depression
  - Stage 2: Normalization of the ST and PR segments and T waves begin to flatten and invert.
  - Stage 3: widespread T wave inversions
  - Stage 4: normalization of T waves; may have persistent inversions if chronic pericarditis
- ECG may demonstrate low voltage and electrical alternans with large effusions and tamponade.
- Transthoracic echocardiogram is recommended to evaluate for the presence of pericardial effusion, tamponade, or myocardial disease (presence of effusion helps to confirm diagnosis of pericarditis). Effusions are readily diagnosed on echo.
- Chest x-ray (CXR) is performed to rule out pulmonary/mediastinal pathology. Enlarged cardiac silhouette suggests large pericardial effusion (at least 300 mL).
- CT and MRI allow visualization of pericardium to assess for complications or if initial workup is inconclusive.
- Additional testing (if clinically appropriate based on history or atypical presentation or course) may include tuberculin skin test, sputum cultures, rheumatoid factor, antinuclear antibody, and HIV serology.
- Viral cultures and antibody titers rarely clinically useful

**Diagnostic Procedures/Other**
- Pericardiocentesis indicated for cardiac tamponade; for suspected purulent, tuberculous, or neoplastic pericarditis; and for effusions >20 mm on echocardiography (1)[C]
- Surgical drainage with pericardial biopsy recommended if recurrent tamponade, ineffective pericardiocentesis, or hemodynamic instability (1)[C]
Test Interpretation
- Microscopic examination may reveal hyperemia, leukocyte accumulation, or fibrin deposition.
- Purulent fluid with neutrophilic predominance if bacterial etiology
- Lymphocytic predominance in viral, tuberculous, and neoplastic pericarditis

TREATMENT
- Goal of treatment is to relieve pain and reduce complications (e.g., recurrence, tamponade, chronic constrictive pericarditis).
- Outpatient therapy is reported to be successful in 85% patients with low-risk features.

GENERAL MEASURES
Specific therapy directed toward underlying disorder for patients with identified cause other than viral/idiopathic disease. Restrictions of physical activity are an important part of treatment for recurrences.

MEDICATION

First Line
- NSAIDs are considered the mainstay of therapy for acute pericarditis:
  - Ibuprofen 600 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper (2)[C]
  - Aspirin 750–1000 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; preferable for patients with recent MI because other NSAIDs impair scar formation in animal studies (2)[C],[3][C]
  - Indomethacin 50 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; should avoid in elderly due to flow restriction to coronaries (4)[C]
  - Ketorolac 15 to 30 mg IV/IM q6h while inpatient; maximum duration of 5 days (4)[C]
  - GI protection should be provided (4)[C].
  - Tapering should be done only if the patient is asymptomatic and CRP/ESR are normal. Repeat CRP/ESR every 1 to 2 weeks (4)[C].
  - Treatment duration using NSAIDs for initial attacks is 1 to 2 weeks, but for recurrences, consider 2 to 4 weeks of therapy (4)[C].
  - Monitoring: NSAIDs: CBC and CRP at baseline and weekly until CRP normalizes
  - Contraindications: hypersensitivity to aspirin or NSAIDs, active peptic ulcer/GI bleeding
  - Precautions: Use with caution in patients with asthma, 3rd-trimester pregnancy, coagulopathy, and renal/hepatic dysfunction.

- Colchicine: common practice to use in combination with NSAIDs to decrease incidence of recurrence and for faster symptomatic response; 0.6 mg BID for up to 3 months (up to 6 months for recurrence); taper is not required. This is the only agent proven to prevent recurrences in RCTs. Adjunctive therapy can reduce rate of recurrence by 50% (1)[A]. Monitoring: Consider CBC, CRP, transaminases, CK, and creatinine at baseline and after 1 month at a minimum.

- Pregnant: <20 weeks’ gestation: Aspirin is first choice, but NSAIDs and prednisone are also allowed; >20 weeks’ gestation: Prednisone is allowed with avoidance of NSAIDs, aspirin, and colchicine.

Second Line
Corticosteroid treatment is indicated in connective tissue disease, tuberculous pericarditis, or severe recurrent symptoms unresponsive to NSAIDs or colchicine; should be avoided in uncomplicated acute pericarditis or if infectious etiology is suspected. Corticosteroid use alone has been found to be an independent risk factor for recurrence (3)[C].

If steroids are used, consider low dose (0.20 to 0.50 mg/kg/day until resolution of symptoms and normalization of CRP, then consider slow tapering (if >50 mg: 10 mg/day every 1 to 2 weeks; if 25 to 50 mg: 5 to 10 mg/day every 1 to 2 weeks; if 15 to 25 mg: 2.5 mg/day every 2 to 4 weeks; if <15 mg/day: 1.0 to 2.5 mg/day every 2 to 6 weeks). At threshold of 10–15 mg/day, decrease taper to 1.0–2.5 mg every 2–6 weeks to prevent recurrence (2)[C].

Remember adequate prophylaxis treatment for osteoporosis prevention (3)[C].

If recurrence while tapering, try to not increase dose or restart corticosteroids (2)[C].

Intrapericardial administration of steroids may be effective and limits systemic side effects.

Emerging alternative options include azathioprine, IV human immunoglobulins, and anakinra (3)[C].

ISSUES FOR REFERRAL

Hospitalization and evaluation for etiology recommended for any patient with major medical comorbidities, for suspected or threatened tamponade, for poor prognostic factors (see next column), or for a presentation that suggests an underlying systemic inflammatory disease (2)[C].

Refractory cases include those on unacceptably high long-term steroid doses (>25 mg/day).

Consider trial of aspirin and/or NSAIDs plus steroid and colchicine.

Uremic or dialysis-related cases require more frequent or urgent dialysis without significant benefit from pharmacologics.

SURGERY/OTHER PROCEDURES

Pericardiocentesis is indicated in cases of cardiac tamponade, high likelihood of tuberculous/purulent/neoplastic pericarditis, and moderate-to-large symptomatic effusions refractory to medical therapy.

Pericardial biopsy may be considered for diagnosis in those with persistent worsening pericarditis without a definite diagnosis.

Pericardioscopy for targeted diagnostic imaging may be performed at experienced tertiary referral centers in refractory and difficult cases.

Pericardial window may be performed in cases of recurrent cardiac tamponade with large pericardial effusion despite medical therapy and severe symptoms.

Pericardiectomy is standard of care for chronic constrictive pericarditis with persistent symptoms, such as NYHA class III or IV. Mortality is high at 6–12% so is reserved only after careful evaluation by experienced surgeons at hospitals with specific interest in pericardial diseases (2)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Inpatient therapy recommended for pericarditis associated with clinical predictors of poor prognosis:

- Major predictors: fever >38°C, subacute onset, large pericardial effusion, cardiac tamponade, lack of response to NSAID/aspirin therapy after at least 1 week (2)[C]
- Minor predictors: immunosuppressed state, trauma, oral anticoagulation therapy, myopericarditis (5)[C]
- IV fluids considered for hypotension or in the setting of pericardial tamponade
- Discharge criteria
  - Response to therapy with symptom improvement
  - Hemodynamic stability

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- 7 to 10 days to assess response to treatment
- 1 month to check CBC and CRP and thereafter if symptoms continue to be present
- Those with clinical predictors of poor prognosis may require closer follow-up based on lab data and echocardiographic findings.

**Patient Monitoring**

*Myopericarditis*
- Use lower doses of anti-inflammatory drugs to control symptoms for 1 to 2 weeks while minimizing deleterious effects on myocarditic process.
- Exercise restrictions for 4 to 6 weeks or until symptoms resolved and biomarkers normalized. For athletes, exercise restriction should be a minimum of 3 months after symptom onset.
- Echocardiographic monitoring at 1, 6, and 12 months (especially in those with LV dysfunction)

**DIET**
Specific to underlying etiology only

**PROGNOSIS**
Overall good prognosis; disease usually benign and self-limiting; purulent and tuberculosis pericarditis with high mortality

**COMPLICATIONS**
- Recurrent pericarditis: occurs in ~30% of patients, with most instances resulting from idiopathic, viral, or autoimmune pericarditis; inadequate treatment of the initial attack; and, less commonly, neoplastic etiologies. Recurrence usually within 1st week following initial episode but may occur months to years later; rarely associated with tamponade/constriction
- About 5% of patients develop corticosteroid dependence and colchicine resistance.
- Cardiac tamponade: rare complication with increased incidence in neoplastic, purulent, and tuberculous pericarditis
- Effusive-constrictive pericarditis: reported in 24% of patients undergoing surgery for constrictive pericarditis and in 8% of patients undergoing pericardiocentesis and cardiac catheterization for cardiac tamponade. Failure of right atrial pressure to fall by 50% or to a level below 10 mm Hg after pericardiocentesis is diagnostic.
- Constrictive pericarditis: rare complication in which rigid pericardium produces abnormal diastolic filling with elevated filling pressures. Pericardieotomy remains definitive therapy.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- I31.9 Disease of pericardium, unspecified
- I30.9 Acute pericarditis, unspecified
- I30.1 Infective pericarditis

CLINICAL PEARLS

- Therapy aimed at symptomatic relief and NSAIDs are first-line treatment. Colchicine is recommended as an adjunct to NSAIDs and has been shown to decrease risk of recurrence by 50%.
- Pericardiocentesis is recommended in the setting of cardiac tamponade or possible purulent pericarditis.
- Depending on risk factors and presentation, some patients should be hospitalized initially for treatment.
PERIODIC LIMB MOVEMENT DISORDER (PLMD)
Denise Sharon, MD, PhD, FAASM • Rochelle Zak, MD

BASICS

DESCRIPTION
Sleep-related movement disorder characterized by periodic limb movements of sleep (PLMS) with significant sleep disturbance and/or daytime functional impairment:

- Periodic limb movements of sleep (PLMS) demonstrated during polysomnography
- PLMS are repetitive contractions of the tibialis anterior muscles occurring mainly in non-rapid eye movement (NREM) sleep.
- Movements consist of unilateral or bilateral, simultaneous or not, rhythmical extension of the big toe and ankle dorsiflexion.
- Sometimes, knee and hip flexion is noted.
- Arm movements or more generalized movements occur less commonly.
- Movements might be associated with cortical arousals from sleep unbeknownst to the patient (PLMs with arousals—PLMA).
- A clinical history of significant sleep disturbance and/or functional impairment is necessary for diagnosis
- Complaints include insomnia, nonrestorative sleep, daytime fatigue, somnolence.
- Bed partner may complain of patient’s movements.
- Other sleep disorders such as obstructive sleep apnea (OSA), narcolepsy, restless legs syndrome do not explain the PLMS (1)[A].
- No associated restlessness or dysesthesia while awake
  – If there is an associated sensory perception or restlessness, the diagnosis is not PLMD but possibly restless leg syndrome (RLS).
- System(s) affected: musculoskeletal, nervous
- Synonym(s) referring to the PLMS: nocturnal myoclonus; sleep myoclonus

EPIDEMIOLOGY

Incidence
- PLMD is rare, affecting children and adults (2).
- PLMS occurs in >15% of insomnia patients.
- PLMS are frequent in rapid eye movement (REM) sleep behavior disorder (RBD) occurring during REM sleep.
- PLMS are frequent in narcolepsy, in OSA, and during initiation of continuous positive airway pressure.

Prevalence
- No sex preference; male = female
- PLMS >5/hr is uncommon before age 40 years.
- PLMS increases with age: 45% of patients >65 years exhibit PLMS >5/hr but not PLMD.
- PLMD is much less common: <5% of adults but also underdiagnosed (2).
- 85% of RLS patients have PLMS (3).
ETIOLOGY AND PATHOPHYSIOLOGY
- Understudied; most data reports on PLMS as it pertains to RLS:
  - Brain iron deficiency causing central nervous system (CNS) dopamine dysregulation
  - Suprasegmental disinhibition at the brainstem and spinal cord levels
  - Spinal cord excitability
  - CNS dopamine dysregulation supported by increased incidence of PLMS in untreated Parkinson disease (PD) and decreased incidence of PLMS in schizophrenia.
- Triggering and exacerbating factors:
  - Peripheral neuropathy
  - Arthritis
  - Renal failure
  - Synucleinopathies (multiple-system atrophy)
  - Spinal cord injury
  - Pregnancy
- Medications
  - Most antidepressants (except bupropion or desipramine) and lithium
  - Some antipsychotic and antidementia medications
  - Antiemetics (metoclopramide)
  - Sedating antihistamines

Genetics
BTBD9 on chromosome 6p associated with PLMS in patients with or without RLS but not in RLS patients without PLMS

RISK FACTORS
- Family history of RLS
- Iron deficiency and associated conditions
- Peripheral neuropathy
- Arthritis, orthopedic problems
- Chronic limb pain or discomfort

GENERAL PREVENTION
- Promoting adequate sleep
- Avoid PLMS triggers such as iron deficiency, frequently observed in children (4).
- Awareness, including family history

COMMONLY ASSOCIATED CONDITIONS
- Narcolepsy
- Iron deficiency
- End-stage renal disease (ESRD)
- Cardiovascular disease; stroke
- Gastric surgery
- Pregnancy
- Arthritis
- Synucleinopathies-multiple-system atrophy
- Lumbar spine disease; spinal cord injury
- Peripheral neuropathy
- Insomnia, insufficient sleep, parasomnias
• Attention deficit hyperactivity disorder (ADHD)
• Mood disorder, anxiety, oppositional behaviors

**Pediatric Considerations**
• PLMD may precede overt RLS by years (4).
• Association with RLS is more common.
• Symptoms may be more resultant than in adults (5)[B].
• Association and differential diagnosis with ADHD, oppositional behaviors, mood disorders, growing pains (4)

**Pregnancy Considerations**
PLMD is not well studied in pregnant women; implying from literature on RLS with PLMS in pregnant women:
• May be secondary to iron, folate deficiency
• Most severe in the 3rd trimester
• Usually resolves after delivery

**Geriatric Considerations**
• Potential source of sleep disturbance
• May cause or exacerbate circadian disruption and “sundowning”
• Medications that may trigger or exacerbate PLMs, which can lead to PLMD or RLS.
• There is a growing literature suggesting an increase risk of atrial fibrillation with PLMS.

**DIAGNOSIS**

**HISTORY**
• Sleep disturbance:
  – Insomnia: difficulty maintaining sleep
  – Nonrestorative sleep
  – Daytime fatigue, tiredness, somnolence
  – Oppositional behaviors
  – Memory impairment
  – Depression
  – ADHD, particularly in children (4)
• The PLMS and the symptoms cannot be better explained by another current sleep disorder, medical, neurologic, or mental disorder.

**PHYSICAL EXAM**
No specific findings

**DIFFERENTIAL DIAGNOSIS**
• PLMS occurring with RLS, RBD, narcolepsy, are secondary to the sleep disorder, not PLMD.
• PLMS occurring with OSA may be associated with respiratory events and is not PLMD.
• Sleep starts: nonperiodic, generalized, only at wake–sleep transition, <0.2 duration
• Sleep-related leg cramps: isolated, painful, muscle knots
• Fragmentary myoclonus: 75 to 150 ms of electromyographic (EMG) activity, minimal movement, no periodicity
- Nocturnal seizures: epileptiform electroencephalogram, motor pattern incongruent with PLMs
- Fasciculations, tremor: no sleep association
- Sleep-related rhythmic movement disorder: voluntary movement during wake–sleep transition; higher frequency than PLMs
- Growing pains in children—pain is the concern.

**DIAGNOSTIC TESTS & INTERPRETATION**

Polysomnography (PSG) demonstrating PLMS:
- Tibialis anterior EMG activation lasting 0.5–10.0
- EMG amplitude increase >8 μV from baseline
- Movements occur in a sequence of ≥4 at intervals of 5 to 90 seconds.
- Associated with heart rate variability from autonomic-level arousals
- Most PLMs episodes occur in the first hours of NREM sleep.
- Night-to-night PLMS variability is common.

**Initial Tests (lab, imaging)**

Serum iron stores including ferritin, transferrin, iron-binding capacity, serum iron are used to assess for iron deficiency (at least ferritin):
- Serum ferritin should be >75 ng/mL.
- Transferrin saturation >16%

**Follow-Up Tests & Special Considerations**

Repeat iron stores, at least ferritin if suspected change, or nonresponsive to treatment

**Diagnostic Procedures/Other**

EMG, nerve conduction studies for peripheral neuropathy/radiculopathy if indicated

**Test Interpretation**

On PSG: PLMSI >5/hr children, and >15/hr adults

**TREATMENT**

Treatment paradigm similar to that for RLS, except that all medications are off-label for PLMD (1,3,6)[B]

**GENERAL MEASURES**

- Assess for and correct iron insufficiency.
- Adequate nightly sleep
- Regular exercise, low impact, stretches in the evening
- Weighted blanket, warm the legs (long socks, leg warmers, electric blanket, etc.)
- Hot/leg baths, warm soaks before bedtime
- Avoid caffeine and alcohol.

**MEDICATION**

- Use minimum effective dose.
- Goals of medication:
  - Improve subjective sleep quality.
  - Control PLMS and their effect on sleep.
Consider risks, side effects, interactions in different populations (e.g., benzodiazepines in elderly). 
Treatment should decrease daytime somnolence.

**First Line**
Currently debated—use clinical judgment
- Dopamine agonists reduce PLMS, increase sleep efficiency but have no effect on sleep instability; start low, titrate slow to optimal dose (1,3,6)[C]
  - Pramipexole (Mirapex): 0.125–0.5 mg; titrate by 0.125 mg; take 2h hs
  - Ropinirole (Requip): 0.25–4.00 mg; titrate by 0.25 mg; take 1/2 to 1 h hs; preferred in renal impairment
  - Transdermal rotigotine (Neupro): 1–3 mg/24 hr patch; initiate with 1 mg/24 hr; titrate up by 1 mg slowly to effectiveness.
- Avoid dopamine agonists in psychotic patients, especially if taking dopamine antagonists.
- Dopamine agonists may exert a stimulant effect, further disturbing sleep.

**Second Line**
- Voltage-gated calcium channel α2δ subunit ligands: useful for associated neuropathy; decrease PLMS and improve sleep architecture; caution with renal impairment (1,3)[C]
  - Gabapentin enacarbil (Horizant): 600 mg early evening
  - Gabapentin (Neurontin) 300–600 mg hs
  - Pregabalin (Lyrica): 75–300 mg hs
- Benzodiazepines and agonists (1,3)[C]; most commonly used because of their effect on sleep; caution in the elderly
  - Clonazepam (Klonopin): 0.5–2.0 mg qhs
  - Zaleplon, zolpidem, temazepam, triazolam, alprazolam, diazepam
- Opioids: low risk for tolerance with bedtime dose; most commonly used when other treatments fail; can decrease respiratory drive
  - Hydrocodone: 5–20 mg/day
  - Oxycodone: 2.5–20.0 mg/day

**ISSUES FOR REFERRAL**
To sleep medicine clinic, neurology and movement disorders clinic:
- High-dose medications
- Worsening of Sx while on medications
- Intractable iron deficiency

**Pediatric Considerations**
- First-line treatment: nonpharmacologic (4)[C]
- Assess/correct iron deficiency (5)[B].
- Consider low-dose clonidine 0.1–0.3 mg hs; caution: orthostatic hypotension (4)[C]

**Pregnancy Considerations**
- Initial approach: iron supplementation, nonpharmacologic therapies (6)
- Avoid medications Class C or D.
- In 2nd, 3rd trimester, can use clonazepam 0.25–1 mg qhs
- Carbidopa/levodopa 25/100–50/200 ER
- Refractory PLMD—may use oxycodone in 2nd, 3rd trimester: d/c 2 wks prior delivery
Geriatric Considerations
In weak or frail patients, avoid medications that may cause dizziness or unsteadiness.

ADDITIONAL THERAPIES
- If iron deficient, iron supplementation:
  - 325-mg ferrous sulfate with 200 mg vitamin C between meals BID or entire dose QD.
  - Repletion may require months of treatment.
  - Symptoms continue without other treatment
- Clonidine 0.05–0.30 mg/day
- Relaxis leg vibration device; limited data

SURGERY/OTHER PROCEDURES
Correction of orthopedic, neuropathic, or peripheral vascular problems

COMPLEMENTARY & ALTERNATIVE MEDICINE
Vitamin/mineral supplements, including calcium, magnesium, vitamin B₁₂, folate

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Control during recovery from orthopedic procedures
- Addition/withdrawal of meds that affect PLMD
- Changes in medical status may require medication changes (e.g., pramipexole contraindicated in renal failure; ropinirole contraindicated in liver disease).
- Consider IV iron when oral supplementation is ineffective, not tolerated, contraindicated
- When NPO, consider IV opiates, rotigotine
- Evening walks, hot baths/soaks, leg warming

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- At monthly intervals until stable
- Assess symptom severity, medication side effects, augmentation
- Annual and PRN follow-up thereafter
- Repeat iron blood work if previously low.

DIET
Avoid caffeine, alcohol, moreso late in the day

PATIENT EDUCATION
- National Sleep Foundation: https://www.sleepfoundation.org/
- American Academy of Sleep Medicine: https://www.sleepeducation.org/

PROGNOSIS
- Primary PLMD: lifelong, no current cure
- Secondary PLMD: may subside with resolution of cause(s) such as low iron stores
- Current therapies usually control symptoms.
- PLMD often precedes the emergence of RLS.
COMPLICATIONS
Mostly based on RLS data
- Tolerance to meds requiring increased dose
- Augmentation (increased PLMs and sleep disturbance, emergence of RLS) from dopamine agonists:
  - Higher doses increase risk.
  - Iron deficiency increases augmentation risk.
  - Add alternative medication and then gradually discontinue dopaminergic agent.
- Iatrogenic PLMD (from antidepressants, etc.)

REFERENCES

ADDITIONAL READING

SEE ALSO
Restless Leg Syndrome
CLINICAL PEARLS

- Many patients with PLMs may not require treatment; when sleep disturbance associated with PLMs causes insomnia and/or daytime consequences, PLMD should be treated.
- Ensuring adequate iron stores, with a ferritin >75 is advised.
- Many antidepressants and some antihistamines cause or exacerbate PLMs.
PERIPHERAL ARTERIAL DISEASE
Keshav Kukreja, MD • Adrian DaSilva-DeAbreu, MD • Raymundo A. Quintana, MD

BASICS
DESCRIPTION
Peripheral arterial disease (PAD) represents atherosclerotic occlusive disease of the peripheral arteries, most commonly in the lower extremities. Following coronary artery disease and cerebrovascular disease, PAD is the third leading source of atherosclerotic vascular morbidity. PAD manifests as intermittent claudication (IC) or atypical leg pain and is commonly diagnosed with a resting ankle-brachial index (ABI) of <0.90.

EPIEMIOLOGY
● Age: >65 years
  – Age: 50 to 64 years with risk factors for atherosclerosis or a family history of PAD
  – Age: <50 years in the presence of diabetes mellitus (DM) and one additional risk factor
● Sex: male > female (2:1)
● Impacts at least 8.5 million people in the United States
● Globally, an estimated 202 million people have PAD with increased prevalence in low- and middle-income countries.

Incidence
● Annual incidence is 7.1/1,000 men and 3.6/1,000 women among all ages, per Framingham Heart Study.
● Incidence increases with age and the presence of cardiovascular risk factors.

Prevalence
● U.S. prevalence: 5.9% in adults >40 years
● Prevalence approaches 30% in high-risk populations.
● Higher prevalence and severity in African Americans and Hispanics

ETIOLOGY AND PATHOPHYSIOLOGY
● In PAD, arterial occlusion is most commonly a result of underlying atherosclerotic disease.
● Other etiologies for PAD include phlebitis, trauma, or autoimmune/vasculitic diseases.
● Arterial narrowing results in insufficient oxygen delivery to the muscle during periods of increased demand (i.e., exercise), causing claudication and limiting exercise.
● Reperfusion at rest following ischemia can result in multiple subsequent physiologic changes, including inflammation, oxidant stress, endothelial dysfunction, and mitochondrial injury.

Genetics
Although several of the risk factors for PAD (as noted below) are heritable, genome-wide association studies isolating PAD-specific single nucleotide polymorphisms have not been as successful. This has been attributed to the increased clinical and genetic heterogeneity of PAD.

RISK FACTORS
- Age >65 years
- Cigarette smoking
- DM
- Obesity
- Hypertension (HTN)
- Hyperlipidemia (HLD)
- Chronic kidney disease (CKD)
- Hyperviscosity
- Heritable conditions: chylomicronemia, hypercholesterolemia, hyperhomocysteinemia, and pseudoxanthoma elasticum

**GENERAL PREVENTION**
- Regular aerobic exercise program
- Smoking cessation
- Blood pressure (BP) and diabetes control
- Statin therapy is indicated in patients with clinical PAD for secondary prevention of atherosclerotic cardiovascular disease.

**COMMONLY ASSOCIATED CONDITIONS**
In addition to the aforementioned risk factors, PAD is associated with other forms of atherosclerotic disease including myocardial infarction (MI), transient ischemic attack (TIA), and cerebrovascular accident (CVA).

**DIAGNOSIS**

**HISTORY**
- Nearly 50% of patients will be asymptomatic.
- IC seen in 10–30% of patients and is typically self-limiting with symptoms resolving within 2 to 5 minutes of rest
- Atypical or resting leg pain in 20–40% of patients
- Critical limb ischemia (pain and/or tissue loss)
- Nonhealing wounds and ulceration
- Skin discoloration and gangrene
- Erectile dysfunction (in conjunction with IC and absent or diminished femoral pulses constitutes Leriche syndrome)

**PHYSICAL EXAM**
- Pallor with leg elevation
- Dependent rubor
- Dry, scaly skin
- Brittle or hypertrophic nails
- Hair loss
- Reduced/absent extremity pulses
- Ulcers (distal toes, lateral malleolus, metatarsal heads)

**DIFFERENTIAL DIAGNOSIS**
- Arterial aneurysm or dissection
Deep vein thrombosis (DVT)
• Thromboangiitis obliterans (Buerger disease)
• Peripheral neuropathy
• Spinal stenosis or nerve root compression (neurogenic claudication)
• Popliteal entrapment syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Screening
• The association between PAD and cardiovascular morbidity and mortality has been well established, with a lower ABI being an independent predictor.
• Patients at increased risk (criteria below) should undergo thorough history, review of systems, and physical examination with a focus on exertional leg symptoms (IC), pain at rest, and nonhealing wounds.
• Also important is a vasculature exam, including assessment of lower extremity pulses, auscultation for femoral bruits, inspection of legs and feet, and BP measurement in both arms (1)[C].
  – Age ≥65 years
  – Age 50 to 64 years with risk factors for atherosclerosis (DM, smoking, HTN, HLD)
  – Age <50 years with DM and one additional risk factor
  – Patients at any age with known atherosclerotic disease elsewhere

Initial Tests (lab, imaging)
• Risk factor identification with fasting lipid profile and basic metabolic profile
• Resting ABI should be performed in patients with suggestive history and physical findings or those at increased risk of PAD (1)[C].
• Exercise treadmill ABI is useful in patients who are symptomatic but have normal resting ABI.
• Imaging is reserved for patients who have lifestyle-limiting symptoms (IC) despite appropriate guideline-directed management and therapy.
  – Duplex ultrasound, magnetic resonance angiography (MRA), and computed tomography angiography (CTA) are recommended in symptomatic patients who are being considered for revascularization (1)[C].
  – Invasive angiography is recommended in patients with critical limb ischemia (1)[B] and is reasonable in those with symptomatic PAD who are candidates for revascularization (1)[C].

Diagnostic Procedures/Other
• Doppler ABI: ratio of systolic BP at the ankle and brachial artery
  – Technique: Obtain BP at dorsalis pedis and posterior tibial arteries while patient is supine and limb is positioned at level of heart. Also obtain BP of both brachial arteries. Then divide higher of the two ankle systolic pressures (dorsalis pedis or posterior tibial) by the higher brachial systolic pressure.
  – ABI ≥1.40 → noncompressible calcified vessel, often seen in CKD, DM, and elderly patients
  – ABI 0.91 to 0.99 → borderline, correlate clinically and consider additional testing
  – ABI ≤0.90, abnormal, diagnostic for PAD
• Leg segmental pressures: obtained after abnormal ABI to localize occlusion and determine treatment plan. A ≤20-mm Hg reduction in pressure is considered significant.
• Toe-brachial index (TBI) is recommended when ABI is ≥1.40, suggesting a noncompressible
The treatment of PAD is multifactorial and includes a supervised exercise program, guideline-based medical therapy, and risk factor modification (2).

An interdisciplinary approach is recommended for optimal treatment, including physicians (vascular specialists if indicated), nurses, exercise physiologists, podiatrists, nutritionists, and social workers.

Supervised exercise training, which takes place in a hospital or outpatient facility, is the initial treatment modality recommended in patients with IC (1)[A]. Patients are instructed to walk for a minimum of 30 to 45 minutes (with rest when symptomatic) 3 times per week for a minimum of 12 weeks.

- A structured community or home-based exercise program can be beneficial and is recommended when a supervised program is not possible (1)[A].

Risk factor modification, most importantly smoking cessation and management of DM, HTN, and HLD:

- Ask about smoking at every visit, counsel on cessation, and offer pharmacologic agents when appropriate (varenicline, bupropion, nicotine replacement therapy) (1)[A].

- Antiplatelet therapy with aspirin or clopidogrel is recommended for patients with PAD when there are no contraindications; however, support for aspirin monotherapy is weak (3)[A]. Studies with aspirin monotherapy have not demonstrated a consistent reduction in fatal or nonfatal cardiovascular events or rates of revascularization. Clopidogrel was shown to have a small relative-risk reduction in ischemic stroke, MI, or vascular death compared to aspirin monotherapy (CAPRIE trial). Benefit must be weighed against harms—particularly risk of gastrointestinal bleeding.

- The use of rivaroxaban (Xarelto) 2.5 mg twice daily with aspirin reduced the composite end point of cardiovascular mortality, MI or stroke, and major adverse limb events compared to aspirin alone (COMPASS trial). However, despite excluding patients with greater bleeding risk, there was a higher rate of major bleeding events in the rivaroxaban (Xarelto) and aspirin group compared to aspirin alone (4).

- High-intensity statin (lipid-lowering therapy) is recommended for all patients with PAD and has been shown to reduce all-cause mortality (1)[A].

- Goal BP <140/90 mm Hg

- ACE-inhibitors are associated with a significant reduction in major adverse cardiovascular events in patients with PAD (1)[A].

**MEDICATION**

**First Line**

- Antiplatelet therapy is recommended in symptomatic PAD without bleeding risk contraindications (3)[A]. Aspirin (75 to 325 mg) or clopidogrel (75 mg) is acceptable first-line antiplatelet agent.

- It is reasonable to prescribe antiplatelet therapy in asymptomatic patients who have an ABI diagnostic of PAD (1)[C].
In asymptomatic patients with borderline ABIs (0.91 to 0.99), the utility of antiplatelet therapy is not well established ([1][B]).

The effect of aspirin on the risk reduction of overall ischemic events remains inconclusive. The Prevention of Progression of Arterial Disease and Diabetes (POPADAD) and Aspirin for Asymptomatic Atherosclerosis (AAA) trials compared low-dose aspirin to placebo in patients with lower ABIs and failed to show a significant reduction in fatal and nonfatal cardiovascular events. However, some studies suggest that aspirin delays disease progression and reduces the need for surgical intervention.

- Dual antiplatelet therapy (DAPT; aspirin and clopidogrel) should be prescribed only following endovascular intervention ([1][C]; the data for efficacy is not well established ([1][B]), and bleeding risk is increased.
- Cilostazol (100 mg orally twice daily) has been shown to improve walking distance and should be considered in all patients with claudication that impacts daily living ([1][C]). However, there is insufficient data on the effect of cilostazol on all-cause mortality or cardiovascular events.

**Second Line**

- Vorapaxar sulfate (Zontivity) (a protease-activated receptor-1 [PAR-1] inhibitor) reduces rates of revascularization and acute limb ischemia, but several studies indicate a major risk of bleeding, including intracranial hemorrhage. Thus, it is not recommended in those with high bleeding risk or with prior CVA, TIA, or intracranial hemorrhage.
- Pentoxifylline (400 mg 3 times daily) was previously considered first line for symptomatic relief of claudication; however, evidence is of poor quality and benefit is uncertain (Cochrane, other reviews).
- Prostaglandins (beraprost, iloprost, cicaprost) are not recommended because they have not shown long-term benefit and are associated with increased adverse events such as headache, nausea, flushing, and diarrhea.

**SURGERY/OTHER PROCEDURES**

Consider endovascular and surgical interventions in select patients who had an inadequate response to less invasive modalities (i.e., exercise and pharmacotherapy), suffer debilitating IC, ischemic rest pain, or tissue loss and have a favorable risk-benefit ratio.

- Beforehand, assess functional status via the Fontaine or Rutherford classification systems. Anatomic classification of complexity is determined by the Trans-Atlantic Inter-Society Consensus (TASC) ([5]).
- Endovascular therapy is rapidly involving and includes angioplasty and stent placement. Balloons and stents can be drug eluting.
  - Preferred for patients with aortoiliac disease ([1][A] and reasonable for femoropopliteal disease ([1][B]
  - Current data are insufficient regarding infrapopliteal lesions, but ongoing studies are comparing efficacy between endovascular and surgical intervention.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Chelation therapy and B-complex vitamins are not recommended in patients with PAD ([1][B]).
- Additional studies on Ginkgo biloba, L-arginine, propionyl-L-carnitine, omega-3 fatty acids, and vitamin E have been studied and, in general, their efficacy is uncertain. Thus, currently they are not recommended for use in the primary care setting.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- At follow-up, patients should undergo thorough history and physical examinations. They should be asked about their progress with risk-factor modification (i.e., smoking, glucose control, HTN), exercise endurance and compliance with training program, and effectiveness of pharmacotherapy.
- After endovascular or surgical intervention, patients should receive regular assessment of symptoms and occlusion via resting and exercise ABIs.

DIET

- A heart-healthy diet is recommended in all patients with PAD or atherosclerotic disease and risk factors.
- Balanced diets consisting of vegetables, fruit, nuts, protein, and healthy fats (such as the Mediterranean diet) are likely best.
- Consultation with a nutritionist can be used in patients when appropriate.

PROGNOSIS

- Limb ischemia and IC: 15–20% will have worsening claudication, 5–10% will require endovascular or surgical intervention, and 2–5% will undergo amputation (most commonly smokers and diabetics).
- Considering cardiovascular outcomes, at 5 years, 20% of patients with PAD will experience a nonfatal cardiovascular event, and 15–20% will die, most commonly of cardiovascular disease.

**CLINICAL PEARLS**
- Consensus on screening for PAD varies. The USPSTF (2013) finds that evidence is insufficient to weigh harms and benefits of screening for PAD.
- The 2016 AHA/ACC guidelines recommend a thorough history, physical exam, and subsequent resting ABI for patients considered at high risk (≥65 years, 50 to 64 years with a risk factor [HTN, HLD, DM, smoking], <50 years with DM and one additional risk factor, or patients at any age with known atherosclerotic disease).
- An interdisciplinary therapeutic approach is recommended. Those who fail noninvasive therapy with a supervised exercise training program and appropriate pharmacotherapy should be referred to vascular surgery for evaluation. Also, patients with an unclear diagnosis or those with CLI (pain at rest, gangrene, ulceration) should be referred.
- Antiplatelet therapy (aspirin or clopidogrel) and cilostazol for symptomatic relief are at the cornerstone of pharmacotherapy. Additionally, appropriate BP control (BP <140/90 mm Hg) and HLD management with statin therapy are indicated in all patients.
- Current studies assessing appropriate screening, optimal pharmacotherapy, and the benefit of endovascular over surgery are underway, suggesting possible improvement of the evidence and guidelines in coming years.
PERITONITIS, ACUTE
Marie L. Borum, MD, EdD, MPH, MACP, FACG, AGAF ●
WonSeok William Choi, BA

BASICS

DESCRIPTION
- Definition: inflammation of the peritoneum
- Classification:
  - Aseptic: chemical irritation or systemic inflammation of peritoneum
  - Bacterial: infection of peritoneal fluid
- Bacterial peritonitis types:
  - Primary/spontaneous bacterial peritonitis (SBP): infection of ascitic fluid in the absence of an intra-abdominal source; typically monomicrobial
  - Secondary bacterial peritonitis: infection of ascitic fluid from a detectable intra-abdominal source (i.e., perforation, abscess); typically polymicrobial
  - Tertiary bacterial peritonitis: persistent infection despite therapy

EPIDEMIOLOGY

Incidence
- In patients with ascites, the annual incidence of SBP is 10–25%.
- Secondary bacterial peritonitis correlates with underlying pathology (e.g., colitis, appendicitis, diverticulitis, peptic ulcer disease).
- 57% of patients with secondary bacterial peritonitis progress to tertiary peritonitis.

Prevalence
- SBP: In asymptomatic patients with cirrhosis and ascites, the prevalence is <3% in outpatients. Nosocomial rates are 8–36%.
- In patients with cirrhosis and ascites, 5% of peritonitis is secondary.

ETIOLOGY AND PATHOPHYSIOLOGY

- Mechanism
  - SBP:
    - Bacterial translocation via lymphatic spread through mesenteric lymph nodes
    - Usually develops in the setting of large-volume ascites in patients with advanced cirrhosis
    - Cirrhotic patients have:
      - Alterations to gut microbiota with higher prevalence of pathogenic organisms
      - Small intestinal bacterial overgrowth (SIBO) and increased intestinal mucosal permeability to bacteria
      - Decreased cellular and humoral immunity limiting peritoneal bacterial clearance
  - Secondary bacterial peritonitis
    - Spillage/translocation of bacteria from inflamed or perforated intraperitoneal organs or introduction of bacterial through instrumentation—including peritoneal dialysis, intraperitoneal chemotherapy
  - Tertiary bacterial peritonitis
Evolves from secondary peritonitis with inadequate source control

- Peritoneal dialysis-related peritonitis (PD peritonitis)
- Contamination with pathogenic skin flora during exchanges or exit-site infection
  - Intraluminal contamination: most common source of infection; associated with lack of appropriate sterile technique for connecting catheter and frequency of exchange
  - Periluminal contamination: extension of bacteria from exit-site or tunnel infection
  - Visceral contamination: due to gut flora

**Microbiology**

- SBP. Most cases (>90%) of SBP are mono-microbial.
  - Escherichia coli (33%), Streptococcus spp. (15%), Staphylococcus (13%), Klebsiella (8%); reflects increasing rate of gram-positive and resistant organisms (e.g., extended-spectrum β-lactamase [ESBL]–producing E. coli, MRSA, Enterococcus) in the nosocomial setting (1)
- Secondary bacterial peritonitis. Second most common cause of sepsis in ICU patients. Can be due to perforation of a viscus, small bowel strangulation, necrotizing pancreatitis. Organism depends on site of underlying pathology. Gram positive organisms more common with upper GI pathology. Gram negative organisms more common with lower GI pathology (and/or patients on chronic PPI therapy).
  - E. coli, Klebsiella, Proteus, Streptococcus, Enterococcus, Bacteroides, Clostridium
- PD peritonitis
  - Most commonly due to Staphylococcus epidermidis and Staphylococcus aureus
  - Also by gram-negative organisms and fungi

**RISK FACTORS**

- SBP: advanced cirrhosis with ascites, malnutrition, upper GI bleed, PPI usage, prior SBP
  - Acid suppression (most commonly with PPIs) promotes SIBO increasing incidence of SBP. Hospitalized cirrhosis patients receiving PPIs are at increased risk for SBP (1).
  - 70% of SBP cases are in patients with Child-Pugh class C cirrhosis.
  - Low ascites protein (<1.0 g/dL) increases risk.
  - Factors associated with perforation or fluid translocation (e.g., peritoneal dialysis, Helicobacter pylori and NSAIDs causing ulcers, vascular disease causing bowel ischemia, alcohol abuse causing pancreatitis)
- PD peritonitis
  - Recent instrumentation involving GI/GU tract (e.g., colonoscopy, cystoscopy, dental procedures)
  - Nasal Staphylococcus aureus carriage
  - Underlying GI pathology

**GENERAL PREVENTION**

- SBP prophylaxis in patients at high risk (e.g., ascitic fluid protein concentration <1.0 g/dL, esophageal varices, history of previous SBP)
  - Prior SBP: prophylactic norfloxacin or sulfamethoxazole and trimethoprim (Bactrim) PO daily
  - Cirrhosis and GI bleed: 7-day course of ceftriaxone 1 g IV daily or norfloxacin BID; IV while bleeding, PO as tolerated. IV ceftriaxone is superior to oral norfloxacin.
  - Cirrhotic ascites: low ascitic fluid protein (<1.5 g/dL) with renal impairment (creatinine ≥1.2, BUN ≥25, or serum Na ≤130) or liver failure (child score ≥9, bilirubin ≥3):
prophylactic norfloxacin or sulfamethoxazole and trimethoprim (Bactrim) PO daily

- Limit use of PPIs.

- PD peritonitis
  - Proper training in sterile techniques
  - Antibiotic prophylaxis prior to selected procedures
  - Drainage of peritoneal fluid prior to procedures

## DIAGNOSIS

### HISTORY

- SBP: history of cirrhosis or ascites, fever, chills, mental status changes, abdominal pain (diffuse, continuous; may be subtle due to presence of ascites), nausea/vomiting, diarrhea, GI bleed
- Secondary bacterial peritonitis: may be clinically indistinguishable from SBP unless history of perforation, abscess, or peritoneal dialysis is present
- Tertiary: persistent signs and symptoms despite initial treatment or history of recurrent peritonitis
- PD peritonitis: cloudy effluent + symptoms of SBP

### ALERT

30% of patients are asymptomatic.

### PHYSICAL EXAM

- Tachycardia, fever, tachypnea, altered mental status, hypotension, hypothermia
  - AMS may be subtle; Reitan trail test (connect-the-numbers test) helpful in detecting subtle changes in mental status.
  - Suspect AMS if the number of seconds it takes for patient to finish test is greater than his/her age.
- Abdominal distention, ascites, abdominal wall guarding, rebound tenderness, hypoactive/absent bowel sounds
  - There is no rigidity because ascites separates parietal layer of peritoneum from visceral layer.

### DIFFERENTIAL DIAGNOSIS

- Liver disease: hepatitis, decompensated cirrhosis
- Luminal disease: abscess formation, ileus, volvulus, intussusception, mesenteric adenitis, pancreatitis, cholecystitis, malignancy, peritoneal carcinomatosis
- Extraluminal disease: ruptured ectopic pregnancy, tubo-ovarian abscess, PID, UTI, and/or pyelonephritis
- Systemic disease: tuberculosis, pneumonia, MI, porphyria, SLE

### DIAGNOSTIC TESTS & INTERPRETATION

**Initial Tests (lab, imaging)**

### ALERT

Early diagnosis reduces mortality.
Immediate evaluation

**ALERT**
Ascitic fluid culture can be negative in up to 50% of patients with SBP.

- Paracentesis, blood, and urine cultures before antibiotics. Broad-spectrum antibiotics decrease ascitic culture yield (even a single dose).
- Ascitic fluid studies: culture, Gram stain, cell count with differential, and albumin; for secondary peritonitis, include LDH, total protein, glucose, alkaline phosphatase (ALP), and CEA.
- SBP: PMN >500 cells/mm$^3$ in ascitic fluid is best individual predictor of SBP (86% sn; 98% specific). A cutoff of 250 cells/mm$^3$ has sensitivity of 93% and specificity of 94%.
- Secondary peritonitis: PMN >250 cells/mm$^3$ on ascitic fluid analysis (usually thousands), with the following:
  - Polymicrobial culture or two of: ascitic fluid total protein >1 g/dL, glucose <50 mg/dL, LDH >225 mU/mL; more sensitive for cases of perforation (96%) than nonperforation (50%)
  - Secondary peritonitis with perforation is likely with ALP >240 U/L or CEA >5 ng/mL, sensitivity 92%; not useful for detection of nonperforation secondary peritonitis
- PD peritonitis: positive fluid culture or clinical features + peritoneal fluid WBC > 100 with PMN > 50%
- CT scan is often not diagnostic for secondary peritonitis.
  - Abdominal or chest x-ray may show free air in peritoneal cavity, large/small bowel dilatation, intestinal wall edema in secondary peritonitis.

**Follow-Up Tests & Special Considerations**
- If asymptomatic bacterascites, recent antibiotic exposure, nosocomial atypical organism, or no clinical improvement, repeat paracentesis in 48 hours to determine resolution (decrease in PMNs of 25% or negative cultures).
- In hemorrhagic ascites, PMN count is corrected by subtracting 1 PMN per 250 RBCs.
- Procalcitonin levels may predict severity in cases of secondary peritonitis.

**Diagnostic Procedures/Other**
PMN > 250 cells/mm$^3$ and a positive culture confirm the diagnosis of SBP.

**TREATMENT**

**GENERAL MEASURES**
- For SBP, control ascites with salt restriction, spironolactone ±, furosemide, albumin infusion after large volume paracentesis, and/or lactulose for encephalopathy.
- Avoid nephrotoxic medications and other renal insults (1)[C].

**MEDICATION**
- SBP
  - Community-acquired SBP without recent β-lactam antibiotic use: 3rd-generation cephalosporins, preferably cefotaxime, 2 g IV q8h for 5 days
  - SBP in absence of previous quinolone use/prophylaxis, vomiting, shock, hepatic
encephalopathy, or serum creatinine >3 mg/dL: can substitute ofloxacin 400 mg PO for cefotaxime
– Nosocomial SBP or recent β-lactam antibiotic: empiric therapy based on local susceptibility of patients with cirrhosis for resistant bacteria
– Symptomatic bacterascites with PMN count <250 cells/mm³: cefotaxime 2 g IV q8h while awaiting sensitivities
– Second-line antibiotics include fluoroquinolones (levofloxacin), piperacillin/tazobactam, or vancomycin (1)[B]
  o Ciprofloxacin 400 mg IV BID can be used in patients for whom cephalosporin is contraindicated or poorly tolerated
– SBP with renal or hepatic impairment (serum creatinine >1 mg/dL, BUN >30 mg/dL, or total bilirubin >4 mg/dL): Add albumin 1.5 g/kg within 6 hours and 1 g/kg on day 3.
– Most patients respond well to 5-day course of parenteral antibiotics.
  o Longer therapy is considered for patients infected with:
    ■ Unusual organism (e.g., Pseudomonas)
    ■ Organism resistant to standard antibiotic regimen
    ■ Organism associated with infectious endocarditis (e.g., viridans Streptococci)
  – Reassess patient after 5-day antibiotic course.
  o If asymptomatic, no further treatment is needed
  o If fever or pain persists, repeat paracentesis
    ■ If PMN <250, no further treatment is needed
    ■ If PMN <pre-treatment level but >250, continue antibiotic for additional 48 hours followed by repeat paracentesis
    ■ If PMN >pre-treatment level, search for surgical source of infection

● Secondary bacterial peritonitis
  – Empiric broad-spectrum antibiotic coverage for polymicrobial infection; IV cefotaxime or other 3rd- to 4th-generation cephalosporin plus metronidazole is an initial option.

● Tertiary bacterial peritonitis
  – If no unrepaired perforations or leaks, continue with medical management: Antibiotics (guided by susceptibilities) and early enteral nutrition prevent atrophy and maintain immunocompetence.
  – Consider removing catheter if recurrent or persistent peritoneal dialysis–associated infection.

● PD peritonitis
  – Intraperitoneal preferred over IV unless patient is septic.
  – Antibiotic can be give intermittently or continuously.
  – Gram-positive coverage: vancomycin or 1st generation cephalosporin (e.g., cefazolin)
  – Gram-negative coverage: 3rd or 4th generation cephalosporin (e.g., ceftazidime, cefepime), aminoglycoside, aztreonam
  – Treat for 3 weeks except coagulase-negative Staphylococci and Streptococci (2 weeks)
  – Anaerobe and enteric Gram-negative rod coverage: metronidazole + vancomycin + aminoglycoside/ceftazidime
  – Polymicrobial: infection with multiple Gram-negative organisms should raise suspicion about intra-abdominal pathology. Consider imaging and surgical consultation.
  – Culture-negative: both Gram-positive and Gram-negative, repeat cell count and culture in 3 days.
Most patients usually improve within 48 hours of initiation of antibiotic therapy.
  - Clinical improvement, less cloudy efferent, and/or lower cell count in peritoneal fluid
  - If lack of improvement, can increase dose or switch from intermittent to continuous administration
PD is not discontinued in PD peritonitis
Remove catheter if:
  - Fungal or mycobacterial peritonitis
  - Culture-negative peritonitis with persistent symptoms and elevated WBC in peritoneal fluid
  - Peritonitis not responding after a 5-day course of antibiotics
  - Peritonitis recurring within 4 weeks of completion of antibiotic course

SURGERY/OTHER PROCEDURES
- SBP
  - Medical management
- Secondary bacterial peritonitis
  - Emergent surgical management, including source control with open laparotomy to repair any perforated viscus and eradicate infected material, is first-line treatment.
- Tertiary bacterial peritonitis
  - If no unrepaired perforations or leaks, additional surgery for severe abdominal infection correlates with deterioration and mortality.

ALERT
The mortality of secondary bacterial peritonitis approaches 100% if not treated surgically.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Acute peritonitis typically warrants hospitalization.
- In patients with cardiogenic or septic shock, use invasive monitoring with goal-directed fluid therapy.
- Patients who present with peritonitis can be severely hypovolemic, and volume resuscitation is critical. In patients with significant renal or hepatic dysfunction, albumin decreases mortality.
- Cirrhotic patients are often on β-blockers. During an episode of SBP, β-blockers increase mortality, hepatorenal syndrome, and hospital stay.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Normalization of vital signs with resolution of leukocytosis is a sign of improvement.
- PMN decrease >25% is expected if follow-up paracentesis is performed after 48 hours.

DIET
- NPO, total parental nutrition as necessary
- Resume enteral feeding after return of bowel function.
- Sodium restriction can reduce future ascites.

PROGNOSIS
● SBP
  – For inpatients with first episode of SBP, mortality ranges from 10% to 50%.
  – Prognosis improves if antibiotics are started early, prior to onset of shock or renal failure.
  – Renal insufficiency is the strongest negative prognostic indicator.
  – Other poor prognostic factors include nosocomial acquisition, old age, high Child-Pugh-Turcotte or MELD score, malnutrition, ileus, hypotension, hypothermia, malignancy, peripheral leukopenia, and antibiotic resistance.
  – Patients with prior SBP have 1-year recurrence of 40–70% and 1-year mortality of 31–93%.
● Secondary bacterial peritonitis:
  – In-hospital mortality of treated patients is 67%.
  – Mortality approaches 100% if not treated surgically, especially with perforation.
  – Prognosis is worse in perforated etiologies.
● PD peritonitis
  – 2–6% mortality (highest in fungal, Gram-negative, and Staphylococcus aureus infection)
  – 5–20% switch to hemodialysis

COMPLICATIONS
● Renal and hepatic failure, encephalopathy, coagulopathy
● Secondary infection, iatrogenic infection, abscess, fistula formation, abdominal compartment syndrome
● Sepsis/septic shock, cardiovascular collapse, adrenal insufficiency, respiratory failure, ARDS

REFERENCES

SEE ALSO
Appendicitis, Acute; Cirrhosis of the Liver; Diverticular Disease; Peptic Ulcer Disease

CODES
ICD10
● K65.0 Generalized (acute) peritonitis
● K65.2 Spontaneous bacterial peritonitis
● K65.8 Other peritonitis

CLINICAL PEARLS
● Maintain a high index of suspicion for SBP in cirrhotic patients with ascites (up to 30% of cases may be asymptomatic). Start empiric therapy early.
● SBP is usually monomicrobial. Paracentesis is necessary to diagnose
● E. coli is the most common bacterial isolate from cases of SBP. 3rd-generation cephalosporins are first-line treatment.
- Ascitic fluid analysis stratifies patients at risk for secondary peritonitis who need additional imaging.
- Renal function is an important prognostic indicator for SBP.
PERTUSSIS
Mary Cataletto, MD, FAAP, FCCP ● Margaret J. McCormick, MS, RN, CNE

BASICS
- Highly contagious
- Synonym: whooping cough, “100 day” cough

DESCRIPTION
- Host: humans
- Most common reservoir: adults
- Ages: all
- Distribution: worldwide
- Pattern: endemic or epidemic with outbreaks every 3 to 5 years
- Seasonality: can occur year-round; peaks late summer–autumn
- Transmission: person to person via aerosolized respiratory droplets
- Effective vaccine: available
- Immunity: neither 100% nor lifelong immunity with either infection or vaccine
- System(s) affected: respiratory

EPIDEMIOLOGY
Incidence
- Worldwide: 24.1 million cases (1)
- 160,700 deaths in children <5 years old (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Toxin mediated
- Infectious process with predilection for ciliated respiratory epithelium
- Common organisms:
  - Bordetella pertussis (accounts for ~95% of cases)
  - Bordetella parapertussis

RISK FACTORS
- Exposure to a confirmed case
- Non- or underimmunized infants and children
- Premature birth
- Chronic lung disease
- Immunodeficiency (e.g., AIDS)
- Age <6 months (accounts for ~90% pediatric pertussis hospitalizations) (2)

GENERAL PREVENTION
- Public health measures
  - Surveillance
  - Outbreak management
  - Care of exposed persons
Prevention programs

Immunization
- Primary childhood immunization series against pertussis followed by boosters (3)
- Maternal immunization during each pregnancy (4,5,6)
- Adults, including health care providers in close contact with infants <1 year of age, should be immunized.

Pediatric Considerations
Strategies to reduce neonatal pertussis:
- Tdap with each pregnancy, preferably between 27 and 36 weeks’ gestation (4,5,6)
- Cocooning (6)
- Tdap recommended for all persons in close contact with infants <1 year of age

Geriatric Considerations
The incidence of pertussis in individuals age 50 years and older has increased between 2006 and 2010.

COMMONLY ASSOCIATED CONDITIONS
- Apnea in infants
- Secondary bacterial pneumonia
- Sinusitis
- Seizures
- Encephalopathy
- Urinary incontinence

DIAGNOSIS

HISTORY
- Exposure to pertussis
- Insidious onset
- Incubation period 7 to 10 days (ranges 5 to 21 days)

PHYSICAL EXAM
- Classic pertussis has three phases, which occur over 6 to 10 weeks:
  - Catarrhal phase: rhinorrhea, mild cough, low-grade fever
  - Paroxysmal phase: Cough occurs in bursts, with increased intensity and frequency, often followed by an inspiratory whoop and/or posttussive vomiting.
  - Convalescent phase: Coughing paroxysms decrease in frequency and intensity.
- In the absence of paroxysms or complications, the physical exam may be normal.
- Classic presentation more common in adults

ALERT
Infants <6 months of age may have atypical presentations.

DIFFERENTIAL DIAGNOSIS
Sporadic, prolonged cough can also be caused by (7):
- B. parapertussis
- Mycoplasma pneumoniae
Chlamydia trachomatis
Chlamydophila pneumoniae
Bordetella bronchiseptica
Bordetella holmesii
Respiratory syncytial virus
Adenovirus

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Nasopharyngeal culture (gold standard): best results within 2 weeks of cough onset (7)[A]
- False results can occur in:
  - Previously immunized individuals
  - After initiation of appropriate antibiotic
  - After 2 weeks from cough onset
  - With incorrect collection or handling
- Polymerase chain reaction (PCR) assays: rapid turnaround time; good within first 3 weeks (7)[C]
- Serology:
  - Commercially available assays
  - Not FDA-approved for diagnosis

Follow-Up Tests & Special Considerations
- Evaluation and follow-up for associated conditions and complications
- Chest radiograph (two views) to evaluate for the presence of pneumonia
- EEG/neuroimaging may be considered in infant with seizures or apparent life-threatening events (ALTEs).
- Infants <1 month of age who are treated with macrolides should be monitored for the possible development of hypertrophic pyloric stenosis.

TREATMENT

GENERAL MEASURES
Waiting rooms, during transport, and procedures: Patients with suspected pertussis should wear masks.

MEDICATION
- Start empiric antibiotic therapy once diagnostic testing is performed in cases with strong clinical suspicion or in those at high risk for complications.
- Antibiotic therapy after cough is established may help to limit spread but is not expected to change clinical symptoms.
- Preferred antibiotics:
  - For patients >6 months:
    o Azithromycin, clarithromycin, or erythromycin
  - For infants <1 month of age, azithromycin preferred but with caution

First Line
Azithromycin is the first line for treatment and for postexposure prophylaxis (5-day course) (7)
Infantile hypertrophic pyloric stenosis has been associated with the use of macrolides in infants ≤1 month of age. Consultation and monitoring are recommended.

**ALERT**
Fatal cardiac dysrhythmias have been reported with azithromycin. Caution recommended in individuals with prolonged QT and proarrhythmic conditions.

**Second Line**
Trimethoprim/sulfamethoxazole (TMP/SMX) (for persons >2 months of age) if:
- Macrolide intolerance
- Macrolide resistance

**ALERT**
- TMP/SMX is contraindicated in infants <2 months of age.
- Clarithromycin is not recommended in infants <1 month of age.

**ISSUES FOR REFERRAL**
Evaluation and treatment of infants <6 months of age, especially those born prematurely, who are unimmunized and those who require hospitalization.

**ADDITIONAL THERAPIES**
Symptomatic treatment of the cough in pertussis (e.g., corticosteroids, β₂-adrenergic agonists, pertussis-specific immunoglobulin, antihistamine, and leukotriene receptor antagonist) has not shown consistent benefit.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Small, frequent meals may be necessary to ensure adequate nutrition.
- IV fluids indicated for dehydration and when oral fluids are either contraindicated or poorly tolerated.
- In addition to standard precautions, hospitalized patients should be isolated with respiratory precautions for 5 days after the initiation of effective antibiotic treatment and for 3 weeks after onset of paroxysms in older patients if antibiotics are not used.
- Gentle suctioning of nasal secretions.
- Avoid stimuli that trigger paroxysms.
- Respiratory monitoring, including pulse oximetry.
- Educate each family about the importance of immunizations.
- Discuss chemoprophylaxis with each family.
- Discharge criteria
  - Clinically stable
  - Able to tolerate oral feedings

**ONGOING CARE**
Supportive
FOLLOW-UP RECOMMENDATIONS
- Monitor infants who received EES or azithromycin for pyloric stenosis.
- Neurologic and/or pulmonary follow-up as necessary

Patient Monitoring
ICU care may be necessary for severely ill or compromised patients.

DIET
IV fluids/nutrition may be required to treat dehydration or supplement poor oral intake.

PATIENT EDUCATION
- Centers for Disease Control and Prevention: http://www.cdc.gov

PROGNOSIS
- Complete recovery in most cases
- Most severe morbidity and highest mortality in infants <6 months of age
- Overall mortality approximately 195,000/year (1)

COMPLICATIONS
- Highest and most severe in infants; may include apnea, cyanosis, and sudden death
- In children: may include conjunctival hemorrhage, inguinal hernia, pneumonia, and seizures
- More frequent in adults than adolescents: may include sinusitis, otitis media, pneumonia, weight loss, fainting, rib fracture, urinary incontinence, seizures, encephalopathy, and death

REFERENCES

ADDITIONAL READING
- Centers for Disease Control and Prevention. Diagnosis confirmation.

**CODES**

**ICD10**

- A37.90 Whooping cough, unspecified species without pneumonia
- A37.80 Whooping cough due to other Bordetella species w/o pneumonia
- A37.10 Whooping cough due to Bordetella parapertussis w/o pneumonia

**CLINICAL PEARLS**

- Hospitalizations for pertussis is highest in infants <6 months of age.
  - Maternal Tdap is effective in protecting young infants against pertussis, especially during first 2 months of life.
- Neither immunization nor active infection confers lifelong immunity.
PHARYNGITIS
Pratha Muthiah, MD, MPH ● Jason Chao, MD, MS

BASICS

DESCRIPTION
- Acute or chronic inflammation of the pharyngeal mucosa and underlying structures of the throat
- Group A Streptococcus (GAS) pharyngitis is notable for preventable suppurative (e.g., retropharyngeal or peritonsillar abscess) and nonsuppurative (e.g., rheumatic sequelae) complications.
- Synonym(s): sore throat; tonsillitis; “strep throat”

EPIDEMIOLOGY
- ~15 million cases are diagnosed yearly.
- Accounts for 1–2% of all outpatient visits and 6% of all pediatric visits to primary care physicians
- Most commonly viral (40–60%)
- GAS is the most common bacterial cause of acute pharyngitis, accounting for 15–30% of pediatric and 5–15% of adult cases. The incubation period ranges from 24 to 72 hours.
- Rheumatic fever is rare in the United States (<1 per 100,000). Early antibiotic use has diminished occurrence.
- 3,000 to 4,000 patients with group A β-hemolytic streptococcal infection must be treated to prevent one case of acute rheumatic fever.
- Affects all age groups, some etiologies and sequelae occur more frequently in certain age groups

Pediatric Considerations
The highest incidence of rheumatic fever is in children 5 to 18 years as a rare sequela of streptococcal pharyngitis.

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute, viral (associated with lower grade fever)
  - Rhinovirus; Adenovirus (associated with conjunctivitis); Parainfluenza virus;
    Coxsackievirus (hand-foot-mouth disease); Coronavirus; Echovirus
  - Herpes simplex virus (vesicular lesions); Epstein-Barr virus (EBV/mononucleosis);
    Cytomegalovirus (CMV)
  - HIV
- Acute, bacterial (associated with higher fevers)
  - Group A β-hemolytic Streptococcus
  - Neisseria gonorrhoeae; Corynebacterium diphtheriae (diphtheria); Haemophilus influenzae
  - Moraxella catarrhalis; Chlamydia pneumonia
  - Fusobacterium necrophorum (20% young adult cases); Group C or G Streptococcus
  - Arcanobacterium haemolyticum; Mycoplasma pneumoniae; Francisella tularensis (tularemia)
- Acute, noninfectious
Various caustic, mechanical, or trauma-related (including endotracheal intubation)
- Chronic
  - More likely noninfectious
  - Chemical irritation (GERD)
  - Smoking
  - Neoplasms
  - Vasculitis
  - Radiation changes

**Genetics**
Patients with a family history of rheumatic fever have a higher risk of rheumatic sequelae following an untreated group A β-hemolytic streptococcal infection.

**RISK FACTORS**
- Epidemics of group A β-hemolytic streptococcal disease
- Cold and flu season (late fall through early spring)
- Age (rheumatic fever possible, especially in children/adolescents 5 to 15 years)
- Close contact with infected individuals (home, daycare, military barracks)
- Immunosuppression
- Smoking/secondhand smoke exposure
- Acid reflux
- Oral sex
- Diabetes mellitus
- Recent illness (secondary postviral bacterial infection)
- Chronic colonization of bacteria in tonsils/adenoids

**GENERAL PREVENTION**
- Avoid close contact with infectious patients.
- Wash hands frequently.
- Avoid first or secondhand smoke.
- Manage preventable causes (e.g., GERD).

**DIAGNOSIS**

**HISTORY**
- Sore throat
- Difficulty swallowing (dysphagia) or pain on swallowing (odynophagia)
- Cough (uncommon in GAS pharyngitis)
- Hoarseness; “hot potato” voice
- Fever
- Anorexia
- Chills
- Malaise; fatigue
- Headache
- Dysuria and arthralgias (suggest gonococcal etiology)
- Sick contacts with similar symptoms or confirmed diagnosis
PHYSICAL EXAM
- Enlarged tonsils with or without exudate
- Pharyngeal erythema; palatal petechiae
- Unilateral tonsillar swelling (“frog’s belly”) or uvular deviation (concern for peritonsillar abscess)
- Trismus; stridor; drooling (concern for peritonsillar or retropharyngeal abscess)
- Cervical adenopathy (anterior suggestive of GAS, posterior most commonly associated with infectious mononucleosis)
- Fever (higher in bacterial infections)
- Pharyngeal ulcers (CMV, HIV, Crohn, other autoimmune vasculitides)
- Scarlet fever rash: Punctate erythematous macules with reddened flexor creases and circumoral pallor suggests streptococcal pharyngitis.
- Tonsillar/soft palate petechiae with hepatosplenomegaly suggest infectious mononucleosis (EBV/CMV).
- Gray oral pseudomembrane suggests diphtheria and occasionally infectious mononucleosis (EBV/CMV).
- Characteristic erythematous-based clear vesicles suggest HSV or coxsackie A virus infection (herpangina).
- Conjunctivitis suggests adenovirus.

DIFFERENTIAL DIAGNOSIS
- Viral infection
- Streptococcal infection
- Allergic rhinitis/postnasal drip
- GERD
- Malignancy (lymphoma or squamous cell carcinoma)
- Irritants/chemicals (detergent/caustic ingestion)
- Atypical bacterial (e.g., gonococcal, chlamydial, syphilis, pertussis, diphtheria)
- Oral candidiasis (patients typically complain mostly of dysphagia)
- Thyroiditis (can be painful or painless, possibly associated with hyperthyroid syndrome)
- Epiglottitis (associated with stridor, drooling, and progressive respiratory distress)

DIAGNOSTIC TESTS & INTERPRETATION
- Prediction rules determine need for further testing (see below).
- Additional testing generally not needed if viral-like clinical features (e.g., cough, rhinorrhea, hoarseness, oral ulcers, diarrhea, conjunctivitis, rash) (1)[A]
- Avoid testing for GAS pharyngitis in children <3 years as acute rheumatic flare is rare, unless there is a close sick contact who is GAS-positive (1)[B].
- Modified Centor clinical prediction rule for group A streptococcal infection (2)[A]:
  - +1 point: tonsillar exudates
  - +1 point: tender anterior chain cervical adenopathy
  - +1 point: absence of cough
  - +1 point: fever by history
  - +1 point: age <15 years
  - 0 point: age 15 to 45 years
  - −1 point: age >45 years
- Scoring:
– If 4 points, positive predictive value of ~80%; treat empirically.
– If 2 to 3 points, positive predictive value of ~50%, rapid strep antigen; treat if GAS-positive.
– If 0 or 1 point, positive predictive value <20%; do not test; treat symptomatically with follow-up as needed.

Initial Tests (lab, imaging)

- Testing, if performed, is usually for GAS. Options include:
  - Rapid antigen streptococcus test (RAST); quick adjunct to throat culture with 96% specificity and 86% sensitivity (although sensitivity varies by modality kit) (3)[A]
  - Blood agar throat culture from swab; gold standard—90–95% sensitivity (3)[A]
    - Back-up throat cultures are not needed for adults with negative RAST. They are recommended for children with negative RAST due to the higher likelihood of complications but can be omitted if a highly sensitive immunoassay or molecular test was used.
  - Antistreptolysin O (suspect carrier state if positive culture, and unchanged ASO titers)

- Special tests if history suggests a different diagnosis
  - Warm Thayer-Martin plate or antigen testing for N. gonorrhoeae
  - Viral cultures for HSV
  - Monospot for EBV
  - IgM serology for CMV

Follow-Up Tests & Special Considerations

Recurrent GAS infection may indicate beta-lactamase production by host, may require antibiotic with anti-beta-lactamase activity

Test Interpretation

Bacitracin disk sensitivity of hemolytic colonies suggests group A β-hemolytic Streptococcus.

**TREATMENT**

Treatment is largely for symptomatic relief, unless bacterial infection is confirmed or highly suspected.

**GENERAL MEASURES**

Conservative therapy recommended for most cases (unless bacterial etiology suspected):

- Salt water gargles
- Acetaminophen 10 to 15 mg/kg/dose q4h PRN pain or fever (pediatric). In adults, do not exceed >3 g/day.
- Non-steroidal anti-inflammatory drugs (NSAIDs) for pain or fever (more effective than acetaminophen for GAS pharyngitis)
- Anesthetic lozenges
- Cool-mist humidifier
- Hydration (PO or IV if PO is not tolerated)
- Viscous lidocaine (2%) 5 to 10 mL PO q4h swish/spit (severe pain)

**Pediatric Considerations**
Opioids not recommended due to black box warnings
Lower threshold to start antibiotics due to higher risk of rheumatic fever
Avoid aspirin for symptom relief in pediatric patients due to risk of Reye syndrome

MEDICATION
Antibiotics (particularly penicillin) are used primarily to prevent complications.
- 60–70% primary care visits by children with pharyngitis result in antibiotic prescriptions
  (4). Empiric therapy results in antibiotic overuse.
- Treatment duration generally 10 days (1)[A]
- Antibiotics do not reduce risk of poststreptococcal glomerulonephritis.
- Antibiotics shorten duration of symptoms by approximately 16 hours (5).
- Antibiotics may prevent pharyngitis/fever by day 3 (NNT 4 if GAS-positive, 6.5 if GAS-negative, 14.4 if untested) (5)[A].

Ulcers related to autoimmune diseases usually require systemic or intralesional injectable steroids.
HIV-related ulcers are due to decreasing counts of CD4 and respond when patients’ CD4 titers increase.
Corticosteroids, when used concomitantly with antibiotics, may provide a small reduction in the duration of symptoms (24 hours). Routine use is not currently recommended (1)[B],[3][B].

First Line
Recommended first-line therapies (1)[A]:
- Penicillin V: children (<27 kg): 250 mg PO TID (BID dosing sufficient if good compliance);
  adolescents and adults (>27 kg): 250 mg PO QID or 500 mg PO BID
- Penicillin G benzathine: children <60 lb (27 kg): 600,000 units intramuscularly 1 dose;
  children ≥60 lb and adults: 1.2 million units intramuscularly 1 dose
- Amoxicillin: 50 mg/kg PO once daily (max 1,000 mg/dose or 25 mg/kg PO BID (max = 500 mg/dose)

ALERT
Use with caution if diagnosis is unclear because using amoxicillin with EBV infection may induce rash.

Second Line
- If type IV hypersensitivity but no history of anaphylactic penicillin allergy:
  - Cephalexin 20 mg/kg PO BID or (children) 25 to 50 mg/kg/day divided BID or (adults)
    1,000 mg PO QID (max = 4 g/day)
  - Cefadroxil 30 mg/kg PO once daily (max = 1 g/day)
- If history of anaphylactic penicillin allergy (type I hypersensitivity):
  - Azithromycin 12 mg/kg PO once daily for 5 days (max = 500 mg/dose)
  - Clarithromycin 7.5 mg/kg PO BID (max = 250 mg/dose) or (adults) 250 to 500 mg PO BID
  - Clindamycin 7 mg/kg PO TID (max = 300 mg/dose) or (children) 10 to 30 mg/kg/day PO
    divided TID–QID or (adults) 150 to 450 mg PO TID–QID
- Penicillin is most commonly used to prevent rheumatic sequelae; cephalosporins have a lower rate of antimicrobial failure for streptococcal pharyngitis.
- Newer macrolides are effective against streptococcal pharyngitis; they are also more expensive and unproven at preventing rheumatic complications.
- Macrolide-resistant strains of GAS are currently <10% in the United States but more prevalent
ISSUES FOR REFERRAL
- Document each GAS-confirmed episode to support the need for future tonsillectomy and adenoidectomy.
- Tonsillectomy is recommended for patients who have had seven or more throat infections (viral or bacterial) in 1 year, five or more infections per year for the past 2 years, or three or more infections per year for the past 3 years. Tonsillectomy is also recommended in patients who are difficult to treat medically, including those who are allergic to multiple antibiotics.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Complete the full course of antibiotic therapy, regardless of symptom response.
- Patients are generally noninfectious after 24 hours of antibiotics.
- Follow-up culture for GAS is not recommended ([1][A]).

DIET
As tolerated. Encourage the consumption of fluids.

PROGNOSIS
- Streptococcal pharyngitis runs a 5- to 7-day course with peak fever at 2 to 3 days.
- Symptoms will resolve spontaneously without treatment, but rheumatic complications are still possible.

COMPLICATIONS
- Rheumatic fever (e.g., carditis, valve disease, arthritis)
- Poststreptococcal glomerulonephritis
- Peritonsillar abscess (a.k.a. quinsy tonsillitis): considered a clinical diagnosis and does not warrant ultrasound/computed tomography. Will generally require percutaneous/transoral drainage. Surgery may also involve a quinsy (acute) tonsillectomy. Most sources recommend resolution of the acute infection before surgery.
- Acute airway compromise (rare) can typically be bypassed with nasal trumpets. Consult anesthesiologist/otolaryngologist.
- Repeated episodes of GAS pharyngitis may represent recurrent viral infections in a chronic pharyngeal GAS carrier ([1][B]). IDSA recommends against repeated diagnostic efforts/antibiotic therapy in a known chronic pharyngeal GAS carrier, as they are seldom contagious or at risk for serious complications.

REFERENCES

ADDITIONAL READING

SEE ALSO
- Herpes Simplex; Infectious Mononucleosis, Epstein-Barr Virus Infections; Rheumatic Fever
- Algorithm: Pharyngitis

CODES

ICD10
- J31.1 Chronic nasopharyngitis
- A54.5 Gonococcal pharyngitis
- B08.5 Enteroviral vesicular pharyngitis

CLINICAL PEARLS
- Most cases of pharyngitis are viral and do not require antibiotics.
- The risk associated with undiagnosed and untreated group A streptococcal infection is for rheumatic sequelae—a rare complication.
- Use of the Modified Centor Score helps to guide testing and treatment.
- Penicillin is the preferred first-line therapy for group A streptococcal infection.
BASICS

DESCRIPTION
- Pilonidal disease results from an abscess, or sinus tract, in the upper part of the natal (gluteal) cleft.
- Synonym(s): jeep disease

EPIDEMIOLOGY

Incidence
- 16 to 26/100,000 per year
- Predominant sex: male > female (3 to 4:1)
- Predominant age: 2nd to 3rd decade, rare >45 years
- Ethnic consideration: whites > blacks > Asians

Prevalence
Surgical procedures show male: female ratio of 4:1, yet incidence data are 10:1.

ETIOLOGY AND PATHOPHYSIOLOGY

- Pilonidal means “nest of hair”; hair in the natal cleft allows hair to be drawn into the deeper tissues via negative pressure caused by movement of the buttocks (50%); follicular occlusion from stretching and blocking of pores with debris (50%)
- Inflammation of SC gluteal tissues with secondary infection and sinus tract formation
- Polymicrobial, likely from enteric pathogens given proximity to anorectal contamination

Genetics
- Congenital dimple in the natal cleft/spina bifida occulta
- Follicular-occluding tetrad: acne conglobata, dissecting cellulitis, hidradenitis suppurativa, pilonidal

RISK FACTORS
- Sedentary/prolonged sitting
- Excessive body hair
- Obesity/increased sacrococcygeal fold thickness
- Congenital natal dimple
- Trauma to coccyx

GENERAL PREVENTION
- Weight loss
- Trim hair in/around gluteal cleft weekly.
- Hygiene
- Ingrown hair prevention/follicle unblocking
DIAGNOSIS

HISTORY
Three distinct clinical presentations
- Asymptomatic: painless cyst or sinus at the top of the gluteal cleft
- Acute abscess: severe pain, swelling, discharge from the top of the gluteal cleft that may or may not have drained spontaneously
- Chronic abscess: persistent drainage from a sinus tract at the top of the gluteal cleft

PHYSICAL EXAM
- Common: inflamed cystic mass at the top of the gluteal cleft with limited surrounding erythema ± drainage or a sinus tract
- Less common: significant cellulitis of the surrounding tissues near the gluteal cleft

DIFFERENTIAL DIAGNOSIS
- Furunculosis
- Hidradenitis suppurativa
- Anal fistula
- Perirectal abscess
- Crohn disease

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Consider CBC and wound culture but generally not necessary for less severe infections.
- MRI might be considered to differentiate between perirectal abscess and pilonidal disease.

TREATMENT

GENERAL MEASURES
Shave area; remove hair from crypts weekly.

MEDICATION
- Antibiotics not indicated unless there is significant cellulitis (1)
- If antibiotics are needed, a culture to direct therapy might be useful.
- Cefazolin plus metronidazole or amoxicillin-clavulanate are often used empirically if cellulitis is suspected.

ISSUES FOR REFERRAL
- Patients who cannot comply with frequent dressing changes required after incision and drainage (I&D)
- Patients who have recurrence after I&D
- Patients who have complex disease with multiple sinus tracts

ADDITIONAL THERAPIES
- I&D with only enough packing to allow the cyst to drain; overpacking not indicated
- Antibiotics only if significant cellulitis; temporizing, not curative
- Negative pressure wound therapy
Laser epilation of hair in the gluteal fold (2)[B]
Phenol treatment can be used, especially for recurring disease.

Surgery/Others Procedures
Six levels of care based on severity or recurrence of disease; recent innovations in technique are aimed at expediting healing and minimizing recurrence.

- I&D, remove hair, curette granulation tissue (3)[A]
- Excision of midline “pits” allows drainage of lateral sinus tracts (pit picking).
- Pilonidal cystotomy: Insert probe into sinus tract, excise overlying skin, and close wound (4) [B].
- Marsupialization: Excise overlying skin and roof of cyst, and suture skin edges to cyst floor (3,5)[B].
- Excision: use of flap closure; no clear benefit for open healing over surgical closure
- Off-midline surgical excision (cleft lift or modified Karydakis procedure): A systematic review showed a clear benefit in favor of off-midline rather than midline wound closure. When closure of pilonidal sinuses is the desired surgical option, off-midline closure should be the standard management (3)[A].
- Endoscopic pilonidal sinus treatment (EPSiT): minimally invasive procedure (6)

Admission, Inpatient, and Nursing Considerations
- Severe cellulitis
- Large area excision

Ongoing Care

FOLLOW-UP RECOMMENDATIONS
- Frequent dressing changes required after I&D
- Follow up wound checks to assess for recurrence.

Patient Monitoring
Monitor for fever; more extensive cellulitis

Patient Education
- Wash area briskly with washcloth daily.
- Shave the area weekly.
- Remove any embedded hair from the crypt.
- Avoid prolonged sitting.

Prognosis
- Simple I&D has a 55% failure rate; median time to healing is 5 weeks.
- More extensive surgical excisions involve hospital stays and longer time to heal.

Complications
Malignant degeneration is a rare complication of untreated chronic pilonidal disease.

References

ADDITIONAL READING

CODES

ICD10
- L05.91 Pilonidal cyst without abscess
- L05.92 Pilonidal sinus without abscess
- L05.01 Pilonidal cyst with abscess

CLINICAL PEARLS
- Avoid prolonged sitting.
- Lose weight.
- Trim hair in gluteal cleft weekly.
- Refer recurring infections for more definitive surgical management.
PINWORMS
Jonathan MacClements, MD, FAAFP

BASICS

DESCRIPTION
- Intestinal infection with Enterobius vermicularis
  - Characterized by perineal and perianal itching
  - Usually worse at night
- System(s) affected: gastrointestinal; skin/exocrine
- Synonym(s): enterobiasis

EPIDEMIOLOGY
Predominant age: 5 to 14 years

Prevalence
- Most common helminthic infection in the United States
  - 20 to 42 million people harbor the parasite.
- ~30% of children are infected worldwide.

Pediatric Considerations
More common in children, who are more likely to become reinfected.

ETIOLOGY AND PATHOPHYSIOLOGY
- Small white worms (2 to 13 mm) inhabit the cecum, appendix, and adjacent portions of the ascending colon following ingestion.
- Female worms migrate to the perineal areas at night to deposit eggs; this causes local irritation and itching.
- Scratching leads to autoingestion of the eggs and continuation of pinworm’s life cycle within the host. Eggs incubate 1 to 2 months in the host’s small intestine. When mature, female pinworms migrate to the colon where they lay eggs around the anus at night, and the lifecycle continues.
- Infestation by the intestinal nematode E. vermicularis

RISK FACTORS
- Institutionalization (prevalence over 50%)
- Crowded living conditions
- Poor hygiene
- Warm climate
- Handling of infected children’s clothing or bedding

GENERAL PREVENTION
- Hand hygiene, especially after bowel movements
- Clip and maintain short fingernails.
- Wash anus and genitals at least once a day, preferably during shower.
- Avoid scratching anus and putting fingers near nose (pinworm eggs can also be inhaled) or mouth.
COMMONLY ASSOCIATED CONDITIONS
Pruritus ani

DIAGNOSIS

HISTORY
Many patients are asymptomatic. Common symptoms include the following:
- Perianal or perineal itching
- Vulvovaginitis
- Dysuria
- Abdominal pain (rare)
- Insomnia (typically due to pruritus)

PHYSICAL EXAM
Perineal and perianal exam; particularly in early morning to look for evidence of migrating worms

DIFFERENTIAL DIAGNOSIS
- Idiopathic pruritus ani
- Atopic dermatitis, contact dermatitis
- Psoriasis; lichen planus
- Human papillomavirus (HPV)
- Herpes simplex virus (HSV)
- Fungal infections; erythrasma
- Scabies
- Vaginitis; hemorrhoids
- Crohn disease; ulcerative colitis

DIAGNOSTIC TESTS & INTERPRETATION
- Adhesive tape test
  - Place cellophane tape on the perianal skin in the early morning before bathing and affix to a microscope slide to look for pinworm eggs.
  - 90% sensitivity if performed on three consecutive mornings
  - Alternatively, use anal swabs or a pinworm paddle coated with adhesive material.
  - Scrapings from under fingernails of affected individuals can reveal pinworm eggs.
- Digital rectal exam with saline slide preparation of stool on gloved finger
- Stool samples are not helpful.
- Routine stool examination for ova and parasites is positive in only 10–15% of infected patients.

Initial Tests (lab, imaging)
Serologic tests are currently not available for diagnosing pinworm infections.

Test Interpretation
Identification of ova on low-power microscopy or direct visualization of the female worm (10-mm long); ova are asymmetric, flat on one side, and measure 56 × 27 μm.
TREATMENT

MEDICATION

First Line

- Treatment options include:
  - Albendazole (Albenza): 400 mg PO as a single dose in adults and children >20 kg; may repeat in 2 weeks; 200 mg PO as a single dose repeated in 2 weeks in children ≤20 kg \(^2\) [A]
  - Mebendazole (Emverm, Vermox): chewable 100-mg tablet as a single dose in adults and children >2 years of age; may repeat in 2 to 3 weeks; use with caution in children <2 years of age \(^2\) [A].
  - Pyrantel pamoate (Pin-X, Reese Pinworm Medicine): oral liquid or tablet 11 mg/kg as a single dose in adults and children >2 years of age; maximum dose 1 g. Use with caution in children <2 years of age \(^2\) [A].

- Repeat treatment after 2 weeks is often recommended due to the high frequency of reinfection. Refractory cases may (rarely) require retreatment every 2 weeks for 4 to 6 cycles.
- All symptomatic family members should be treated.

Pregnancy Considerations

Avoid drug therapy in pregnancy as all 3 drugs are FDA Pregnancy Category C. Treat after delivery but may consider treating in 3rd trimester if infection is compromising the pregnancy. Breastfeeding is OK during mebendazole therapy \(^2\) [A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Unnecessary unless symptoms recur after initial therapy

PATIENT EDUCATION

- Take medicine with food.
- Practice good hygiene: hand washing and perianal hygiene; particularly after bowel movements
- Encourage frequent and careful hand washing.
- Clip fingernails.
- Wash clothing and bedding after diagnosis to prevent reinfection. Do not shake linen and clothing before laundering because this may spread the eggs.
- Do not share washcloths.
- Do not allow children to cobathe during treatment and for 2 weeks after treatment; showering is preferred.

PROGNOSIS

- Asymptomatic carriers are common.
- Drug therapy is 90% curative.
- Reinfection is common, especially among children.

COMPLICATIONS
Perianal scratching may lead to bacterial superinfection.

Females: vulvovaginitis, urethritis, endometritis, and salpingitis (3)[A]

UTIs

Rarely: ectopic disease with granulomas of the pelvis, genitourinary tract, and appendix; colonic intussusception (4)[A]

REFERENCES

ADDITIONAL READING

SEE ALSO

Pruritus Ani

CODES

ICD10

B80 Enterobiasis

CLINICAL PEARLS

- Nocturnal or early morning perianal itch with restless sleep or insomnia (particularly in children) is the hallmark of symptomatic pinworm infection.

- Treatment includes of mebendazole, albendazole, or pyrantel pamoate.

- Treat close contacts.
- Retreatment after 2 weeks is generally recommended.
PITUITARY ADENOMA
Anup K. Sabharwal, MD, MBA, FACE • Lewis S. Blevins Jr., MD

BASICS

DESCRIPTION
Typically benign, slow-growing tumors that arise from cells in the pituitary gland
- Pituitary adenomas have been identified as the third most frequent intracranial tumor; accounts for 10–25%
- Subtypes (hormonal): prolactinoma (PRL) 25–40%, nonfunctioning pituitary adenomas 30%, somatotroph adenoma (growth hormone [GH]) 15–20%, corticotroph adenoma (adrenocorticotropic hormone [ACTH]) 5–10%, thyrotroph adenoma (thyroid-stimulating hormone [TSH]) <1%, gonadotropinoma (luteinizing hormone/follicle-stimulating hormone [LH/FSH]), mixed (1)[A]
- Defined as microadenoma <10 mm and macroadenoma ≥10 mm
- May secrete hormones and/or cause mass effects

EPIDEMIOLOGY
- Predominant age: Age increases incidence.
- Predominant sex: female > male (3:2) for microadenomas (often delayed diagnosis in men)

Incidence
- Autopsy studies have found microadenomas in 3–27% and macroadenomas in <0.5% of people without any pituitary disorders.
- MRI scans illustrate abnormalities consistent with pituitary adenoma in 1/10 persons.
- Clinically apparent pituitary tumors are seen in 18/100,000 persons.

ETIOLOGY AND PATHOPHYSIOLOGY
- Monoclonal adenohypophysial cell growth
- Hormonal effects of functional microadenomas often prompt diagnosis before mass effect.
- PRL increased by functional prolactinomas or inhibited dopaminergic suppression by stalk effect

Genetics
- Carney complex
- Familial isolated pituitary adenomas: ~15% have mutations in the aryl hydrocarbon receptor–interacting protein gene (AIP); present at a younger age and are larger in size (2)
- McCune-Albright syndrome
- Multiple endocrine neoplasia type 1 (MEN1)-like phenotype (MEN4): germline mutation in the cyclin-dependent kinase inhibitor 1B (CDKN1B) (2)

RISK FACTORS
Multiple endocrine neoplasias

DIAGNOSIS
HISTORY

- Common
  - Hyperprolactinemia: infertility, amenorrhea, galactorrhea, gynecomastia, impotence
  - Headache (sellar expansion)
  - Visual disturbances: bitemporal hemianopsia
- Less common
  - Hypersomatotropinemia: acromegaly (coarse facial features, hand/foot swelling, carpal tunnel syndrome, hyperhidrosis, left ventricular hypertrophy)
  - Hyposomatotropinemia: failure to thrive (FTT) (children), asymptomatic (adults)
  - Intracranial pressure (ICP) elevation: headache, nausea, seizures
  - Hypercorticotropinemia: Cushing disease (supraclavicular/dorsocervical fat pad thickening, moon face, hirsutism, acne, plethora, abdominal striae, centripetal obesity with thin limbs, easy bruising and bleeding, hyperglycemia)
- Rare
  - Apoplexy: headache, sudden collapse
  - Secondary hyperthyroidism: palpitations, diaphoresis, heat intolerance, diarrhea
  - Secondary adrenal insufficiency: weakness, irritability, anorexia, nausea/vomiting

PHYSICAL EXAM

- Common
  - Visual disturbances: bitemporal hemianopsia
  - Hyperprolactinemia: hypogonadism, galactorrhea, gynecomastia
  - Hypersomatotropinemia: acromegaly (coarse features, hand/foot swelling, diaphoresis)
  - Hyposomatotropinemia: FTT (children)
- Less common
  - ICP elevation: papilledema, dementia
  - Cushing disease: centripetal obesity, supraclavicular fat pad thickening, moon face, hirsutism, acne
- Rare
  - Apoplexy: hypotension, hypoglycemia, tachycardia, oliguria
  - Secondary hyperthyroidism: tachycardia, tachypnea, diaphoresis, warm/moist skin, tremor
  - Adrenal crisis: orthostatic hypotension

HYPOTHALAMIC COMPRESSION: temperature dysregulation, obesity, increased urination

DIFFERENTIAL DIAGNOSIS

- Pituitary hyperplasia (e.g., pregnancy, primary hypothyroidism, menopause), Rathke cleft cyst, granulomatous disease (e.g., tuberculosis), lymphocytic hypophysitis, metastatic tumor, germinoma, craniopharyngioma

DIAGNOSTIC TESTS & INTERPRETATION

- Select based on dysfunction(s) suspected
- Somatotrophic (GH secreting: 40 to 130/million)
  - Acromegaly/hypersomatotropinemia: serum IGF-1 elevated; oral glucose tolerance test with GH given at 0, 30, and 60 minutes (normally suppresses GH to <1 g/L)
  - Hyposomatotropinemia: low GH-releasing hormone response

- Macimorelin is a noninvasive oral test to evaluate for adult GH deficiency (3)[A].
Corticotropic
- Cushing disease/hypercorticotropinemia
- 24-hour urinary-free cortisol >50 μg
- Overnight low-dose dexamethasone suppression test (DMST): normal free plasma cortisol (FPC) >1.8 μg/dL at 8 am (after 1 mg given at 11 pm on night prior)
- ACTH level assay (if DMST results abnormal): <20 pg/mL = adrenal tumor; ≥20 pg/mL = ectopic/pituitary source
- Hypocorticotropinemia/secondary glucocorticoid deficiency: high-dose corticotropin stimulation test: FPC <10 g/dL at baseline, with an increase of <25% 1 hour after 250 μg; metyrapone test: 11-deoxycortisol <150 ng/L after 2 g given (Prepare to give steroids because test may worsen insufficiency.)

Gonadotrophic/hypogonadotropinism: gonadotropin-releasing hormone stimulation of LH/FSH blunted in pituitary hypergonadism but increased in primary hypogonadism

Lactotrophic (PRL secreting): hyperprolactinemia: serum PRL >20 ng/mL

Thyrotrophic (TSH secreting): hyper-/hypothyroidism: TSH and free T_4 both increased for pituitary hyperthyroidism and both decreased for pituitary hypothyroidism.

Initial Tests (lab, imaging)
- A typical panel for asymptomatic tumors: PRL, GH, IGF-1, ACTH, 24-hour urinary-free cortisol or overnight DMST, β-HCG, FSH, LH, TSH, free T_4
- Maintain the same GH and IGF-1 through patient management (4)[C].
- Screening for AIP mutations may be offered to families of patients with pituitary adenoma, where available.
- MRI preferred (>90% sensitivity and specificity) after biochemically confirmed
- Octreotide scintigraphy is useful in identifying tumors with somatostatin receptors (4)[B].

Diagnostic Procedures/Other
Inferior petrosal sinus sampling: ACTH sampled from inferior petrosal sinuses to distinguish Cushing disease (pituitary source) from ectopic ACTH

Test Interpretation
- Cell types identified by immunohistochemistry
- Light microscope: eosinophilic (GH, PRL), basophilic (FSH/LH, TSH, ACTH), chromophobic

TREATMENT
Medical therapy is primary therapy for prolactinomas and adjunct for other tumors.

MEDICATION
First Line
- Hyperprolactinemia: Dopamine agonists increase dopaminergic suppression of PRL.
  - Cabergoline (Dostinex): D_2 receptor–specific
    - Initial dose: 0.25 mg PO once or twice weekly
    - Maintenance dose: Increase q4wk by 0.25 mg 2 times per week per PRL (max 2 mg/week).
    - Contraindications: hypersensitivity (ergots), uncontrolled hypertension (HTN), pregnancy
- Precautions: caution with liver impairment
- Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
- Adverse reactions: orthostatic hypotension, vertigo, dyspepsia, hot flashes
  - Bromocriptine (Parlodel): D2 receptor–specific
    - Initial dose: 1.25 to 2.50 mg PO daily (give with food)
    - Maintenance dose: Increase by 2.5 mg/day q2–7d (max 15 mg/day).
    - Contraindications: hypersensitivity (ergots), uncontrolled HTN, pregnancy; preferred over cabergoline if required
    - Precautions: caution with liver impairment
    - Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
    - Adverse reactions: orthostatic hypotension, seizures, hallucinations, stroke, myocardial infarction

- Somatotropinoma
  - Long-acting analogues of somatostatin (Sandostatin LAR and lanreotide Autogel)
    - Sandostatin LAR: 20 mg q28d (4)[A]; lanreotide Autogel 90 mg q28d; titrate per package insert.
    - Contraindication: hypersensitivity
    - Precautions: caution with biliary, thyroid, cardiac, liver, or kidney disease
    - Interactions: Pimozide increases risk of QT prolongation; variable effects with β-blockers, diuretics, oral glycemic agents
    - Adverse reactions: ascending cholangitis, arrhythmias, congestive heart failure, glycemic instability
    - More effective as adjuvant than as primary treatment for somatotropinomas
    - Consider use of somatostatin analogue or pegvisomant in patients with severe residual disease (4)[A].
    - Consider use of cabergoline in patients with mild residual disease (5)[B].
  - Pegvisomant (Somavert): GH receptor antagonist
    - Initial dose: 40 mg SC × 1, then 10 mg daily and titrate by 5 mg every 4 to 6 weeks based on IGF-1 levels (max 30 mg/day maintenance dose)
    - Contraindication: hypersensitivity
    - Precautions: caution if GH-secreting tumors, diabetes mellitus, impaired liver function
    - Interactions: NSAIDs, opiates, insulins, oral glycemic agents
    - Adverse reactions: hepatitis, tumor growth, GH secretion

- Corticotropinemia: peripheral inhibitors
  - Mitotane (Lysodren)
    - Initial dose: 2 to 6 g/day divided PO TID (max 19 g/day)
    - Maintenance dose: 2 to 16 g TID
    - Contraindication: hypersensitivity
    - Precautions: caution with liver dysfunction and brain damage
    - Interactions: contraindicated with rotavirus vaccine; caution with other vaccines
    - Adverse reactions: HTN, orthostatic hypotension, hemorrhagic cystitis, rash
  - Ketoconazole
    - Dosing: 200 mg PO TID (max 1,200 mg/day)
    - Contraindications: hypersensitivity, achlorhydria, fungal meningitis, impaired liver function
    - Precautions: caution with liver dysfunction
Interactions: contraindicated with dronedarone, methadone, statins, pimozide, sirolimus; caution with other antifungals
Adverse reactions: adrenal insufficiency, thrombocytopenia, hepatic failure, hepatotoxicity, anaphylaxis, leukopenia, hemolytic anemia

Pasireotide (Signifor)
- Dosing: initially, 0.6 to 0.9 mg twice daily and then 0.3 to 0.9 mg twice daily
- Contraindication: none
- Precautions: hypocortisolism, hyperglycemia, bradycardia or QT prolongation, liver test elevations, cholelithiasis, and other pituitary hormone deficiencies

Mifepristone (Korlym)
- Dosing: Administer PO once daily with a meal. The recommended starting dose is 300 mg once daily; not to exceed 600 mg daily in renal impairment
- Contraindication: pregnancy, use of simvastatin or lovastatin and CYP3A substrates with narrow therapeutic range, concurrent long-term corticosteroid use, women with history of unexplained vaginal bleeding, women with endometrial hyperplasia with atypia or endometrial carcinoma
- Precautions: adrenal insufficiency, hypokalemia, vaginal bleeding and endometrial changes, QT interval prolongation, use of strong CYP3A inhibitors
- Interactions: potential interactions with drugs metabolized by CYP3A, CYP2C8/9, CYP2B6, and hormonal contraceptives. Nursing mothers should discontinue drug or discontinue nursing.
- Adverse reactions: most common adverse reactions in Cushing syndrome (≥20%): nausea, fatigue, headache, decreased blood potassium, arthralgia, vomiting, peripheral edema, HTN, dizziness, decreased appetite, endometrial hypertrophy

Gonadotropinemia
- Bromocriptine: See earlier discussion.

Thyrotropinemia
- Somatostatin analogues: See earlier discussion.

Second Line
- Corticotropinemia: peripheral inhibitors
  - Metyrapone
    - Dose: 250 mg PO QID
    - Contraindication: porphyria
    - Precautions: caution in liver/thyroid disease
    - Interactions: Dilantin increases metabolism.
    - Adverse reactions: nausea, hypotension

Gonadotropinemia
- Octreotide: See earlier discussion.

ISSUES FOR REFERRAL
- Neurosurgery consultation for symptomatic tumors (except for prolactinoma)
- Ophthalmologist evaluation prior to surgery

ADDITIONAL THERAPIES
- Fractionated radiotherapy: often effective as adjunctive when surgery is inadequate
- Stereotactactic radiosurgery: alternative to surgery in high-risk patients or as adjunct
SURGERY/OTHER PROCEDURES
- Most are now done endoscopically via translabial/transsphenoidal approach (6)[A].
- Indications: symptoms or treatment resistant
- Follow-up: serial neurologic/hormonal evaluations to evaluate complications (e.g., diabetes insipidus, CNS damage) and need for more treatment
- Remission rates: 72–87% for microadenoma but only 50–56% for macroadenomas

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient management unless apoplexy or adrenal crisis
- Treat pituitary apoplexy immediately to prevent death (see “Complications”) (6)[A].
- Consider stress-dose steroids in frail or hemodynamically unstable patients.
- Maintain BP with fluids and/or pressor agents.
- Check serum sodium, serum osmolality, and urine specific gravity if polyuric or electrolytes are imbalanced.
- Contact neurosurgery.
- Diabetes insipidus: hyperosmolar IV fluids
- Adrenal crisis: normal saline
- Pituitary apoplexy: Monitor inputs/outputs (I/Os), central venous pressure, and ICP and do frequent neurologic checks.
- Adrenal crisis: Monitor BP and I/Os.
- Keep as inpatient postoperatively until diabetes insipidus and/or adrenal insufficiency is managed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow-up MRIs at 6 and 12 months after discharge
- Involved hormone(s) are followed postoperatively, especially after radiation because hypopituitarism may develop 10 to 15 years after treatment.

PROGNOSIS
Depends on type, size, symptoms, therapy

COMPLICATIONS
- Postoperative diabetes insipidus and/or hypogonadism (usually transient/common)
- Pituitary apoplexy (acute/uncommon): acute hemorrhagic pituitary infarction; adrenal crisis with severe headache; surgical decompression required to prevent shock, coma, and death
- Nelson syndrome (subacute/uncommon): rapid adenoma growth postadrenalectomy
- Pituitary hormone insufficiency (chronic/uncommon): often years after treatment
- Optic nerve neuropathy and brain necrosis after >60 Gy radiotherapy (chronic/rare)

Cushing Disease and Cushing Syndrome; Galactorrhea

CODES
ICD10
D35.2 Benign neoplasm of pituitary gland

CLINICAL PEARLS
- An incidentaloma is an asymptomatic microadenoma found on imaging. General labs include PRL, GH, IGF-1, ACTH, 24-hour urinary-free cortisol/overnight DMST, β-subunit FSH, LH, TSH, and free T4. Obtain follow-up MRIs at 6 and 12 months if normal, but consult endocrinology if not.
- Initial treatment selected for symptomatic pituitary adenoma includes a dopamine agonist for prolactinomas and surgical resection for all others.
- Pituitary apoplexy is a rapid hemorrhagic pituitary infarction due to compression of the blood supply. It is fatal within hours unless surgically decompressed.
PLANTAR FASCIITIS
Brooke E. Organ, DO  Krystyna Guinevere Golden, MD  Roselyn Jan W. Clemente-Fuentes, MD, FAAFP

BASICS

DESCRIPTION
- Degenerative change of plantar fascia at origin on medial tuberosity of calcaneus
- Pain on plantar surface, usually at calcaneal insertion of plantar fascia upon weight-bearing, especially in morning or on initiation of walking after prolonged rest
- Also referred to as: plantar fasciosis, plantar heel pain syndrome, heel spur syndrome, plantar fasciopathy, painful heel syndrome

EPIDEMIOLOGY

Prevalence
- Most common cause of plantar heel pain
- Lifetime: 10–15% of population
- Peak incidence between ages 40 and 60 years, earlier peak in runners

ETIOLOGY AND PATHOPHYSIOLOGY

- Repetitive microtrauma and collagen degeneration of plantar fascia
- Chronic degenerative change (-osis/-opathy rather than -itis) of plantar fascia generally at insertion on medial tuberosity of calcaneus

RISK FACTORS

Intrinsic
- Age (>40 to 60 years)
- Female, pregnancy
- Obesity (BMI >30)
- Pes planus (flat feet), pes cavus (high arch), overpronation, leg length discrepancy
- Hamstring, calf, and Achilles tightness
- Calf and intrinsic foot muscle weakness
- Decreased ankle range of motion with dorsiflexion (equinus or tight heel cord; <15 degrees of dorsiflexion)
- Systemic connective tissue disorders

Extrinsic
- Dancers, runners, court sport athletes
- Occupations with prolonged standing, especially on hard surfaces (nurses, letter carriers, warehouse/factory workers)
- Overuse and rapid increase in activities involving repetitive loading

GENERAL PREVENTION

- Maintain normal body weight.
- Avoid prolonged standing on bare feet, in sandals, or in slippers.
- Avoid training errors (increasing intensity, distance, duration, and frequency of high-impact
activities too rapidly); avoid overtraining.
• Proper footwear (appropriate cushion/arch support)
• Runners should replace footwear every 250 to 500 miles.

COMMONLY ASSOCIATED CONDITIONS
• Usually isolated
• Heel spurs common but not a marker of severity
• Posterior tibial neuropathy

DIAGNOSIS

HISTORY
• Pain on plantar surface of foot, usually at fascial insertion at calcaneus (medial calcaneal tubercle), but can have pain anywhere along length of plantar fascia
• Pain is typically worse with first few steps in the morning or after prolonged rest or standing (poststatic dyskinesia).
• Pain typically improves after first few steps only to recur toward the end of the day or after prolonged ambulation.
• Pain commonly unilateral but can be bilateral in 1/3 of cases
• Pain can be dull and constant in chronic cases.
• Limp with excessive toe walking
• Numbness and burning of medial hindfoot when associated with posterior tibial nerve compression

PHYSICAL EXAM
• Point tenderness on medial tuberosity of calcaneus at insertion of plantar fascia
• Pain along plantar fascia with dorsiflexion of foot
• Windlass test: Extend MTP while allowing passive flexion of IP joint of hallux—pain indicates a positive test; high specificity, low sensitivity; sensitivity improves (13.5 to 31.8%) if performed while standing.
• Dorsiflexion-eversion test: pain with dorsiflexion plus eversion of the subtalar joint
• Decreased passive range of motion with dorsiflexion
• Evaluate for pes planus, pes cavus, and overpronation.
• Loss of heel fat pad suggests heel fat pad syndrome.
• Point tenderness on posterosuperior aspect of heel suggests Achilles tendinopathy.

DIFFERENTIAL DIAGNOSIS
• Calcaneal stress fracture
• Heel fat pad syndrome (painful or atrophic heel pad)
• Longitudinal arch strain
• Nerve entrapment (posterior tibial nerve—tarsal tunnel syndrome, medial calcaneal branch of posterior tibial nerve, abductor digiti quinti)
• Achilles tendinopathy
• Calcaneal contusion
• Plantar calcaneal bursitis
• Tendinitis of posterior tibialis
• Plantar fascia tear
S1 radiculopathy
Adolescents: calcaneal apophysitis (Sever disease)

DIAGNOSTIC TESTS & INTERPRETATION

- Usually not necessary; typically a clinical diagnosis
- Consider further imaging only to rule out other causes, uncertain diagnosis, or persistent heel pain after 4 to 6 months of conservative therapy.
- Radiographs: two views of foot to evaluate for fracture, tumor, cyst, periostitis, bony erosions; weight-bearing films preferred; calcaneal spurs common but not diagnostic
- Ultrasound: hypoechoic at insertion, thickened plantar fascia (≥4 mm); diagnostic and even therapeutic when used as an adjunct to treatment; can improve delivery accuracy of injections and extracorporeal shock wave therapy (ESWT); can objectively evaluate change in plantar fascia thickness to monitor effects of an intervention
- MRI can evaluate for other soft tissue etiologies.
- CT or technetium-99m bone scan can rule out calcaneal stress fracture and evaluate for infection.
- Nerve conduction studies can rule out nerve entrapment.
- Inflammatory markers: can consider if bilateral heel pain or young patients

TREATMENT

Non-operative management is mainstay of treatment.

GENERAL MEASURES

- Supportive footwear with stable midfoot; avoid sandals or walking barefoot.
- Relative rest/activity modification with avoidance of high-impact causative activities
- Stretching: plantar fascia stretches more effective than Achilles tendon/gastrocnemius-soleus stretches, and non–weight-bearing stretches may be preferable
- Plantar fascia mobilization: Foot to inversion; compress tender point while moving foot to eversion; repeat along plantar fascia
- Strengthen calf and interosseous muscles, using the towel drag/pickup exercise.
- Ice (frozen water bottle roll)
- Massage (golf or tennis ball roll) of Tibialis Anterior
- Weight reduction if BMI >25
- Orthotics
  - Custom orthotics show no benefit over prefabricated orthotics and are more costly.
  - Arch support straps or heel cups are inexpensive and may be used in place of or in addition to orthotics.
  - Improved effectiveness of night splints when used in association with orthotics
- Night splints: maintains dorsiflexion overnight; effective with calf and Achilles tightness
- Surgical treatment of “heel spurs” is not indicated.

MEDICATION

First Line
- NSAIDs scheduled for 2 to 3 weeks: naproxen 500 mg PO BID or ibuprofen 600 to 800 mg PO TID PRN for pain
- Acetaminophen 1,000 mg PO TID PRN for pain
ISSUES FOR REFERRAL

- Physical therapy for patient instruction on proper stretching and strengthening techniques, manipulative treatments (joint and soft tissue mobilization), and massage. For chronic cases, consider analysis of gait and biomechanical factors.
- Podiatry: Consider if conservative measures fail after 3 to 6 months.
- Surgery: Consider if conservative measures fail after 6 to 12 months.

ADDITIONAL THERAPIES

- Corticosteroid injections (1)[B]
  - Short-term pain relief
  - Medial heel approach or points of maximal tenderness along plantar fascia
  - Recommend ultrasound guidance when possible.
  - Risk for plantar fascia rupture and calcaneal fat pad atrophy with resultant permanent heel pain
- Low-dye and calcaneal taping
- Short walking cast
- Promising therapies with inconsistent evidence
  - Extracorporeal Shock Wave Therapy (ESWT) (2)[B]
  - Radiofrequency nerve ablation (3)[B]
  - Plantar iontophoresis
  - Intralesional autologous blood injection
  - Low-level laser therapy
  - Acupuncture
  - Myofascial trigger point dry needling (4)[B]
  - Platelet-rich plasma (PRP) injections (5)[B]
  - Botulinum toxin (BT) A injection (6)[B]
  - Ozone injections
  - Polydeoxyribonucleotide (PDRN) injections

SURGERY/OTHER PROCEDURES

- Necessary in <10% of patients; more likely beneficial in severely obese
- Recommended if conservative treatment fails after 6 to 12 months and pain is unrelenting
- Open/endoscopic plantar fasciotomy (less risk and complications with endoscopic technique but requires specialized equipment and skills; not widely used)
- Cryosurgery
- Calcaneal spur resection

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture may reduce pain in short term, but further studies needed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Ensure patient adherence to proper stretching technique.
Following 3 to 6 months of unsuccessful conservative treatment, consider additional therapies or referrals.

PATIENT EDUCATION
- Weight reduction if BMI >25
- Proper footwear (adequate cushion and arch support)
- Stretch plantar fascia: Pull toes into dorsiflexion prior to walking after prolonged sitting or sleep.
- Ice the foot using a frozen water bottle: Roll foot over bottle for 10 minutes in the morning and after work.
- Massage plantar fascia: Roll foot over a golf ball.
- Strengthen foot muscles: Grab cloth or carpet by plantar flexing the toes.
- Decrease repetitive stress.

PROGNOSIS
- Generally good
- Self-limited (resolves within 12 months) in up to 80–90% of patients

COMPLICATIONS
- Rupture of plantar fascia (more common with repeated corticosteroid injections)
- Chronic pain
- Gait abnormality

- Bahrami MH, Raeissadat SA, Barchinejad M, et al. Local ozone (O₂-O₃) versus corticosteroid

SEE ALSO
Algorithm: Heel Pain

CODES
ICD10
M72.2 Plantar fascial fibromatosis

CLINICAL PEARLS

- Plantar fasciitis occurs due to degeneration of plantar fascia at origin (medial calcaneal tuberosity) with characteristic pattern of pain.
- Plantar medial heel pain with weight-bearing (most noticeable with initial steps in the morning or after period of inactivity) is hallmark presentation.
- Generally, self-limited and conservative treatment is preferred. 85–90% of patients can be treated with conservative therapies.
- Supportive footwear helps avoid excess pronation and provides adequate cushion and arch support. Modify activity, stretch plantar fascia, strengthen intrinsic foot muscles, ice (water bottle roll), and massage (golf ball roll).
- Weight loss helps control symptoms, particularly for BMI ≥25.
PLEURAL EFFUSION
Felix B. Chang Cruz, MD, FAAMA, ABIHM

BASICS
Abnormal accumulation of fluid in the pleural space

DESCRIPTION
Types: transudate (low protein/low specific gravity) and exudate (high protein and cellular debris)
- Transudate: Congestive heart failure (CHF): 40%
- Exudates: pneumonia 25%, malignancy 15%, and pulmonary embolism (PE) 10%
  - Malignant: lung cancer and metastases of breast, ovary, and lymphoma

EPIDEMIOLOGY
Incidence
Estimated 1.5 million cases per year in the United States; CHF: 500,000; pneumonia: 300,000; malignancy: 150,000; PE: 150,000; cirrhosis: 150,000; tuberculosis (TB): 2,500; pancreatitis: 20,000; collagen vascular disease: 6,000

Prevalence
- Estimated 320 cases per 100,000 people in industrialized countries; in hospitalized patients with AIDS, prevalence is 7–27%.
- No gender predilection: ~2/3 of malignant pleural effusions occur in women.

ETIOLOGY AND PATHOPHYSIOLOGY
- Pleural fluid formation exceeds pleural fluid absorption.
- Transudates result from imbalances in hydrostatic and oncotic forces.
  - Increase in hydrostatic and/or low oncotic pressures; increase in pleural capillary permeability; lymphatic obstruction or impaired drainage; movement of fluid from the peritoneal or retroperitoneal space
- Transudates
  - CHF: 40% of transudative effusions; 80% bilateral; constrictive pericarditis, atelectasis; superior vena cava syndrome
  - Cirrhosis (hepatic hydrothorax); nephrotic syndrome, hypoalbuminemia; myxedema
  - Urinothorax, central line misplacement; peritoneal dialysis
  - Dressler syndrome (postmyocardial infarction syndrome)
  - Yellow nail syndrome: yellow nails, lymphedema and pleural effusion
- Exudates
  - Lung parenchyma infection, bacterial (parapneumonic, tuberculous pleurisy), fungal, viral, parasitic (amebiasis, Echinococcus)
  - Cancer: lung cancer, metastases (breast, lymphoma, ovaries), mesothelioma
  - PE: 25% of PEs are transudate.
  - Collagen vascular disease: rheumatoid arthritis, systemic lupus erythematosus (SLE), Wegener granulomatosis, sarcoidosis, Churg-Strauss
  - GI: pancreatitis, esophageal rupture, abdominal abscess, after liver transplant; chylothorax:
thoracic duct tear, malignancy
- Hemothorax: trauma, PE, malignancy, coagulopathy, aortic aneurysm
- Others: after coronary artery bypass graft; uremia, asbestos exposure, radiation; drug induced:
  - Drugs: nitrofurantoin, bromocriptine, amiodarone, procarbazine, hydralazine, procainamide, quinidine, methotrexate, methysergide, interleukin-2, mitomycin, practolol, minoxidil, bleomycin, cyclophosphamide, dantrolene, valproic acid, sulfasalazine, minocycline, acebutolol, phenytoin, practolol, minoxidil, methysergide, L-tryptophan, dasatinib.
- Meigs syndrome; yellow nail syndrome; ovarian stimulation syndrome; lymphangiomatosis; acute respiratory distress syndrome (ARDS)
- Chylothorax: thoracic duct tear, malignancy, associated with lymphoma

RISK FACTORS
- Occupational exposures/drugs
- PE, TB, bacterial pneumonias
- Opportunistic infections (in HIV patients when CD4 count is <150 cells/μL)

COMMONLY ASSOCIATED CONDITIONS
Hypoproteinemia, heart failure, cirrhosis

DIAGNOSIS
Presumptive diagnosis in 50% of cases. Small pleural effusions; radiographic area <2 intercostal spaces (<300 mL) are asymptomatic.

HISTORY
Dyspnea, fever, malaise, and weight loss; chest pain, cough, hemoptysis, and dull pain

PHYSICAL EXAM
- Pleural effusion >300 mL: tachypnea, asymmetric expansion of the thoracic cage; decrease/absent tactile fremitus; dullness to percussion; decreased/inaudible breath sounds, egophony, pleural friction rub
- Ascites suggest the following: hepatic hydrothorax, ovarian cancer, and Meigs syndrome.
- If associated with unilateral swelling in lower extremity, consider DVT with PE.

DIFFERENTIAL DIAGNOSIS
Empyema, malignancy, inflammatory, fungal, TB

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Pleural fluid: appearance, pH, WBC differential, total protein, lactate dehydrogenase (LDH), glucose, Gram stain and culture, and acid-fast bacilli staining. Consider polymerase chain reaction (PCR) for Mycobacterium tuberculosis and Streptococcus pneumoniae.
- If comorbidities implying risk, consider amylase, triglycerides, cholesterol, LE cells, cytology, antinuclear antibodies (ANAs), adenosine deaminase, tumor markers, rheumatoid factor, cytology, creatinine.
- Light criteria, transudate versus exudate (98% sensitivity; 80% specificity); fluid is considered
an exudate if any of the following:
- Ratio of pleural fluid-to-serum protein levels >0.5; ratio of pleural fluid-to-serum LDH levels >0.6; pleural fluid LDH level >2/3 the upper limit for serum LDH level (1)[A]

- Serum-effusion albumin gradient ≤1.2 (sensitivity 87%; specificity 92%); cholesterol effusion >45 mg/dL and LDH effusion >200 mg/dL (sensitivity 90%; specificity 98%)
- Empyema: pus, putrid odor; culture. A putrid odor suggests an anaerobic empyema: LDH levels >1,000 IU/L (normal serum = 200 IU/L); glucose, <60 mg/dL; low pH (2)[A]
- Malignancy: cytology, red, bloody; glucose, normal to low, depending on the tumor burden; RBCs, >100,000/mm³
- Lupus pleuritis: LE cells present; pleural fluid-to-serum ANAs ratio >1; glucose <60 mg/dL; pleural fluid-to-serum glucose ratio <0.5
- Fungal: positive KOH, culture; peritoneal dialysis: protein, <1 g/dL; glucose, 300 to 400 mg/dL
- Urinothorax: creatinine: pleural/blood >0.5; high LDH pleural fluid, with low protein levels
- Hemothorax: hematocrit: pleural/blood >0.5; benign asbestos effusion: unilateral, exudative; have elevated eosinophil count
- TB pleuritis: lymphocytes >80% predominance effusion; elevated levels of adenosine deaminase >50 U/L and interferon-γ >140 pg/mL; positive acid-fast bacillus (AFB) stain, culture; total protein >4 g/dL, nuclear acid amplification (NAA), LDH levels elevated in about 75% of patients (often >500 units/L) (3)[C]
- Chylothorax: milky; triglycerides >110 mg/dL; lipoprotein electrophoresis (chyomicrons)
- Amebic liver abscess: anchovy paste effusion; Waldenström macroglobulinemia and multiple myeloma: protein >7 g/dL
- Esophageal rupture: high salivary amylase; pleural fluid acidosis, pH <6; amylase rich: acute pancreatitis, chronic pancreatic pleural effusion, malignancy, esophageal rupture; rheumatoid pleurisy: glucose <60 mg/dL; pleural fluid-serum glucose <0.5
- Lymphocytosis: tuberculous pleurisy, lymphoma, sarcoidosis, chronic rheumatoid pleurisy, yellow nail syndrome, or chylothorax (80–95% of the nucleated cells); carcinomatosis in half of cases (50–70% are lymphocytes)
- Pleural fluid eosinophilia (>10% of total nucleated cells): pneumothorax, hemothorax, malignancy, drugs, pulmonary infarction, fungal (coccidioidomycosis, cryptococcosis, histoplasmosis), benign asbestos pleural effusion
- Low glucose (<60 mg/dL): TB, malignancy, rheumatoid pleurisy, parapneumonic, empyema, hemothorax, paragonimiasis, Churg-Strauss syndrome
- RBC count >100,000/mm³: trauma, malignancy, PE, injury after cardiac surgery, asbestos pleurisy, pancreatitis, TB
- Pleural fluid LDH >1,000 IU/L: suggests empyema, malignant effusion, rheumatoid effusion, or pleural paragonimiasis
- pH >7.3: rheumatoid pleurisy, empyema, malignant effusion, TB, esophageal rupture, or lupus nephritis
- Mesothelial cells in exudates: TB is unlikely if there are >5% of mesothelial cells.
- S. pneumoniae accounts for 50% of cases of parapneumonic effusions in AIDS patients, followed by Staphylococcus aureus, Haemophilus influenzae, Mycoplasma pneumoniae, Legionella, Nocardia, and Bordetella bronchiseptica; exudate with low count of nucleated cells
- Pneumocystis jiroveci is an uncommon cause in HIV. Usually it is a small effusion, unilateral
or bilateral, and serous to bloody in appearance. Demonstration of the trophozoite or cyst is mandatory.

- Cancer-related HIV pleural effusion: Kaposi sarcoma, Castleman disease, and primary effusion lymphoma. Kaposi sarcoma: mononuclear predominance, exudate, pH >7.4; LDH, 111 to 330 IU/L; glucose >60 mg/dL
- Chest x-ray (CXR): posteroanterior–anteroposterior views
  - Upright X-rays show a concave meniscus in the costophrenic angle that suggests >250 mL of pleural fluid; homogeneous opacity, with visibility of pulmonary vessels through diffuse haziness and absence of air bronchogram; 75 mL of fluid will obliterate the posterior costophrenic sulcus.
  - Lateral X-rays show blunting of the posterior costophrenic angle and the posterior gutter; decubitus X-rays to exclude a loculated effusion and underlying pulmonary lesion or pulmonary thickening
  - Supine X-rays show costophrenic blunting, haziness, obliteration of the diaphragmatic silhouette, decreased visibility of the lower lobe vasculature, and widened minor fissure.
- Ultrasonography (US): detects as 5 to 50 mL of pleural fluid; identifies loculated effusions; site for thoracentesis, pleural biopsy, or pleural drainage
- Chest CT scan with contrast for patients with undiagnosed pleural effusion; CT pulmonary angiography if PE is suspected

**Follow-Up Tests & Special Considerations**

75% of patients with exudative effusions have a non-CHF cause.

- NT-proBNP: biomarker of CHF-associated effusion; >1,500 pg/mL; sensitivity and specificity 94% (1)[A]
- In patients with a lymphocytic effusion, further investigation should be considered for TB, sarcoidosis, lymphoma, chylothorax, and pseudochylothorax.

**Diagnostic Procedures/Other**

Diagnostic thoracentesis indicated for the following:

- Clinically significant pleural effusion (>10-mm thick on US or lateral decubitus x-ray with no known cause)
- CHF: asymmetric effusion, fever, chest pain, or failure to resolve after diuretics
- Parapneumonic effusions

**TREATMENT**

Oxygen support to >92%

**GENERAL MEASURES**

- Therapeutic thoracentesis, if symptomatic
- Chest tube thoracostomy drainage: >1/2 hemithorax; complicated parapneumonic effusion (positive Gram stain or culture, pH <7.2, or glucose <60 mg/dL); empyema; hemothorax. Recommended limit is 1,000 to 1,500 mL in a single thoracentesis procedure.

**MEDICATION**

**First Line**

CHF: diuretics (75% clearing in 48 hours); parapneumonic effusion: antibiotics; rheumatologic
conditions/inflammation: steroids and NSAIDs

Second Line
Symptomatic nonmalignant effusions that are refractory to treatment may be managed with repeated therapeutic thoracentesis or pleurodesis.

ISSUES FOR REFERRAL
- Uncertain etiology; malignant effusion; high-risk diagnostic thoracentesis; decortication
- Video-assisted thoracoscopy for sclerosis; peritoneal shunts for symptomatic recurrence

ADDITIONAL THERAPIES
- Pleurodesis for symptomatic patients whose pleural effusion reaccumulates too quickly for repeat therapeutic thoracentesis
- Talc poudrage to be a highly effective method, 95% credible interval (Cr-1) 1 to 5
- Tunneled pleural catheter is the preferred treatment for patients with malignant pleural effusion and limited survival.
- Sclerosing agents for malignant effusions: doxycycline, bleomycin, talc, and minocycline; talc is more efficacious. The relative risk of nonrecurrent effusion was 1.34 (95% CI 1.16–1.55) in favor of talc compared with bleomycin, tetracycline, or mustine.

SURGERY/OTHER PROCEDURES
- Percutaneous pleural biopsy if a cause is not clear after thoracentesis
  - Close pleural biopsy: Pleura is diffusely involved (TB pleuritis, noncaseating granuloma in rheumatoid pleuritis).
  - CT-guided needle biopsy: pleural mass; video-assisted thoracoscopic pleural biopsy:
    - Negative percutaneous biopsy, patchy disease, or CT scan does not show obvious mass.
- Parapneumonic effusion should be sampled if free-flowing, but layer is >10 mm on a lateral decubitus film; loculated, thickened pleura on a contrast-enhanced CT scan, clearly delineated by US open pleural biopsy by thoracotomy
- Contraindications for thoracentesis: anticoagulation, bleeding diathesis, thrombocytopenia <20,000/mm³, mechanical ventilation
- Bronchoscopy: when malignancy is suspected (pulmonary infiltrate or mass on CXR or CT scan, hemoptysis, massive pleural effusion, or shift of the mediastinum toward the side of effusion)
- Thoracoscopy
  - No statistically significant difference in mortality between primary surgical and nonsurgical management of pleural empyema for all age groups (2)[A]
- Video-assisted thoracoscopic surgery may reduce length of hospital stay compared to thoracotomy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Treat any underlying medical disorder.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Check for the amount and quality of fluid drained, air leak (bubbling), and oscillation.
- Repeat a CXR when drainage decreases to <100 mL/day to evaluate complete clearing.
- For a large effusion, reevaluate catheter position; if positioned appropriately, consider fibrinolytics.

**DIET**
Cardiac diet in patients with heart failure; correct hypoproteinemia.

**PROGNOSIS**
- Malignant effusion: poor
- Low-pH malignant effusions have shorter survival and poorer response to chemical pleurodesis than those with pH >7.3.
- Low pleural fluid pH (≤7.15): high likelihood of pleural space drainage
- Malignant pleural effusion has a poor prognosis with 84% reported 1-year mortality among patient with bilateral pleural effusion.
- Pleural fluid pH ≤7.28 associated with reduced survival (odds ratio 4.42, 95% CI 2.39–8.46 for <1-month survival) (4)[A]
- Uncomplicated parapneumonic effusions and effusions from PE, tuberculous pleurisy, and postcardiac injury syndrome may persist for several weeks.
- Benign asbestos pleural effusion, rheumatoid pleurisy, and radiation pleuritis often persist for months to years.
- Malignant pleural effusions, on the other hand, seldom resolve spontaneously (5)[C].

**COMPLICATIONS**
- Pleural effusion: constrictive fibrosis, pleurocutaneous fistula
- Thoracentesis: pneumothorax (5–10%); hemothorax (~1%); empyema; spleen/liver laceration; reexpansion pulmonary edema (if >1.5 L is removed)

**REFERENCES**

**ADDITIONAL READING**
- Light RW, Macgregor MI, Luchsinger PC, et al. Pleural effusions: the diagnostic separation of

**CODES**

**ICD10**
- J90 Pleural effusion, not elsewhere classified
- J91.0 Malignant pleural effusion
- J94.0 Chylous effusion

**CLINICAL PEARLS**

- Bilateral pleural effusion suggests heart failure, malignancy in absence of cardiomegaly, and TB or parasitic infection in children.
- Measurement of adenosine deaminase may be helpful when an effusion is lymphocytic and the initial smear and culture for tuberculosis are negative.
- Pleural cytology has a sensitivity of 60 percent for pleural malignancy.
- CT scan of the thorax with contrast should be performed in virtually all patients with an undiagnosed pleural effusion.
- CT-guided needle biopsy is useful when a pleural-based soft tissue abnormality is identified by CT scan.
- Clues to the diagnosis of tuberculous pleurisy include risk factor for TB exposure and a lymphocytic effusion, especially when pleural adenosine deaminase and interferon-γ are elevated.
PNEUMONIA, BACTERIAL
Jocelyn C. Young, DO, MS ● Mohammad Humza Qureshi, MD

BASICS
Bacterial pneumonia is an infection of the pulmonary parenchyma by a bacterial organism.

DESCRIPTION
Bacterial pneumonia can be classified as the following:

- Community-acquired pneumonia (CAP): acute infection of the pulmonary parenchyma acquired outside of a health care setting or long-term care facility
- Nosocomial pneumonia: acute infection of the pulmonary parenchyma acquired in health care settings
  - Health care associated pneumonia (HCAP): occurs in a nonhospitalized patient with extensive health care contact, such as:
    - Residing in a long-term care facility
    - Hospitalization in an acute care hospital for ≥2 days within the past 90 days
    - Hemodialysis clinic within the past 30 days
  - Hospital-acquired pneumonia (HAP): occurs ≥48 hours after admission and did not appear to be incubating at time of admission
  - Ventilator-associated pneumonia (VAP): pneumonia that develops >48 hours after endotracheal intubation

EPIDEMIOLOGY
- In the United States as of 2017, community acquired pneumonia is the ninth most common cause of death (even higher in those older than 65 years) and most common cause of death related to infection
- Pneumonia causes 3.2 million estimated deaths globally
- HAP is the leading cause of death among nosocomial infections and is one of the leading causes of death in the ICU.
- Rates of infection are 3 times higher in African Americans than in whites and are 5 to 10 times higher in Native American adults and 10 times higher in Native American children.
- Mortality rate in children is approximately 1.6 million a year. Hospitalization rate for children with CAP is still highest among the very young ages (<18 months). Respiratory viruses are the most commonly detected causes of pneumonia in children (1).

Incidence
- CAP: 5 to 6 cases per 1,000 persons with increased incidence occurring in the winter months
- HAP: 5 to 20 cases per 1,000 admissions; incidence increases 6- to 20-fold in ventilated patients

ETIOLOGY AND PATHOPHYSIOLOGY
- Pathogenicity of the implicated organisms inform the presentation and antibiotic choice
- Adults, CAP
  - Typical (85%): Streptococcus pneumoniae, Haemophilus influenzae, Staphylococcus aureus, group A Streptococcus, Moraxella catarrhalis
– Atypical (15%): Legionella sp., Mycoplasma pneumoniae, Chlamyphila pneumoniae

• Adults, HCAP/HAP/VAP
  – Aerobic gram-negative bacilli: Pseudomonas aeruginosa, Escherichia coli, Klebsiella pneumoniae, and Acinetobacter sp.
  – Gram-positive cocci: Streptococcus sp. and S. aureus (including MRSA)

• Pediatric
  – Birth to 3 weeks: E. coli, group B Streptococci, Listeria monocytogenes
  – Less than 3 months: Chlamydia trachomatis, S. pneumoniae, H. influenzae
  – 3 months to 18 years
    o Typical: S. pneumoniae
    o Atypical: C. pneumoniae, M. pneumoniae

RISK FACTORS

• Immunosuppression:
  – Chronic steroid use (>20 mg/day or >2 mg/kg/day of prednisone for >14 days)
  – HIV/immunoglobulin deficiencies/solid organ transplant/TNF-alpha inhibitor therapy

• Chronic health conditions
  – Asthma, COPD
  – Type 2 DM, chronic renal failure, CHF, liver disease, tobacco use

• Other:
  – Age >65 years
  – Antibiotic therapy in the past 6 months/resistance to antibiotics
  – Hospitalization for ≥2 days during past 90 days
  – Poor functional status as defined by activities of daily living score

GENERAL PREVENTION

Vaccination recommendations:

• All children 2 to 59 months of age should be routinely vaccinated with pneumococcal conjugate (PCV13); given at 2, 4, and 6 months of age; a fourth dose at 12 to 15 months of age

• Adults ≥65 years who are vaccine naïve should receive PCV13 followed by pneumococcal polysaccharide (PPSV23) ≥1 year interval.

• For adults ≥65 years old who have already received PPSV23, a dose of PCV13 is indicated after ≥1 year.

• Adults 19 to 64 years with tobacco use, chronic heart or lung disease, alcoholism, or chronic liver disease should receive a dose of PPSV23, followed by PCV13 at age 65 and a subsequent PPSV23 ≥1 year after PCV13 and at least 5 years after the previous PPSV23 dose.

• High-risk adults ≥19 years old with immunocompromising conditions: asplenia, CSF leaks, cochlear implants, HIV infection, immunodeficiencies: 1 dose of PCV13 followed by PPSV23 after ≥8 weeks. A second dose of PPSV23 is recommended for all except those with CSF leak or cochlear implant; it should be given 5 years after first dose. A final dose of PPSV23 should be administered at age 65 and at least 5 years after the previous dose. Those they were previously given PPSV23 should receive a PPCV13 dose ≥1 year after last PPSV23. If additional PPSV23 is required, it should be given ≥8 weeks after PCV13 and 5 years after most recent dose of PPSV23.

• Annual influenza vaccine
DIAGNOSIS

HISTORY
- Fever, chills, rigors, malaise, fatigue
- Dyspnea
- Cough, with/without sputum
- Pleuritic chest pain
- Myalgias
- GI symptoms
- Pediatric patients: lethargy, hypotonia, poor feeding, dry mucus membranes, vomiting

ALERT
- High fever (>104°F [40°C]), male sex, multilobar involvement, and GI and neurologic abnormalities have been associated with CAP caused by Legionella.
- History of advanced neurodegenerative disease or dementia who develop sudden high fever and cough should raise suspicion for aspiration pneumonia.

Geriatric Considerations
Older adults with pneumonia often present with weakness, mental status change, agitation, or history of falls.

PHYSICAL EXAM
- Vitals: fever >100.4°F (38°C), tachypnea, tachycardia, hypoxemia
  - Severe cases may also present with hypothermia, bradycardia, or hypotension
- Pulmonary exam: decreased breath sounds unilaterally with rales, rhonchi, egophony, increased fremitus, bronchial breath sounds, dullness to percussion, asymmetric breath sounds, abdominal tenderness
- Pediatric exam findings: grunting, retractions

DIFFERENTIAL DIAGNOSIS
Bronchitis, asthma or COPD exacerbation, pulmonary edema, lung cancer, pulmonary tuberculosis, pneumonitis, rheumatologic etiologies (i.e., sarcoidosis)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Outpatient setting:
  - Routine laboratory testing to establish an etiology in outpatients with CAP is usually unnecessary
  - Can be diagnosed based on clinical findings of: fever, tachypnea, and physical exam findings chest x-ray does not need to be obtained
- Inpatient, non-critical care setting:
  - CBC, sputum Gram stain, procalcitonin, and two sets of blood cultures prior to antibiotics
  - Chest x-ray
- Inpatient, critical care setting:
  - In addition to above, add Legionella and pneumococcal urinary antigen testing
  - Early in disease course, CXR may be negative
- Evidence of necrotizing/cavitary pneumonia should raise suspicion for MRSA pneumonia,
especially with history of prior MRSA or influenza illness.

**Pediatric Considerations**
- Obtain high sensitivity viral testing including influenza as up to 80% of children under the age of 2 years old will have a viral cause.
- Obtain blood cultures only if no improvement on antibiotics or moderate to severe pneumonia.
- Do not obtain urinary antigen testing due to high false positive rates.

**Diagnostic Procedures/Other**
- For VAP/HAP: By bronchoscopic or nonbronchoscopic means, obtain a lower respiratory tract sample for culture prior to initiation/change of therapy. Serial evaluations may be needed.
- Safe cessation of antibiotics can be done from a good quality negative sputum culture.

**TREATMENT**

**MEDICATION**

**First Line**
- Adults
  - CAP, outpatient
    - No significant differences in efficacy between antibiotic options for adults
    - Previously healthy, no antibiotics in past 3 months
      - Macrolide: Azithromycin 500 mg PO 1 time and then 250 mg PO daily for 4 days; or clarithromycin 500 mg PO BID for 10 days; or erythromycin 500 mg PO BID for 10 days; or
      - Alternative: Doxycycline 100 mg PO BID for 10 days
    - Comorbid conditions, immunosuppressed, antibiotic use in past 3 months
      - Levofloxacin 750 mg PO daily for 5 days; or moxifloxacin 400 mg PO daily for 5 days; or
      - Amoxicillin 1 g PO TID; amoxicillin-clavulanate 2 g PO BID + macrolide/doxycycline for 5 days
    - Treatment may be stopped if
      - Afebrile for >48 hours
      - Supplemental oxygen no longer needed
      - No more than one of the following:
        - HR >100 beats/min
        - RR >24 breaths/min
        - Systolic blood pressure (BP) ≤90 mm Hg
  - CAP, inpatient
    - IV antibiotics initially and then switch to PO after clinical improvement
    - Treatment duration depends on clinical improvement but for a minimum of 5 days
    - Systemic corticosteroids may be beneficial in severe CAP in reducing mortality and morbidity. Studied doses were 40–50 mg daily for 5–10 days (2)
    - Non-ICU
      - Respiratory fluoroquinolone for 5–14 days
      - β-Lactam + macrolide for 5–14 days
      - If Pseudomonas is a consideration
β-Lactam + respiratory fluoroquinolone
β-Lactam + azithromycin
Add pseudomonal or MRSA coverage as above

- HCAP/HAP
  - Use IV antibiotics, treat for 7-day minimum
    - Early onset (<5 days) and no risk factors for multidrug-resistant pathogens
      - Piperacillin-tazobactam, Cefepime, Levofloxacin, Imipenem or Meropenem
    - Late onset (≥5 days) or risk factors for multidrug-resistant pathogens (antibiotic therapy in preceding 90 days, high frequency of antibiotic resistance in community/hospital, immunosuppressive disease/therapy, risk factors for HCAP)
      - MRSA coverage: linezolid or vancomycin + one drug from each group:
        - cefepime, ceftazidime, imipenem, meropenem, or piperacillin-tazobactam
        - Levofloxacin, ciprofloxacin, aztreonam, or aminoglycoside (amikacin, gentamicin, tobramycin) (level II)
      - Drug-resistant S. pneumoniae should be treated with high-dose amoxicillin, amoxicillin/clavulanate, or cefpodoxime with a macrolide, or a respiratory fluoroquinolone

- VAP
  - Use IV antibiotics, recommended minimum duration of therapy is 7 days
  - Use 1 drug from each class in combination:
    - Vancomycin or Linezolid
    - Piperacillin-tazobactam, Cefepime, Ceftazidime, Imipenem, Meropenem, or Aztreonam
    - Ciprofloxacin, Levofloxacin, Amikacin, Gentamicin, Tobramycin, Colistin 5 mg/kg IV for 1 dose and 2.5 mg × (1.5 × CrCl +30) IV q12 for maintenance, or Polymyxin B 2.5–3.0 mg/kg/day IV BID
  - Adult IV antibiotic doses
    - β-Lactams (ampicillin-sulbactam 3 g q6h; aztreonam 2 g q6h; cefepime 1 to 2 g q8–12h; cefotaxime 1 g q6–8h; ceftazidime 2 g q8h; ceftriaxone 2 g daily; imipenem 500 mg q6h; meropenem 1 g IV q8h)
    - Aminoglycosides (amikacin 20 mg/kg daily; gentamicin 7 mg/kg daily; tobramycin 7 mg/kg daily)
    - Fluoroquinolones (levofloxacin 750 mg daily; moxifloxacin 400 mg daily; ciprofloxacin 400 mg q8h)
    - Macrolides (azithromycin 500 mg daily; clarithromycin 500 mg daily; erythromycin 500 to 1,000 mg q6h)
    - Vancomycin 15 mg/kg q12h
    - Linezolid 600 mg q12h
    - Piperacillin-tazobactam 4.5 g q6h
    - Telavancin is an antibiotic, which covers MRSA infection. Telavancin is approved for the treatment of HAP and VAP caused by S. aureus. This medication is indicated only when alternative agents cannot be used.
  - Pediatric, outpatient (≥3 months)
    - Antibiotic treatment in preschool-age children is not routinely required because viral pathogens are more common.
10 days of therapy has been most studied; can consider shorter duration if treating mild pneumonia as an outpatient

 Presumed typical bacterial pneumonia
  - Amoxicillin 90 mg/kg/day PO BID (max 4 g/day)
  - Amoxicillin-clavulanate 90 mg/kg/day PO BID (max 4 g/day)

 Presumed atypical bacterial pneumonia
  - Azithromycin 10 mg/kg PO on day 1 (max 500 mg) and then 5 mg/kg/day (max 250 mg) on days 2 to 5
  - Clarithromycin 15 mg/kg/day PO BID (max 1 g/day)
  - Erythromycin 40 mg/kg/day PO daily
  - Doxycycline 1–2 mg/kg/dose PO BID if >8 years old

 Pediatric, inpatient (≥3 months)
  - Presumed typical bacterial pneumonia
    - Fully immunized: Ampicillin 200 mg/kg/day IV q6 hours
    - Not fully immunized: Ceftriaxone 50–100 mg/kg/day IV q 12–24 hours (max 2,000 mg)
    - Add vancomycin or clindamycin if suspecting community acquired MRSA
  - Presumed atypical bacterial pneumonia
    - Azithromycin 10 mg/kg IV daily on day 1 and 2 (max 500 mg) and then 5 mg/kg/day PO (max 250 mg) on days 3–5
    - Alternatives: Clarithromycin, Erythromycin, Doxycycline (if >8 years old), Levofloxacin (if reached growth maturity)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

 Clinical judgment and use of a validated severity of illness score are recommended to determine if inpatient management is indicated.

 The Pneumonia Severity Index (PSI) is a clinical prediction rule used to calculate the probability of morbidity and mortality among patients with CAP. PSI is risk stratified from I to V. PSI risk class from I to III can be treated as outpatients and IV to V should be hospitalized. PSI can be calculated at https://www.mdcalc.com/psi-port-score-pneumonia-severity-index-cap.

 The CURB-65 or CRB 65 (confusion, urea nitrogen RR, BP, age >65 years) (http://www.mdcalc.com/curb-65-severity-score-community-acquired-pneumonia/) is a severity of illness score for stratifying adults with CAP into different management groups.

 The SMART-COP (systolic BP, multilobar chest radiography, albumin, RR, tachycardia, confusion, oxygen level, and arterial pH) is a new method to predict which patients will require intensive respiratory/vasopressor support. A score of ≥3 has sensitivity of 92% to identify those patients who will receive intensive treatment.

 Patients with COPD or CHF are more likely to require ICU admission when suffering from CAP.

 Clinical prediction tools do not replace a physician’s clinical judgment.

 Other considerations
  - Analgesia and antipyretics
  - Chest physiotherapy
  - IV fluids (and conversely, diuretics) if indicated
  - Pulse oximetry
  - Oxygen supplementation
  - Positioning to minimize aspiration risk
– Respiratory therapy
– Suctioning and bronchial
– Mechanical ventilatory support with low tidal volumes. Systemic support may include proper hydration and nutrition.

**Pediatric Considerations**
- Inpatient treatment of children is recommended in the following settings: infants ≤3 to 6 months; presence of respiratory distress (tachypnea, dyspnea, retractions, grunting, nasal flaring, apnea, altered mental status, \(O_2\) sat <90%); or if known to have CAP as result of a virulent pathogen such as community-associated MRSA
- Discharge criteria: clinical stability for 12–24 hours including: temperature ≤100°F (37.8°C), HR ≤100 beats/min, RR ≤24 beats/min, systolic BP ≤90 mm Hg, \(O_2\) sat ≥90% on room air, ability to maintain oral intake, normal mental status, ability to tolerate antibiotic regimen

**ONGOING CARE**

**PATIENT EDUCATION**
Smoking cessation, vaccinations

**COMPLICATIONS**
Necrotizing pneumonia, respiratory failure, empyema, abscesses, cavitation, bronchopleural fistula, sepsis

**REFERENCES**

**CODES**

**ICD10**
- J15.9 Unspecified bacterial pneumonia
- J15.4 Pneumonia due to other streptococci
- J14 Pneumonia due to Hemophilus influenzae

**CLINICAL PEARLS**
- Bacterial pneumonia can usually be treated empirically based on its classification as CAP or HCAP/HAP/VAP.
- A severity of illness score is helpful in determining the need for hospitalization of adult patients but does not replace a physician’s clinical judgment.
BASICS

DESCRIPTION
- Bronchopulmonary infection caused by the Mycoplasma species, Mycoplasma pneumoniae
- Smallest free-living organism; fastidious and slow-growing; first isolated in cattle in 1898
- Most frequently affects children/young adults but can also occur in the elderly; often causes epidemics in close communities (i.e., skilled nursing facilities)
- Infection may be asymptomatic, most often confined to the upper respiratory tract; however, may progress to pneumonia (5–10%)
- Course is usually acute with an incubation period of 1 to 4 weeks.
- Synonym(s): primary atypical pneumonia (PAP); Eaton agent pneumonia; cold agglutinin–positive pneumonia; walking pneumonia

Geriatric Considerations
The highest rate of intensive care unit admissions for community-acquired pneumonia (CAP) due to M. pneumoniae occurs in seniors.

Pediatric Considerations
- Plays a significant role in pneumonias in children of all ages (Pneumonia <5 years, however, is more commonly viral.)
- Increased incidence of asthma exacerbation in older children
- Infants 3 to 6 months with suspected bacterial pneumonia should be hospitalized.

EPIDEMIOLOGY

Incidence
- Estimated 1 million cases per year in the United States
- Responsible for 20% of CAP requiring hospitalizations annually
- Infection occurs most frequently in fall/winter seasons but may develop year round.

Prevalence
- Predominant sex: male = female
- Predominant age group affected: 5 to 20 years
  - May occur at any age
  - Rare in children <5 years of age
- Responsible for up to 15–20% of all cases of CAP yearly
  - Most common cause of pneumonia in school children and young adults who do not have a chronic underlying condition

ETIOLOGY AND PATHOPHYSIOLOGY
- M. pneumoniae is a short-rod mucosal pathogen, which lacks a cell wall and thus is not visible on Gram stain.
- Can grow under both aerobic and anaerobic conditions
Highly contagious, M. pneumoniae is transmitted primarily by aerosol droplets. Pathogenicity linked to its filamentous tips, which adhere selectively to respiratory epithelial cell membrane proteins with production of \( \text{H}_2\text{O}_2 \) and superoxide radicals, damaging cilia. Many pathogenic features of infection are believed to be immune mediated, not directly induced. Decreased ciliary movement produces prolonged paroxysmal, hacking cough. Incubation period is 2 to 3 weeks.

**Alert**
- Infection by M. pneumoniae has come to be recognized as a worldwide cause of CAP.
- M. pneumoniae infection may worsen asthma symptoms as well as cause wheezing in children without asthma.

**RISK FACTORS**
- Immunocompromised state (e.g., HIV, transplant recipients, chemotherapy)
- Smoking
- Close community living (e.g., military barracks, prisons, hospitals, dormitories, schools, household contacts, skilled nursing facilities)

**General Prevention**
Consider droplet isolation of active cases.

**Commonly Associated Conditions**
- Asthma exacerbations as a result of proinflammatory cytokine release (1)[A]
- Chronic obstructive pulmonary disease

**DIAGNOSIS**

**History**
- Infection may be asymptomatic.
- Gradual onset of headache, malaise, low-grade fever, chills
- Symptoms of upper respiratory infection, including incessant, nonproductive, worsening cough (which may become mildly productive late in the illness); rhinorrhea, pharyngitis, and sinusitis may occur subsequently (2).
- Pneumonia may occur with associated pleural effusion.
- The presence of pleuritic chest pain warrants a higher suspicion of M. pneumoniae (2).
- Extrapulmonary findings may develop in 5–10% of patients, including arthralgias, skin rashes, cervical adenopathy, hemolysis, congestive heart failure (CHF), and cardiac conduction abnormalities.
- Neurologic symptoms develop more commonly in children and may include encephalitis, aseptic meningitis, cranial nerve palsies, cerebellar ataxia, ascending paralysis, and coma (3).
- Persistent cough is common during convalescence; other sequelae are rare.

**Physical Exam**
- Toxicity increases with advancing age or comorbidity.
- Hacking/pertussis-like cough may be present along with fever and lassitude.
- Normal lung findings with early infection, but rhonchi, rales, and/or wheezes may develop
several days later (2)

- Mild pharyngeal injection without exudates
- Minimal/no cervical adenopathy
- Erythematous tympanic membranes or bullous myringitis in patients >2 years of age is an uncommon but unique sign.
- Some patients may develop a pleural friction rub.
- Various exanthems, including erythema multiforme and Stevens-Johnson syndrome

**DIFFERENTIAL DIAGNOSIS**

- Viral/bacterial/fungal pneumonia
- Tuberculosis
- Other atypical pneumonias, including Chlamydia pneumoniae, Chlamydophila psittaci, Coxiella burnetii (Q fever), Francisella tularensis (tularemia), Pneumocystis jiroveci, Legionella pneumophila

**DIAGNOSTIC TESTS & INTERPRETATION**

- M. pneumoniae is typically a clinical diagnosis and treated empirically; however, when specific pathogen testing is indicated, polymerase chain reaction (PCR) is the test of choice (4) [C].
- No clinical or radiographic findings can differentiate between M. pneumoniae and other atypical pneumonia pathogens (Chlamydia/Legionella).

**Initial Tests (lab, imaging)**

- White blood cell count may be normal or elevated.
- Hemolytic anemia has been described but is rare.
- Elevated erythrocyte sedimentation rate (ESR) may be present but is nonspecific.
- Use of procalcitonin levels is limited as the rise in levels is generally more modest for atypical etiologies and may be undetectable for mycoplasma species.
- When available, PCR for M. pneumoniae DNA in nasopharyngeal and throat swabs as well as bronchoalveolar lavage respiratory secretions, CSF, and tissue samples may be the most sensitive and specific.
- CXR shows reticulonodular pattern with patchy areas of lower lobe consolidation, although this is not specific. Small pleural effusion may be present in 10–15% cases.

**Follow-Up Tests & Special Considerations**

- Sputum Gram stains are not helpful because M. pneumoniae lacks a cell wall and cannot be stained.
- M. pneumoniae is difficult to culture and requires 7 to 21 days to grow; culturing is successful in 40–90% of cases but does not provide information to guide treatment, thus infrequently performed.
- Complement fixation serologic assay shows 4-fold rise in IgM antibody titer at 2 to 4 weeks after symptom onset; this is an older technique.
- Positive cold agglutinins (titer of ≥1:128 or rising 4-fold) in 50% of infections but can take 1 to 2 weeks to develop; not sensitive/specific; not routinely recommended
- CT of chest may show a combination of patchy tree-in-bud opacities with segmental ground glass opacities.
TREATMENT

GENERAL MEASURES

- Avoid sick contacts.
- Supportive care indicated, especially for very ill patients
- Treatment is initially empiric and must be comprehensive to cover all likely pathogens in the context of the clinical setting.

ALERT

There is insufficient evidence regarding the efficacy of antibiotics in pediatric patients <24 months of age infected with M. pneumoniae. However, some studies show benefit to treating with a macrolide and amoxicillin to cover M. pneumoniae in addition to other likely agents causing CAP (1)[A].

Pregnancy Considerations

- Azithromycin: pregnancy Category B (preferred treatment)
- Clarithromycin, levofloxacin, and moxifloxacin: pregnancy Category C

MEDICATION

First Line

- Azithromycin
  - <3 months of age: not established (5)[B]
  - >3 months of age: day 1, 10 mg/kg PO × 1 (not to exceed 500 mg); days 2 to 5: 5 mg/kg PO daily (not to exceed 250 mg/day)
  - Adults: 500 mg PO × 1 followed by 250 mg PO daily × 4 days
- Doxycycline
  - Children <8 years of age: not recommended
  - Children >8 years of age (≤45 kg): 2 to 4 mg/kg/day up to 200 mg/day PO divided BID for 10 to 14 days
  - Children >8 years of age (≥45 kg): Refer to adult dosing.
  - Adults: 100 mg PO BID × 7 to 14 days
  - Useful in macrolide-resistant strains of M. pneumoniae
- Clarithromycin
  - Children <6 months of age: not established
  - Patients >6 months of age: 15 mg/kg/day PO divided q12h for 10 to 14 days
  - Adults: 250 to 500 mg PO BID for 10 to 14 days
- Minocycline
  - 200 mg PO/IV × 1 dose and then 100 mg BID for 7 to 10 days
- Erythromycin
  - Children: 20 to 50 mg/kg/day (base) PO divided q6–8h for 10 to 14 days
  - Adults: 500 mg (base) PO q6h × 10 to 14 days

Second Line

- Levofloxacin
– Children <18 years of age: not recommended
– Adults: 750 mg PO daily × 5 days

- Moxifloxacin
  – Children <18 years of age: not recommended
  – Adults: 400 mg/day PO for 7 to 10 days

- Levofoxacin and moxifloxacin show good activity against M. pneumoniae. Consider use with comorbid conditions and other pneumonia pathogens; also useful if macrolide resistance is suspected

ADDITIONAL THERAPIES
- Albuterol inhaler: 2 puffs q4–6h as needed for wheezing
- Dexamethasone may downregulate cytokine release (6)[B].
- Acetaminophen/ibuprofen as needed for fever
- Supplemental oxygen as needed
- Up to 10.9% of hospitalized patients may require mechanical ventilation.
- Plasmapheresis in cases of severe hemolytic anemia

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- CAP score risk class IV/V
- Other scoring systems such as the CURB65 and Pneumonia Severity Index (PSI) may also be helpful in the inpatient versus outpatient treatment decision (6)[A].
- Advanced age with comorbidities
- Complicating neoplastic disease
- Significant cerebrovascular, cardiac, renal, liver, or gastrointestinal symptoms
- Altered mental status
- Inability to maintain oxygen saturation
- Tachycardia/tachypnea
- Hypotension
- Neurologic symptoms
- Signs of Stevens-Johnson syndrome
- Significant hemolysis (autoimmune hemolytic anemia, cold agglutinin disease)
- Change from IV to PO antibiotic may be made when:
  – Respiratory distress and hypoxia have resolved.
  – Patients are tolerating oral hydration.
  – No significant complications are present.
  – Utilization of procalcitonin (PCT) may aid in this decision (4)[A].
- Generally, no need for 24-hour observation on PO antibiotics prior to discharge

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Clearing of condition on chest x-ray (CXR) should be documented in patients >50 years of age.
- In smokers, document a clear CXR in 6 to 8 weeks.
- Worsening symptoms/development of rash or meningeal/neurologic signs should prompt immediate presentation to medical attention.
Antibiotic prophylaxis for exposed contacts is not routinely recommended. For household contacts who may be predisposed to severe mycoplasmal infection, macrolide or doxycycline prophylaxis should be used.

**DIET**
- No special diet considerations
- Ensure adequate hydration.

**PATIENT EDUCATION**
- Smoking cessation
- Contact and droplet precautions
- Adequate hand-washing techniques

**PROGNOSIS**
- Symptoms usually resolve in 2 weeks.
- Some constitutional symptoms may persist for several weeks.
- With correct therapy, even most severe cases can expect complete recovery.

**COMPLICATIONS**
- All complications are rare, except reactive airway disease, hemolytic anemia, and erythema multiforme.
- Reactive airway disease may persist indefinitely and can cause acute chest syndrome in patients with sickle cell anemia.
- Meningoencephalitis
- Aseptic meningitis
- Peripheral neuropathy
- Transverse myelitis/acute transverse myelitis
- Cerebellar ataxia
- Acute disseminated encephalomyelitis
- Guillain-Barré syndrome
- Encephalitis (especially in children)
- Polyneuritis/polyarthritis
- Stevens-Johnson syndrome
- Pericarditis/myocarditis
- Respiratory distress syndrome
- Cerebral ataxia
- Thromboembolic phenomena
- Pleural effusion
- Nephritis
- Occasional deaths occur primarily among the elderly and persons with sickle cell disease.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
J15.7 Pneumonia due to Mycoplasma pneumoniae

CLINICAL PEARLS

- Most common atypical respiratory pathogens include M. pneumoniae, C. pneumoniae, and L. pneumophila.
- Atypical pneumonia is usually a clinical diagnosis.
- Watch closely for complicating symptoms that could indicate worsening disease.
- Atypical pneumonia with M. pneumoniae usually responds to empiric treatment.
- Outbreaks of M. pneumoniae can be seen in close communities (i.e., dormitories).
- Presentation of infection is typically a gradual onset of symptoms.
PNEUMONIA, PNEUMOCYSTIS JIROVECI
Thomas J. Hansen, MD, FAAFP

BASICS

DESCRIPTION
- Pneumocystis jiroveci causes pneumonia primarily in immunocompromised patients.
- The fungus that causes this pneumonia in humans was previously called Pneumocystis carinii.
- The name was formally changed to Pneumocystis jiroveci in 2001, following the discovery that the fungus that infects humans is unique and distinctive from the fungus that infects animals.
- P. jiroveci is extremely resistant to traditional antifungal agents, including both amphotericin and azole agents.
- To prevent confusion, the term PCP, which used to represent P. carinii pneumonia, now represents Pneumocystis pneumonia (1).

ALERT
No combination of symptoms, signs, blood chemistries, or radiographic findings is diagnostic of P. jiroveci pneumonia (2).

EPIDEMIOLOGY
- P. jiroveci has a worldwide distribution, and most children have been exposed to the fungus by 2 to 4 years (3).
- The reservoir and mode of transmission for P. jiroveci is still unclear.
  – Human studies favor an airborne transmission model, with person-to-person spread being the most likely mode of infection acquisition (2).

Incidence
- Infants with HIV infection have a peak incidence of PCP between 2 and 6 months (3).
- HIV-infected infants have a high mortality rate, with a median survival of only 1 month.

Prevalence
- The prevalence of P. jiroveci colonization among healthy adults is 0–20%.
- Recent studies have demonstrated the transient nature of P. jiroveci colonization in asymptomatic, immunocompetent patients (2).
- 50% of patients with PCP are coinfected with ≥2 strains of P. jiroveci (3).
- There is evidence that distinct strains are responsible for each episode in patients who develop multiple episodes of PCP (3).

ETIOLOGY AND PATHOPHYSIOLOGY
Mode of transmission is unknown; likely respiratory from infected host

RISK FACTORS
Individuals at risk (2):
- Patients with HIV infection, especially if not receiving prophylactic treatment for PCP
- Patients who are receiving high doses of glucocorticoids
- Patients who have an altered immune system not due to HIV
Patients who are receiving chronic immunosuppressive medications
Patients who have hematologic or solid malignancies resulting in malignancy-related immune depression

GENERAL PREVENTION

Indications for prophylaxis
- HIV-infected adults (3)
  - Should start when CD4 count is <200 cells/μL or if the patient develops oropharyngeal candidiasis
- HIV-infected children (3)
  - Prophylaxis should be provided for children ≥6 years based on adult guidelines.
  - For children ages 1 to 5 years, start when CD4 count is <500 cells/μL.
  - For infants <12 months, start when the CD4 percentage is <15%.
- Non–HIV-infected adults receiving immunosuppressive medications or with underlying immune system deficits should receive PCP prophylaxis, but currently, there are no specific guidelines on when to start this.

Medication
- Trimethoprim-sulfamethoxazole (TMP-SMX)
  - Adults: 1 double-strength tablet daily or 1 double-strength tablet 3 times per week
  - Children >2 months: TMP 150 mg/kg/day in divided doses q12h for 3 days/week
- Atovaquone suspension
  - Adults: 1,500 mg PO once daily with food
  - Children: not to exceed 1,500 mg/day
    - 1 to 3 months: 30 mg/kg/day PO once daily
    - 4 to 24 months: 45 mg/kg/day PO once daily
    - >24 months: 30 mg/kg/day PO once daily
    - Adolescents ≥13 years: Refer to adult dosing.
- Dapsone
  - Adults only: 50 mg BID or 100 mg once daily
- Pentamidine
  - Adults only: 300 mg aerosolized every 4 weeks

Discontinuation of prophylaxis
- When CD4+ cell counts are >200 cells/μL for a period of 3 months in the adult population
- There are no clear guidelines for discontinuation of prophylaxis in children.

COMMONLY ASSOCIATED CONDITIONS

- HIV Infection
- Chronic obstructive pulmonary disease (COPD)
- Interstitial lung disease
- Connective tissue diseases treated with corticosteroids
- Cancer and organ transplant patients on immunosuppressive medication

DIAGNOSIS

HISTORY
- HIV-infected patients
– Subacute onset over several weeks
  o Progressively worsening dyspnea
  o Tachypnea
  o Cough: nonproductive or productive of clear sputum
  o Low-grade fever, chills
  o Weakness, fatigue, malaise
• Non–HIV-infected immunocompromised patients
  – More acute onset with fulminant respiratory failure
    o Abrupt tachypnea, dyspnea
    o Fever
    o Dry cough

PHYSICAL EXAM
• Fever
• Tachypnea
• Tachycardia
• Lung exam is normal or near normal.

DIFFERENTIAL DIAGNOSIS
• Tuberculosis
• Bacterial pneumonia
• Fungal pneumonia
• Viral pneumonia

DIAGNOSTIC TESTS & INTERPRETATION
P. jiroveci cannot be cultured. Therefore, a diagnosis relies on detection of the organism by
colorimetric or immunofluorescent stains or by polymerase chain reaction (PCR) (3)[C].
• ABG: reveals hypoxemia and increased alveolar-arterial gradient that varies with severity of
disease
• LDH: Serum lactate dehydrogenase is frequently increased (nonspecific; likely due to
underlying lung inflammation and injury).
• CD4 cell count is generally <200 cells/μL in HIV-infected patients with PCP.
• S-adenosylmethionine levels are significantly lower in a patient with PCP. The levels increase
with successful treatment (4)[B].
• Comprehensive metabolic profile
• Chest x-ray (CXR) (2)[C]
  – Bilateral, symmetric, fine, reticular interstitial infiltrates involving perihilar areas; becomes
more homogeneous and diffuse as severity of infection progresses
  – Less common patterns include upper lobe involvement in patients receiving aerosolized
pentamidine, solitary or multiple nodular opacities, lobar infiltrates, pneumatoceles, and
pneumothoraces.
  – May be normal in up to 30% of patients with PCP (1)[C]
• High-resolution CT is more sensitive than CXR.

Diagnostic Procedures/Other
• Fiberoptic bronchoscopy with bronchoalveolar lavage (BAL) is the preferred diagnostic
procedure to obtain samples for direct fluorescent antibody staining.
  – Sensitivities range from 89% to >98%.
• Pneumocystis trophic forms or cysts obtained from induced sputum, BAL fluid, or lung tissue, which can be visualized using conventional stains
• PCR can detect Pneumocystis from respiratory sources, but the potential remains for false positives (2)[C].

**TREATMENT**

The recommended duration of therapy differs in patients who are with/without AIDS:
• In patients with PCP who do not have AIDS, the typical duration of therapy is 14 days.
• Treatment of PCP in patients who have AIDS was increased to 21 days due to the risk for relapse after only 14 days of treatment (2)[C].

**MEDICATION**

• TMP-SMX (2)[C]
  • Adult dosing
    – TMP: 15 to 20 mg/kg/day, PO or IV, divided into 4 doses
  • Pediatric dosing (>2 months) (2)[C]
    – TMP: 15 to 20 mg/kg/day in divided doses q6–8h
• Reduce doses of TMP-SMX in patients with renal failure.
• Patients should receive 21 days of therapy.
• Treatment response to Pneumocystis therapy often requires at least 7 to 10 days before clinical improvement is documented.
• Pregnancy risk factor: category C (2)[C]
• Precautions
  – History of sulfa allergy
  – There is an emergence of drug-resistant PCP, especially against TMP-SMX.

**Second Line**

• Pentamidine (for moderate to severe cases)
  – Adults and children: 4 mg/kg IV or IM once daily
• Dapsone + trimethoprim (adults only)
  – Dapsone 100 mg PO once daily, plus
  – Trimethoprim 5 mg/kg PO TID
    – Check the glucose-6-phosphate dehydrogenase level before beginning dapsone because hemolysis may result.
• Clindamycin + primaquine (adults only)
  – Clindamycin 600 to 900 mg IV q8h or 300 to 450 mg PO QID, plus
  – Primaquine 30 mg PO once daily
• Atovaquone
  – Adults: 750 mg PO BID (>13 years of age)
  – Children: 40 mg/kg/day PO divided BID (max 1,500 mg)
• Note: Pentamidine has greater toxicity than TMP-SMX: hypotension, hypoglycemia, pancreatitis (2)[C].

**ADDITIONAL THERAPIES**

• Adjunctive corticosteroid (prednisone or methylprednisolone) (2)[C],(5)[A]
  • Adjunctive corticosteroids are shown to provide benefits in patients who have HIV and
symptoms of moderate to severe PCP.

- Corticosteroids provide the greatest benefit to HIV patients who have hypoxemia manifested as a partial pressure of arterial oxygen <70 mm Hg or an alveolar–arterial gradient >35 mm Hg on room air.
- Adults and children >13 years of age: prednisone, 40 mg PO BID on days 1 to 5; 40 mg daily on days 6 to 11; 20 mg daily on days 12 to 21

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- No set criteria for hospital admission
- Five predictors of mortality in HIV-associated Pneumocystis pneumonia (6)
  - Increased age of the patient
  - Recent IV drug use
  - Total bilirubin >0.6 mg/dL
  - Serum albumin <3 g/dL
  - Alveolar-arterial oxygen gradient ≥50 mm Hg (6)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

In patients with HIV/AIDS: Patients with previous episodes of PCP should receive lifelong secondary prophylaxis unless they respond well to highly active antiretroviral therapy (HAART) and have a CD4 count >200 cells/μL for at least 3 months.

Patient Monitoring
Serum lactate dehydrogenase levels, pulmonary function test results, and ABG measurements generally normalize with treatment.

DIET
No special diet needed

PATIENT EDUCATION

- Centers for Disease Control and Prevention: https://www.cdc.gov/dpdx/pneumocystis/index.html

REFERENCES

ADDITIONAL READING

SEE ALSO

HIV/AIDS

CODES

ICD10

B59 Pneumocystosis

CLINICAL PEARLS

- Colonization with P. jiroveci is common in the pediatric population.
- PCP only occurs in immunocompromised patients.
- Patients with HIV are at risk once their CD4 count is <200 cells/μL. At that time, TMP-SMX should be initiated as prophylaxis. Prophylaxis may end after HAART has been initiated and the CD4 count is >200 cells/μL for 3 months.
Patients who are immunocompromised are also at risk. Currently, no clear clinical guidelines are available as to when to initiate or end prophylaxis.

The first-line treatment is TMP-SMX. The typical duration of therapy is 14 days in non–HIV-infected patients and 21 days in HIV-infected patients.
POLYARTERITIS NODOSA
Katherine S. Upchurch, MD, MACR ● Stephen Morais, MD, MBA, MS

BASICS

DESCRIPTION

Polyarteritis nodosa (PAN) is an antineutrophil cytoplasmic antibody (ANCA)-negative necrotizing arteritis of medium-sized muscular arteries and (occasionally) small arteries. Arterioles, capillaries, and venules are spared (1).

Involved systems include gastrointestinal (GI) tract, peripheral nervous system (sensory and motor), CNS, genitourinary, skin, and cardiovascular. Glomerulonephritis and pulmonary capillaritis are rare (1,2).

Features depend on location of vasculitis: for example, mesenteric ischemia–related symptoms, new onset or worsening hypertension (HTN), mononeuritis multiplex, purpuric or nodular skin lesions, or livedo reticularis (2).

Renal disease in PAN usually manifests as HTN and mild proteinuria with/without azotemia. Renal infarction may also occur (2).

PAN formerly encompassed several distinct entities (classic PAN, microscopic PAN, and cutaneous PAN). With ANCA testing, microscopic PAN appears pathophysiologically unrelated to the other two.

- Idiopathic generalized PAN (classic PAN) is clinically variable, ranging from single organ involvement to polyvisceral failure (1).
- HBV-associated PAN patients are positive for active hepatitis B infection and can present in similar fashion to idiopathic generalized PAN (1).
- Microscopic PAN has ANCAs directed against myeloperoxidase (MPO) and involvement of small arterioles (microscopic polyangiitis [MPA]). This is now classified as ANCA-associated vasculitis.
- Cutaneous (or limited) PAN is generally limited to the deep dermal and subcutaneous (SC) levels of the skin with characteristic histopathologic features of PAN. There are few systemic manifestations, although myalgias and peripheral motor neuropathy (mononeuritis multiplex) or sensory neuropathy may be present (2,3).

Synonym(s): periarteritis; panarteritis; necrotizing arteritis

EPIDEMIOLOGY

Incidence

- Predominant age: peaks in 5th to 6th decade; incidence rises with age.
- Mean age at diagnosis is 50 years (3).
- 1.5:1 male predominance

Prevalence

Rare: 2 to 33 cases per 1 million adults (3)

ETIOLOGY AND PATHOPHYSIOLOGY

- Segmental, transmural, necrotizing inflammation of medium and small muscular arteries, with
intimal proliferation, thrombosis, and ischemia of the end-organ/tissue supplied by the affected vessels; aneurysm formation at vessel bifurcations (2)

- Hepatitis B–related PAN results in direct vessel injury due to viral replication or deposition of immune complexes, with complement activation and subsequent inflammatory response (2).
- Most cases are idiopathic; 20% are related to hepatitis B or C infection.
- In patients with PAN and hepatitis B, HBsAg has been recovered from involved vessel walls.

Genetics

Mutations of adenosine deaminase 2 (ADA 2) have been identified in families with PAN (1).

RISK FACTORS

Hepatitis B > hepatitis C infection (cutaneous PAN)

COMMONLY ASSOCIATED CONDITIONS

- Hepatitis B (strong association with classic PAN)
- Hepatitis C (less strongly linked to cutaneous PAN)
- Hairy cell leukemia
- 27 cases of systemic PAN following hepatitis B vaccination
- Minocycline (Symptoms resolve on stopping drug, reoccur if rechallenged.)
- Case-based associations with CMV infection, amphetamines, and interferon

DIAGNOSIS

- There are no formal diagnostic criteria for PAN (1,2).
- Suspect PAN with:
  - Acute, sometimes fulminant multisystem disease with a relatively short prodrome (i.e., weeks to months)
  - Vasculitic skin rash with sensorimotor symptoms/findings
  - Recent-onset HTN with systemic symptoms
  - Unexplained sensory and/or motor neuropathy with systemic symptoms
  - Hepatitis B infection with multisystem disease

HISTORY

Symptoms reflect specific organ involvement (2).
- Constitutional symptoms (fever, weight loss, malaise)
- Organ-specific symptoms
  - Focal muscular weakness/extremity numbness
  - Myalgia and arthralgia
  - Rash
  - Recurrent postprandial pain, intestinal angina, nausea, vomiting, and bleeding
  - Altered mental status, headaches, mononeuritis multiplex
  - Testicular/epididymal pain, neurogenic bladder (rare)

PHYSICAL EXAM

Findings/course reflect specific organ involvement (2).
- Peripheral nervous system: peripheral neuropathy
- Renal: HTN
- Skin: purpura, urticaria, polymorphic rashes, SC nodules (uncommon but characteristic),
livedo reticularis; deep skin ulcers, especially in lower extremities; Raynaud phenomenon (rare); single digit gangrene (rare)

- GI: acute abdomen; rebound, guarding, tenderness
- CNS: seizures, altered mental status, papillitis
- Lung: signs of pleural effusion—dullness to percussion; decreased breath sounds
- Cardiac: signs of congestive heart failure and/or myocardial infarction—$S_3$ gallop; pericarditis (Friction rub is rare.)
- Genitourinary: testicular/epididymal tenderness (can mimic testicular torsion)
- Musculoskeletal: arthritis (usually large joint in lower extremities)

**DIFFERENTIAL DIAGNOSIS**

- Other forms of vasculitis (ANCA-associated, such as granulomatosis with polyangiitis [GPA—formerly Wegener granulomatosis], Churg-Strauss syndrome, and MPA; Henoch-Schönlein purpura, drug-induced vasculitis, cryoglobulinemia, Goodpasture syndrome)
- Buerger disease
- Systemic lupus erythematosus (SLE)
- Embolic disease (atrial myxoma, cholesterol emboli)
- Thrombotic disease (antiphospholipid antibody syndrome)
- Dissecting aneurysm
- Ehlers-Danlos syndrome
- Multiple sclerosis, systemic amyloidosis
- Infection (subacute endocarditis, HIV infection, trichinosis, rickettsial diseases)
- Fibromuscular dysplasia
- Ergotamine use
- Segmental arterial mediolysis

**DIAGNOSTIC TESTS & INTERPRETATION**

- No specific laboratory abnormalities. Confirm diagnosis with biopsy if possible (4)[A].
- Angiography (conventional, CT angiography, or MR angiography) may reveal microaneurysms and/or beading of bifurcating blood vessels.
- Avoid contrast in renal disease.
- Nonspecific laboratory abnormalities:
  - Elevated ESR and CRP
  - Mild proteinuria, elevated creatinine
  - Hepatitis B surface antigen positive in 10–50%
  - Hepatitis C antibody/hepatitis C virus RNA
  - ANCA, anti-proteinase 3 (PR3), and anti-MPO are negative. Positive ANCA argues against PAN.
  - Rheumatoid factor may be positive.
  - Anemia of chronic disease (2,4)

**Initial Tests (lab, imaging)**

Look for evidence of systemic disease and rule out other causes (2,4):

- CBC, ESR, CRP (elevated) (4)[C]
- Chemistries: elevated creatinine/BUN (4)[C]
- Hepatitis B serology: often positive; hepatitis C less commonly positive
- LFTs: abnormal if associated hepatitis B, C, or involvement of hepatobiliary tract
Urinalysis: proteinuria/hematuria, generally no cellular casts or active urinary sediment (4)[C]
ANA, cryoglobulins (4)[C]
ANCA, anti-MPO, and anti-PR3 (4)[A]
Complement levels (C3, C4)
Angiographic demonstration of aneurysmal changes/beading of small and medium-sized arteries

Diagnostic Procedures/Other
- Electromyography and nerve conduction studies in patients with suspected mononeuritis multiplex. If abnormal, consider sural nerve biopsy.
- Arterial/tissue biopsy
- Skin biopsy from edges of ulcers; include deep dermis and SC fat to assess small muscular artery involvement (excisional not punch biopsy) (2,4).

Test Interpretation
- Necrotizing inflammation with fibrinoid necrosis of small and medium-sized muscular arteries; segmental, often at bifurcations and branchings. Venules are not involved in classic PAN.
- Capillaritis/other lung parenchymal involvement by vasculitis strongly suggests another process (microscopic PAN, GPA, Churg-Strauss syndrome, or antiglomerular basement membrane disease).
- Acute lesions with infiltration of polymorphonuclear cells through vessel walls into perivascular area; necrosis, thrombosis, infarction of involved tissue
- Aneurysmal dilatations, including aortic dissection
- Peripheral nerves: 50–70% (vasa nervorum with necrotizing vasculitis)
- GI vessels: 50% (at autopsy) with bowel necrosis; gallbladder and appendix vasculature: 10%
- Muscle vessels: 50%
- Testicular vessels involved in symptomatic males
- The key differences from other necrotizing vasculitides are lack of granuloma formation and sparing of veins and pulmonary arteries (2).

TREATMENT
GENERAL MEASURES
Treat HTN aggressively to prevent complications (stroke, myocardial infarction, heart failure).

MEDICATION
First Line
- Severe (life-threatening) disease: corticosteroids (CS) (high-dose oral prednisone [1 mg/kg/day] or intravenous [IV] methylprednisolone [0.5 to 1.0 g/day] for 3 days, then transition to prednisone 1 mg/kg/day, and taper according to response) (4,5)[A]
  - Only 50% of patients achieve and maintain remission with CS. Other patients require additional immunosuppressive therapy.
  - IV cyclophosphamide (0.6 g/m² every 2 weeks for 3 doses and then monthly for 4 to 12 months) in combination with CS: improves survival and spares use of chronic steroids in moderate/severe PAN (4,5)[A]
    - Cyclophosphamide has risk of infertility and malignancy.
– Plasma exchange for severe refractory disease, such as progressive renal disease (4)[A]

Less severe disease: CS alone ± other immunosuppressive agents (azathioprine 2 mg/kg/day, methotrexate 20 to 25 mg/week, mycophenolate mofetil 2,000 to 3,000 mg daily).
Hydroxychloroquine (5 mg/kg/day) use has been reported (4,5)[A],[6][C].

– Cutaneous PAN: Nonsteroidal anti-inflammatory drugs, dapsone, and colchicine are used (4)[C].

– HBV-associated PAN: antiviral agents, short-term CS, plasma exchange (1,3)[C]

**Second Line**

– There is no well-defined second-line therapy in PAN.

– Infliximab (3 to 5 mg/kg IV at 0, 2, and 6 weeks, and every 4 to 8 weeks thereafter) and rituximab (1,000 mg IV on days 0 and 14 and then every 6 months OR 375 mg/m² IV weekly for 4 weeks) anecdotally reported to be of benefit in refractory PAN (3,4)[C].

**ADDITIONAL THERAPIES**

– For patients receiving IV cyclophosphamide, mercaptopethanesulfonate reduces bladder exposure to carcinogenic metabolites (4).

– Prophylactically treat patients on cyclophosphamide for Pneumocystis jiroveci (carinii) pneumonia with trimethoprim-sulfamethoxazole (use dapsone 100 mg/day or atovaquone 1,500 mg/day in intolerant/allergic patients) (4).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Depends on extent and involvement of specific organs

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

– CBC, urinalysis, renal and hepatic function tests

– Acute-phase reactants (e.g., ESR, CRP) may help monitor disease activity.

– The revised 2009 Five Factor Score (FFS) can predict mortality and guide treatment strategies.

– Four factors are used in the evaluation of patients with PAN, including age, renal insufficiency, cardiac involvement, and GI manifestations. The fifth factor, ENT manifestations, is only applied to patients with ANCA-associated vasculitis (1,3).

– Be alert for:
  – Side effects of immunosuppressant medications
  – Delayed appearance of neoplasms, especially bladder malignancy in patients treated with cyclophosphamide (Check annual U/A, urinary cytology with urologic evaluation if microscopic hematuria.) (3)[C]
  – Steroid-induced osteoporosis

**DIET**

– Low-salt diet (HTN)

– Mediterranean diet for cardiovascular health

– Calcium and vitamin D–rich diets for patients on CS therapy

**PATIENT EDUCATION**
ACR website: https://www.rheumatology.org

PROGNOSIS

- Expected outcome of untreated PAN is poor.
- Steroid and cytotoxic treatment increases 5-year survival rate to 75–80% (2).
- Survival is greater for hepatitis B–related PAN as a result of the introduction of antiviral treatments.
- Patients presenting with proteinuria, renal insufficiency, GI tract involvement, cardiomyopathy, or CNS involvement have a worse prognosis.

COMPLICATIONS

- End-organ damage from ischemia
- Complications from immunosuppressive agents

REFERENCES

ADDITIONAL READING

SEE ALSO

Hepatitis B; Hepatitis C

CODES

ICD10
- M30.0 Polyarteritis nodosa
- M30.1 Polyarteritis with lung involvement [Churg-Strauss]
- M30.8 Other conditions related to polyarteritis nodosa

**CLINICAL PEARLS**

- PAN is a necrotizing vasculitis of small- to medium-sized muscular arteries with lack of granuloma formation that spares veins and pulmonary arteries.
- Clinical features of PAN depend on target organ.
- Skin biopsies at ulcer edges (include deep dermis and SC fat) improve diagnostic yield.
- Check hepatitis B and C serologies.
- ANCA is negative in classic PAN.
- At diagnosis, the revised FFS can determine prognosis and guide therapy.
- Treatment involves use of immunosuppressive drugs; choice depends on extent and severity of disease.
POLYCYSTIC KIDNEY DISEASE
Maricarmen Malagon-Rogers, MD

BASICS

DESCRIPTION
- A group of monogenic disorders that results in renal cyst development
- The most frequent are two genetically distinct conditions: autosomal dominant polycystic kidney disease (ADPKD) and autosomal recessive polycystic kidney disease (ARPKD).
- ADPKD is one of the most common human genetic disorders.

EPIDEMOLOGY
- ADPKD is generally late onset.
  - Mean age of end-stage kidney disease (ESKD) 57 to 69 years
  - More progressive disease in men than in women
  - Up to 90% of adults have cysts in the liver.
- ARPKD usually present in infants
  - A minority in older children and young adults may manifest as liver disease.
  - Nonobstructive intrahepatic bile dilatation is sometimes seen.
  - Found on all continents and in all races

Incidence
- Mean age of ESKD: PKD1 mutation, 54.3 years versus PKD2 mutation, 74 years
- ARPKD affects 1/20,000 live births; carrier level is 1/70.
- ADPKD affects 1/400 to 1,000 live births.

Prevalence
As ESKD, ADPKD: 8.7/1 million in the United States; 7/1 million in Europe

ETIOLOGY AND PATHOPHYSIOLOGY
- ADPKD
  - PKD1 and PKD2 mutations disrupt the function of polycystins on the primary cilium, forming fluid-filled cysts that progressively increase in size, leading to gross enlargement of the kidney and distortion of the renal architecture.
  - Glomerular hyperfiltration compensates for the progressive loss of healthy glomeruli, and therefore, by the time GFR decline becomes detectable, as much as half of the original functional glomeruli are irreversibly lost.
  - The majority of patients with ADPKD ultimately progress to ESKD (1).
- ARPKD
  - PKHD1 product fibrocystin is also located in cilia.
- ARPKD: Cysts arise from only 5% of nephrons:
  - Autosomal dominant pattern of inheritance but a molecularly recessive disease with the 2-hit hypothesis
  - Requires genetic and environmental factors
- ARPKD: Mutations are scattered throughout the gene with genotype–phenotype correlation.
Genetics

- **ADPKD**
  - Autosomal dominant inheritance
  - 50% of children of an affected adult are affected.
  - 100% penetrance; genetic imprinting and genetic anticipation are seen as well.
  - Two genes isolated
    - PKD1 on chromosome 16p13.3 (85% of patients) encodes polycystin 1.
    - PKD2 on chromosome 4q21 (15% of patients) encodes polycystin 2.
- **ARPKD**
  - Autosomal recessive inheritance
  - Siblings have a 1:4 chance of being affected; gene PKHD1 on chromosome 6p21.1–p12 encodes fibrocystin.

RISK FACTORS

- Large inter- and intrafamilial variability
- A more rapidly progressive clinical course is predicted by onset of ESKD at <55 years, development of stage III CKD at <40 years old, onset of hypertension (HTN) at <18 years, total kidney volume greater than the expected for a given age, or presence of multiple complications (gross hematuria, microalbuminuria) (1).

GENERAL PREVENTION

Genetic counseling

COMMONLY ASSOCIATED CONDITIONS

- **ADPKD**
  - Cysts in other organs
    - Polycystic liver disease in 58% of young age group to 94% of 45-year-olds
    - Pancreatic cysts: 5%
    - Seminal cysts: 40%
    - Arachnoid cysts: 8%
  - Vascular manifestations
    - Intracerebral aneurysms in 6% of patients without family history and in 16% with family history
    - Aortic dissections
  - Cardiac manifestations: mitral valve prolapse: 25%
  - Diverticular disease
- **ARPKD**: liver involvement: affected in inverse proportion to renal disease; congenital hepatic fibrosis with portal HTN

DIAGNOSIS

HISTORY

- **ADPKD**
  - Positive family history (15% are de novo mutations.)
  - Flank pain: 60%
  - Hematuria
– Urinary tract infection (UTI)
– HTN: 50% ages 20 to 34 years; 100% with ESKD
– Renal failure
– Presymptomatic screening of ADPKD is not currently recommended for at-risk children (2).
  o Blood pressure should be routinely measured in these patients.

- ARPKD
  – 30% of affected neonates die:
    o Enlarged echogenic kidneys and oligohydramnios are diagnosed in utero.
    o Later in childhood: HTN
  – Adolescents and adults present with complications of portal HTN: esophageal varices
  – Hypersplenism

**PHYSICAL EXAM**
- HTN
- Flank masses

**DIFFERENTIAL DIAGNOSIS**
- ADPKD and ARPKD
- Tuberous sclerosis: prevalence 1/6,000
- Von Hippel-Lindau syndrome: prevalence 1/36,000
- Nephronophthisis: accounts for 10–20% of cases of renal failure in children; medullary cystic kidney disease
- Renal cystic dysplasias: multicystic dysplastic kidneys: grossly deformed kidneys; most common type of bilateral cystic diseases in newborns (prevalence: 1/4,000)
- Simple cysts: most common cystic abnormality
  – Localized or unilateral renal cystic disease
  – Medullary sponge kidney
  – Acquired renal cystic disease
- Renal cystic neoplasms: benign multilocular cyst (cystic nephroma)

**DIAGNOSTIC TESTS & INTERPRETATION**
Electrolytes, BUN/creatinine, urine analysis plus urinary citrate

**Initial Tests (lab, imaging)**
- ADPKD
  – Renal dysfunction
    o Impaired renal concentration (3), hypocitraturia aciduria
    o Hyperfiltration
    o Elevated creatinine
  – Urinalysis: hematuria and mild proteinuria
- ARPKD
  – Electrolyte abnormalities and renal insufficiency
  – Anemia, thrombocytopenia, leukopenia
- ADPKD
  – US: It is the easiest diagnostic method; however, it is suboptimal for disease exclusion at age <40 years (2)[C].
    o Renal enlargement is universal.
    o In at-risk patients: By age 30 years, two renal cysts (bilateral or unilateral) are 100%
diagnostic. In children, it sometimes appears similar to ARPKD; may be diagnosed in utero
- Presence of hepatic cysts in young adults is pathognomonic for ADPKD.
- In the absence of family history, bilateral renal enlargement and cysts make the diagnosis.
  - CT scan/MRI ideally should be part of the initial evaluation [2][C].
  - Kidney volume assessed by CT scan or MRI is a main predictor of progression.
  - Helpful in identifying cysts in other organs
  - In subjects <40 years, fewer than five cysts by MRI excludes the diagnosis [2][B].

**ARPKD**
- US: Kidneys are enlarged, homogeneously hyperechogenic (cortex and medulla).
- CT scan is more sensitive if diagnosis is in doubt.
- Presence of hepatic fibrosis helps the diagnosis.

### Follow-Up Tests & Special Considerations
- Diagnosis and prevention of secondary problems because of renal and liver abnormalities
- Follow-up of combined renal volume to assess disease severity
- Beyond age 2 years, renal size decreases in ARPKD but continues to grow in ADPKD at an average rate of 5.27% per year. Total kidney volume identifies patients with progressive disease [2].

### Diagnostic Procedures/Other
- Genetic testing is available for **PKD1** and **PKD2** in ADPKD when imaging results are equivocal and for potential living related donors [4][C].
- For **PKHD1** in ARPKD, a prenatal diagnosis is feasible in about 72% of patients.

### Test Interpretation
- **ADPKD**
  - Kidneys are diffusely cystic and, although enlarged, retain their general shape.
  - Cysts range from a few millimeters to several centimeters and are distributed evenly throughout the cortex and medulla.
  - They arise in all segments of the nephron, although they arise initially from the collecting ducts.
  - One kidney may be larger than the other.
- **ARPKD**
  - Disease is a spectrum, ranging from severe renal disease with mild liver damage to mild renal disease with severe liver damage.
  - Renal enlargement is due to fusiform dilatation of the collecting ducts in the cortex and medulla in the newborn period.
  - Liver lesion is diffuse but limited to fibrotic portal areas.

### TREATMENT

#### GENERAL MEASURES
- **HTN:** moderate sodium restriction, weight control, and regular exercise
- **Medications:** ACE inhibitors; angiotensin receptor blockers (ARBs)
- **Pain:** narcotics and other analgesics; bed rest; limit NSAIDs (they worsen renal function).
* Urolithiasis: treated with alkalinization of urine and hydration therapy; surgery as needed
* UTIs/infections of cysts: lipid-soluble antibiotics more effective (e.g., trimethoprim-sulfamethoxazole and chloramphenicol); fluoroquinolones also useful
* Dialysis for ESKD patients
* Hematuria: Reduce physical activity.

**MEDICATION**
* No specific drug therapy is yet available for PKD, although several studies are being conducted for specific treatments (2)[C],(5)[C],(6).
* HTN: should be very well controlled to prevent complications. ACE inhibitors are preferred if no contraindications are present.
* The use of antihypertensive medications has been found to decrease mortality (7)[B].
* Hyperlipidemia: statins preferred

**ISSUES FOR REFERRAL**
* Nephrologist primary management
* Urologic consultation for management of symptomatic/infected cysts
* Genetic counseling is critical.

**SURGERY/OTHER PROCEDURES**
* Indications for surgical intervention
  - Uncontrollable HTN
  - Severe back and loin pain, abdominal fullness
  - Renal deterioration due to enlarging cysts
  - Hematuria/hemorrhage or recurrent UTI
* Open and laparoscopic cyst unroofing: may decrease pain and narcotics requirements; has not been proven to prevent renal failure or to prolong current renal function
* Percutaneous cyst aspiration ± injection of sclerosing agent; not usually performed secondary to recurrent fluid accumulation
* Renal transplant for ESKD

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Severe pain, gross hematuria with clots

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
None in early stages of the disease; avoid vigorous activity if disease advances. Recurrent gross hematuria is secondary to trauma, associated with faster decline of renal function.

**Patient Monitoring**
* Monitor blood pressure and renal function. Encourage hydration. Treat UTI and stone disease aggressively.
* Avoid nephrotoxic drugs.
* Creatinine and BP monitoring at least twice a year; more often as needed
* Screening for intracranial aneurysms (8)
DIET
- Low-protein diet may retard renal insufficiency.
- Limit caffeine because this might increase cyst growth.
- High water intake to decrease ADH >3 L/day (5)[C]

PROGNOSIS
- Renal failure in 2% by age 40 years; 23% by age 50 years; 48% by age 73 years
- ADPKD accounts for 10–15% of dialysis patients.
- No increased incidence of renal cell cancer

COMPLICATIONS
- Cyst rupture, infection, or hemorrhage
- Progression to renal failure
- Renal calculi

REFERENCES

ADDITIONAL READING
Chronic Kidney Disease

CODES

ICD10
- Q61.3 Polycystic kidney, unspecified
- Q61.19 Other polycystic kidney, infantile type
- Q61.2 Polycystic kidney, adult type

CLINICAL PEARLS

- Most PKD patients eventually develop ESKD. No specific treatment has been proven to prevent EKRD, but hydration and control of BP are reasonable goals and should be started soon.
- Patients may benefit from a nephrology consultation after the initial diagnosis to counsel regarding disease progression prevention. Then, they can be followed by primary care if the disease was an incidental finding or no significant kidney dysfunction is present.
**POLYCYSTIC OVARIAN SYNDROME (PCOS)**
Melissa Dennis, MD • Katherine Tadros, DO • Tiphany Jackson, MD

**BASICS**

**DESCRIPTION**
- Polycystic ovarian syndrome (PCOS) is a common endocrine disorder with heterogeneous manifestations that affects 6–10% of the U.S. population.
- Characterized by hyperandrogenism, insulin resistance, and anovulation, typically presenting as amenorrhea or oligomenorrhea.
- Diagnostic clinical characteristics include menstrual dysfunction, infertility, hirsutism, acne, obesity, and metabolic syndrome.
- The ovaries are often polycystic on imaging.
- The etiology of PCOS is unknown but presentation and course can be modified by lifestyle factors.
- System(s) affected: reproductive, endocrine/metabolic, skin/exocrine
- Synonym(s): Stein-Leventhal syndrome; polycystic ovary disease

**ALERT**
- Condition may begin at puberty.
- Obesity may amplify PCOS, but it is not diagnostic.
- 20% of women with PCOS are not obese.
- Predisposes to and is associated with obesity, hypertension, diabetes, metabolic syndrome, hyperlipidemia, infertility, insulin-resistance syndrome, endometrial hyperplasia, and uterine cancer

**EPIDEMIOLOGY**

**Prevalence**
- Incidence and prevalence are still highly debated due to a wide spectrum of diagnostic features: The National Institutes of Health (NIH) criteria require chronic anovulation and hyperandrogenism.
- The prevalence based on NIH criteria is 7% of reproductive age women.
- Predominant age: reproductive age
- Predominant sex: females only

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Recent evidence points to a primary role for insulin resistance with hyperinsulinemia.
- Increased GnRH pulsations in the hypothalamus lead to increased production of LH with limited production of FSH.
- Hyperandrogenism: Ovaries are the main source of excess androgens (75% of circulating testosterone originates in the ovary). Polycystic ovaries have thickened thecal layers and overexpressed LH receptors, which cause excess androgen secretion.
- Ovarian follicles: Abnormal androgen signaling may account for abnormal folliculogenesis causing polycystic ovaries.
- Obesity results in compensatory hyperinsulinemia: Women with PCOS have insulin resistance
similar to that in type 2 diabetes. Elevated levels of insulin decrease sex hormone–binding globulin (SHBG), increasing bioavailability of testosterone. Insulin may also act directly on adrenal glands, ovaries, and hypothalamus to enhance androgen production.

- Insulin resistance causes elevated insulin levels and the frequently associated metabolic syndrome or frank diabetes mellitus.

**Genetics**
- Likely a combination of polygenic and environmental factors
- Implicated genes include DENND1A and THADA.

**RISK FACTORS**
See “Commonly Associated Conditions”; cause and effect are difficult to extricate in this disorder.

**GENERAL PREVENTION**
None known; focus on early diagnosis and treatment to prevent long-term complications.

**COMMONLY ASSOCIATED CONDITIONS**
- Infertility
- Obesity
- Obstructive sleep apnea
- Hypertension
- Diabetes mellitus
- Endometrial hyperplasia/carcinoma
- Fatty liver disease
- Mood disturbances and depression
- Hirsutism

**DIAGNOSIS**

**HISTORY**
- A comprehensive history, including a family history of diabetes and premature onset of cardiovascular disease, is important in the differential diagnosis.
- Focus on the onset and duration of the various signs of androgen excess, menstrual history, and concomitant medications, including the use of exogenous androgens (1).
- Unpredictable, heavy, or absent menstrual cycles

**PHYSICAL EXAM**
- Vital signs: elevated body mass index (BMI), hypertension
- General appearance: central obesity, hirsutism, acne
- Skin: male hair pattern, balding, acne, seborrhea, acanthosis nigricans
- Pelvic: ovarian enlargement, clitoromegaly

**ALERT**
Look specifically for signs of virilization, such as hair pattern, deepened voice, and clitoromegaly because they indicate significant testosterone levels beyond that of PCOS.

**DIFFERENTIAL DIAGNOSIS**
Cushing syndrome
HAIR-AN syndrome
Androgen-secreting ovarian or adrenal tumor
Prolactin-producing pituitary adenoma
Hyperthecosis
Adult-onset adrenal hyperplasia
Partial congenital adrenal hyperplasia (21-hydroxylase deficiency)
11β-Hydroxylase deficiency
17β-Hydroxysteroid dehydrogenase deficiency
Acromegaly
Drug-induced hirsutism, oligo-ovulation (e.g., danazol, steroids, valproic acid)
Thyroid disease
Idiopathic hirsutism
Polycystic ovaries

**DIAGNOSTIC TESTS & INTERPRETATION**

The value of measurement of circulating androgens to document PCOS is uncertain but should include calculating free testosterone concentration using mass spectrometry of total testosterone and measurement of SHBG (2)[C].

Most commonly used diagnostic criteria is the Rotterdam criteria (need any 2 of 3):
- Oligomenorrhea or amenorrhea
- Clinical and/or biochemical signs of hyperandrogenism
- Transvaginal ultrasonographic polycystic ovaries

Must exclude other etiologies including Cushing disease, congenital adrenal hyperplasia, and androgen-secreting tumors

Ultrasoundographic polycystic ovaries are not necessary for the diagnosis of PCOS.

More recent criteria also focus on similar criteria while acknowledging that there may be forms of PCOS without overt evidence of hyperandrogenism (3)[C].

**Initial Tests (lab, imaging)**

Screening workup should rule out pregnancy, thyroid disease, hyperprolactinemia, and premature ovarian failure with human chorionic gonadotropin (hCG), TSH, prolactin, FSH, respectively.

Hirsute women should have a free testosterone determination (total testosterone minus SHBG) and a DHEA-S.

Consider 17-OH progesterone if congenital adrenal hyperplasia is suspected.

Typical findings in PCOS include testosterone increased but <200 ng/dL (6.94 nmol/L), mild elevation in DHEA-S but <800 μg/dL (20.8 μmol/L), mild increase in 17-OH progesterone level, increased estrogen level, and decreased SHBG.

More elevated levels of testosterone or DHEA-S may be associated with an androgen-secreting tumor of the ovaries or adrenal glands.

Anovulation can be determined by a midluteal phase progesterone level (>3 ng/mL if the woman has ovulated).

LH/FSH level ≥2.5 to 3.0 in ~50% of women with PCOS, but such testing is not generally necessary

Drugs that may alter lab results:
- Oral contraceptive pills (OCPs)
- Steroids
- Antidepressants

Transvaginal ultrasound findings: one or both ovaries with $\geq 12$ follicles measuring 2 to 9 mm or increased ovarian volume to 10 cm$^3$

**Follow-Up Tests & Special Considerations**
- Consider fasting serum glucose, insulin level, and plasminogen activator inhibitor-1 determinations to establish presence of insulin resistance and glucose intolerance, especially if diagnosis is in doubt.
- Overnight dexamethasone suppression test to rule out Cushing syndrome in the appropriate setting
- Endometrial biopsy to rule out hyperplasia and/or carcinoma, if indicated
- If the syndrome is diagnosed, determination of fasting glucose and fasting lipid levels should be performed and formal glucose tolerance test is considered.

**ALERT**
Prolonged or heavy bleeding should prompt an endometrial biopsy for evaluation of endometrial hyperplasia and possible cancer.

**Test Interpretation**
- Ovary is usually enlarged with a smooth white glistening capsule.
- Ovarian cortex is lined with follicles in all stages of development but most atretic.
- Thecal cell proliferation with an increase in the stromal compartment

**TREATMENT**

**GENERAL MEASURES**
Lifestyle changes including appropriate nutrition and exercise to decrease body weight by as little as 5% can restore ovulation and increase insulin sensitivity (4)[A]. Treatment plan should be individualized based on patient needs and desires.

**MEDICATION**
- The goal of treatment in PCOS depends on symptoms and patient’s goals for fertility.
- Treatment can be divided into four main categories: (i) restore menses, (ii) decrease insulin resistance, (iii) ameliorate androgen excess, and (iv) assist in fertility.

**First Line**
- Restore menses when pregnancy not desired:
  - OCPs and progestins provide improvement in menstrual irregularity and provide endometrial protection.
  - Low-dose OCPs (30 to 35 $\mu$g); newer formulations containing progestins with lower androgenicity (e.g., norethindrone, desogestrel, norgestimate, drospirenone) may be particularly beneficial, but all OCPs increase SHBG and decrease excess androgens.
  - Levonorgestrel IUD offers endometrial protection and pregnancy prevention but will not counteract hyperandrogenism (2).
  - If unable to tolerate OCPs, then intermittent medroxyprogesterone (Provera) 10 mg PO, or micronized progesterone (Crinone and Prometrium) 200 mg PO, for 10 to 14 days can be
given every 1 to 3 months (2)[C]. These offer endometrial protection. However, these will not counteract hyperandrogenism nor protect against pregnancy.

- **Decrease insulin resistance:**
  - Metformin may help to correct metabolic abnormalities in women who are insulin resistant. Initial dose is 500 mg daily for 1 week, increasing by 500 mg/week to a total of 1,500 to 2,000 mg/day divided BID; take with food.
    - Overall, data support the usefulness of metformin on both cardiometabolic risk and reproduction assistance in PCOS women.
    - Thiazolidinediones may increase likelihood of ovulation and treat insulin resistance but do not increase live birth rate.

- **If pregnancy is desired:**
  - Previously, the first-line treatment for ovulation induction was clomiphene (Clomid, Serophene) and/or exogenous gonadotropins. Live birth rate with clomiphene (Clomid) is 10.1% (5).
  - More recent data shows that letrozole (an aromatase inhibitor) has increased ovulation rates, clinical pregnancy rates, and live birth rates compared to clomiphene (Clomid). Live birth rate with letrozole is 27.5%. Dosing starts on day 3, 4, or 5 with 2.5 mg daily for 5 days; can increase to 5 mg daily with max dose 7.5 mg daily for 5 days (5)
  - Counsel patients that letrozole is not approved by the FDA for ovulation induction.
  - Metformin: 500 to 2,000 mg PO divided BID has been shown to improve hyperandrogenism and restore ovulation. Some providers will choose to continue metformin throughout the 1st trimester or the entire pregnancy if there is a history of spontaneous abortion or glucose intolerance. It does improve ovulation rates and insulin resistance but does not improve live birth rates alone or in combination with clomiphene when used for ovulation induction (6)[B].
  - Metformin reduces the incidence of gestational diabetes.
  - All ovulation induction drugs increase the risk of multiple births and obstetric complications, such as preterm birth and hypertensive disorders.

**Second Line**

- **Acne:**
  - OCPs with low-androgenicity progestins (e.g., norethindrone, desogestrel, norgestimate, drospirenone)
  - Spironolactone: 50 to 200 mg daily in 1 to 2 divided doses for acne and hirsutism not addressed by OCP therapy. This medication is unsafe in pregnancy, and potassium levels must be followed closely when used.

- **Hirsutism:**
  - Eflornithine hydrochloride 13.9% cream BID
  - Finasteride 2.5 to 5.0 mg daily. Must be on very reliable contraception as this medication is teratogenic

**ISSUES FOR REFERRAL**

- To reproductive endocrinologist for all women who cannot achieve pregnancy with clomiphene (Clomid) or letrozole
- To endocrinologist if Cushing syndrome, congenital adrenal hyperplasia, or adrenal or ovarian tumors are found during the workup
ADDITIONAL THERAPIES
Mechanical means of hair removal, including laser, electrolysis, waxing, and depilatory, may improve cosmesis.

SURGERY/OTHER PROCEDURES
Ovarian wedge resection and laparoscopic laser drilling are controversial and rarely used today.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture may assist with cycle normalization and weight loss.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
6-month intervals to evaluate response to therapy and to monitor weight and medication side effects

Patient Monitoring
- Counsel patient about the risk of endometrial and breast carcinoma, insulin resistance, and diabetes as well as obesity and its role in infertility.
- See patient frequently throughout the menstrual cycle, depending on which drug combination is used to induce ovulation.
- All patients with PCOS who have not received medication or IUD for endometrial protection and have been amenorrheic for 1 year should undergo endometrial biopsy.

DIET
In overweight patients, weight loss is the most successful therapy because it improves cardiovascular risk, insulin sensitivity, menstrual patterns, and infertility. Counsel on lifestyle dietary changes; consider referral to nutritionist and weight center. No specific diet plan is proven to be better than another.

PATIENT EDUCATION
- Provide patient with information about PCOS, such as from http://www.acog.org/.
- Discuss the chronic nature of this condition and the risks and benefits and side effects of potential treatments.
- Review the importance of exercise and weight loss, if applicable. Modest weight loss of 5–10% of initial body weight has been demonstrated to improve many of the features of PCOS.

PROGNOSIS
- Fertility prognosis is good but may need assisted reproductive technologies.
- Proper follow-up and screening can prevent endometrial carcinoma.
- Early detection of diabetes may decrease morbidity and mortality associated with cardiovascular risk factor.

COMPLICATIONS
- Reproductive: infertility
- Metabolic: insulin resistance, diabetes mellitus, cardiovascular disease
- Psychosocial: increased anxiety, mood disorder, eating disorder, depression
- Predisposes to endometrial hyperplasia and as high as 9% lifetime risk of endometrial cancer
Women with PCOS appear to be at increased risk of complications of pregnancy including gestational diabetes and hypertensive disorders.

REFERENCES

SEE ALSO

Algorithm: Amenorrhea, Secondary

CODES

ICD10

- E28.2 Polycystic ovarian syndrome
- L68.0 Hirsutism

CLINICAL PEARLS

- Based on Rotterdam criteria, PCOS is diagnosed based on 2 of 3 of (i) oligo-ovulation, (ii) signs of hyperandrogenism, (iii) polycystic ovaries.
- Polycystic ovaries are not required for the diagnosis of PCOS.
- All patients with anovulation should be evaluated for pregnancy.
- Chronic anovulation should be treated because chronic estrogen stimulation in absence of progesterone may lead to endometrial hyperplasia.
- Specific therapies must be individualized according to the needs and desires of each patient.
- Letrozole is now the first-line medication for ovulation induction.
POLYCYTHEMIA VERA
Thuy Thanh Thi Le, DO ● Boris Calderon, DO

BASICS

DESCRIPTION
- Polycythemia vera (PV) is a myeloproliferative clonal stem cell disorder marked by increased production of red blood cells (erythrocytosis) with excessive erythroid, myeloid, and megakaryocytic elements in the bone marrow.
- Morbidity and mortality are primarily related to complications from blood hyperviscosity leading to thrombosis development as well as malignant transformation. Untreated patients may survive 6 to 18 months. Adequate treatment may extend life to >10 years.
- Myelofibrosis can develop in the bone marrow, leading to progressive hepatosplenomegaly.
- Synonyms: primary polycythemia; maladie de Vaquez disease; primary PV; PV rubra; polycythemia, splenomegalic; Vaquez-Osler disease

EPIDEMIOLOGY

Incidence
- Predominant age: 50 to 75 years; however, can occur in early adulthood and childhood
- Predominant sex: male > female (slightly)
- Incidence in the United States in 2012: 2.8/100,000 population of men and 1.3/100,000 population of women; highest for men 70 to 79 years at 23.5/100,000 persons per year

Prevalence
In the United States in 2010, estimates ranged from 45 to 57 cases per 100,000 patients.

ETIOLOGY AND PATHOPHYSIOLOGY

JAK2 V617F mutation associated with clonal proliferative disorder

Genetics
JAK2 V617F (tyrosine kinase) mutation: >97% of patients with PV have an activating mutation; this is helpful in differentiating from secondary erythrocytosis. Homozygote carriers will have higher incidence of symptoms such as pruritus but will not have higher incidence of disease than heterozygotes.

RISK FACTORS
- PV may be slightly more prevalent among Jews of Eastern European descent than other Europeans or Asians.
- Familial history is rare.

COMMONLY ASSOCIATED CONDITIONS
- Budd-Chiari syndrome
- Ischemic digits
- Mesenteric artery thrombosis
- Myocardial infarction
- Cerebrovascular accident or transient ischemic attack
- Venous thromboembolism and pulmonary embolism
DIAGNOSIS

HISTORY
- Patients may be asymptomatic or present with nonspecific complaints, including fatigue, malaise, weight loss, sweating, and subjective weakness.
- Erythromelalgia (burning pain of feet/hands, occasionally with erythema, pallor, cyanosis, or paresthesias)
- Pruritus, especially after bathing (aquagenic pruritus)
- Arterial and venous occlusive events
- Headaches
- Blurred vision or blind spots
- Tinnitus, vertigo, dizziness
- Spontaneous bruising/bleeding
- Peptic ulcer disease (due to alterations in gastric mucosal blood flow)
- Early satiety due to enlarged spleen
- Bone pain (ribs and sternum)
- Gout
- Insomnia
- Depressed mood

PHYSICAL EXAM
- Hypertension (46%)
- Splenomegaly (75%), palpable spleen (36%)
- Hepatomegaly (30%)
- Facial plethora (ruddy cyanosis)
- Bone tenderness (especially ribs and sternum)
- Skin excoriations from significant pruritus
- Gouty tophi or arthritis
- Injection of the conjunctival small vessels and/or engorgement of the veins of the optic fundus

DIFFERENTIAL DIAGNOSIS
- Secondary erythrocytosis:
  - Sleep apnea
  - Emphysema
  - Cigarette smoking
  - Renal artery stenosis
  - Carbon monoxide poisoning
  - Drugs: diuretics, testosterone, erythropoietin (EPO)
- Hemoglobinopathy
- Ectopic EPO production
- Spurious polycythemia

DIAGNOSTIC TESTS & INTERPRETATION
- CBC; if suspicion is high, then obtain EPO level and gene testing for JAK2 V617F.
- If the only indication of PV is elevated hemoglobin (Hgb)/Hct, a CBC should be repeated. Further testing is unnecessary if the Hgb/Hct return to normal.
Initial Tests (lab, imaging)

- 2016 World Health Organization diagnostic criteria require all three major criteria or the first 2 major criteria and the minor criterion*(1).
  - Major criteria:
    - Hgb >16.5 g/dL (men); Hgb >16.0 g/dL (women) or Hct >49% (men); Hct >48% (women) or increased cell mass (>25% above mean normal predictive value)
    - Bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) including prominent erythroid, granulocytic, and megakaryocytic proliferation with pleomorphic, mature megakaryocytes (difference in sizes)
    - Presence of JAK2 V617F or similar mutation such as JAK2 exon 12 mutation
  - Minor criteria:
    - Serum EPO level below normal *criterion number 2 (BM biopsy) may not be required in cases with substantive absolute erythrocytosis: Hgb >18.5 g/dL in men (Hct, 55.5%) or >16.5 g/dL in women (Hct, 49.5%) if major criterion 3 and minor criterion are present. However, initial myelofibrosis (present in up to 20% of points) can only be detected by performing a bone marrow biopsy; this finding may predict a more rapid progression to overt myelofibrosis (post-PV MF).

- Other lab findings that are common but not specific
  - Hyperuricemia
  - Hypercholesterolemia
  - Elevated serum vitamin B₁₂ levels
  - Prolonged PT, aPTT due to low plasma volume
  - Thrombocytosis (>400,000 platelets/mm³)
  - Leukocytosis (>12,000/mm³)
  - Leukocyte alkaline phosphatase (100,000 U in the absence of fever or infection)
- CT or US to assess for splenomegaly, although not necessary for diagnosis
- Arterial oxygen saturation (<92% SaO₂) and carboxyhemoglobin (COHb)
- Bone marrow biopsy is not necessary. There is no staging system for this disease.

Diagnostic Procedures/Other

- Bone marrow aspiration, if performed, shows hypercellularity of erythroid, granulocytic and megakaryocytic lines, or myelofibrosis.
- Cytogenetic testing (JAK2 V617F)

Test Interpretation

- If JAK2 V617F mutation testing is negative and the EPO level is normal or high, then PV is excluded; investigate causes of secondary erythrocytosis.
- Other causes of erythrocytosis such as ectopic EPO production from a renal tumor, hypoxia from chronic lung, or cyanotic heart disease can be excluded with low or undetectable serum EPO level and normal oxygen saturation.

TREATMENT

GENERAL MEASURES

- Risk factors: Patients >60 years with history of thrombosis are high risk. Those who are <60
years with no history of thrombosis but with elevated platelets (>150,000) are intermediate risk. <60 years, with normal platelets, and no history of thrombosis are low risk.

- Phlebotomy and low-dose aspirin is first-line therapy for all patients.
- Although not curative, modern therapy for PV can relieve symptoms and prolong survival.
- If secondary PV, address etiology: aggressive treatment of obstructive sleep apnea, COPD (esp. smoking cessation), renal disease; consider lowering dose in testosterone replacement.
- Phlebotomy reduces the blood hyperviscosity, improves platelet function, restores systemic pressures, and decreases risk of thrombosis.
- Phlebotomy:
  - Reduce hematocrit to <45%; will significantly lower rate of cardiovascular death and major thrombosis \(^{(2)}\)[A]
  - Performed initially as often as every 2 to 3 days until normal hematocrit reached; phlebotomies of 250 to 500 mL (1 unit—500 mL—phlebotomy should reduce hematocrit by 3 percentage points) Reduce to 250 to 350 mL in elderly patients or patients with cerebrovascular disease.
  - Frail patients should have volume replaced with saline solution to avoid postural hypotension.
  - High risk for thrombosis or presence of elevated platelet count is indication for cyto-reductive therapy.
  - Complications of phlebotomy: chronic iron deficiency (symptomatology: pica, angular stomatitis, and glossitis), possible muscle weakness, and dysphagia that is the result of esophageal webs (very rare).

- Other therapies:
  - Maintain hydration.
  - Pruritus therapy: H\(_1\) and H\(_2\) blockers, SSRIs, oatmeal baths, interferon \(\alpha\)-2b
  - Uric acid reduction therapy

**MEDICATION**

**First Line**

- Primary therapies:
  - Low-dose aspirin 81 mg PO has been associated with a statistically nonsignificant reduction in the risk of fatal thrombotic events without increasing bleeding complications when used in conjunction with phlebotomy \(^{(3)}\)[A]. Aspirin should not be used in those with acquired von Willebrand disease or those with other contraindications.
  - Hydroxyurea is recommended for patients at high risk for thrombosis (age >60 years or history of thrombotic event) and with splenomegaly and hepatomegaly. Common starting dose 500 to 1,500 mg PO daily, titrating to control hematocrit and platelet count. Be aware that hydroxyurea can lead to skin ulcer, myelosuppression, and higher risk of leukemic transformation \(^{(4)}\)[A].
  - Ruxolitinib is approved for refractory PV or for patients who are intolerant to hydroxyurea.
  - Radioactive phosphorus \(^{(32}P)\) may control Hgb level and platelet count by destroying overactive marrow cells. May take up to 3 months before affecting cells. Consider for patients intolerant or nonadherent to hydroxyurea or short expected survival due to mutagenic potential.
  - Pegylated interferon \(\alpha\)-2a is effective in controlling erythrocytosis, although dosing is generally limited secondary to intolerable side effects; usually recommended for younger
patients (<40 years old) and those who might become pregnant
– Refer to hematologist/oncologist for further dosing and instructions.

Symptomatic/adjunctive:
– Allopurinol 300 mg/day PO for uric acid reduction
– Cyprihopectadine 4 to 16 mg PO daily as needed for pruritus
– H₂ receptor blockers or antacids for GI hyperacidity; cimetidine is also used for pruritus.
– Low-dose aspirin also used for pruritus/erythromelalgia
– SSRI s (paroxetine or fluoxetine) have shown some efficacy in controlling pruritus.
– Ultraviolet light may help with pruritus.

Second Line
Myelosuppression: chlorambucil or busulfan; busulfan at 2 to 4 mg daily may be effective option for elderly patients with advanced PV refractory or intolerant to other agents such as hydroxyurea and interferon, but significant rate of transformation was observed.

ISSUES FOR REFERRAL
Referral to a hematologist to assist in diagnosis and management

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Monitor hematocrit often and phlebotomize as needed to maintain target goal.

DIET
• Avoid high-sodium diet; can cause fluid retention
• Avoid iron supplement; a permissive chronic state of iron deficiency can help decrease blood production.

PATIENT EDUCATION
• Perform leg and ankle exercises to prevent clots.
• Continuous education regarding possible complications and seeking treatment early for any change or increase in symptoms

PROGNOSIS
• PV cannot be cured but can be controlled with treatment.
• Survival is >15 years with treatment.
• Patients are at risk for developing postpolycythemic myelofibrosis (PPMF) and an increased risk of malignant transformation.

COMPLICATIONS
• Splenomegaly or hepatomegaly
• Budd-Chiari syndrome
• Vascular thrombosis (major cause of death) (20%)
• Transformation to acute leukemia (5%)
• Transformation to myelofibrosis (10%)
• Hemorrhage
- Peptic ulcer
- Uric acid stones
- Secondary gout
- Increased risk for complications and mortality from surgical procedures. Assess risk/benefits and ensure optimal control of disorder before any elective surgery.

REFERENCES

ADDITIONAL READING

SEE ALSO

Myeloproliferative Neoplasms

CODES

ICD10
- D45 Polycythemia vera

CLINICAL PEARLS

- Erythrocytosis: Hgb >16.5 g/dL in men, >16.0 g/dL in women
- JAK2 mutations are an important component of myeloproliferative disorders.
- Bone marrow biopsy can help in diagnosis showing hypercellularity and trilineage growth.
- Common complications include thrombosis, malignant transformation, and myelofibrosis.
- All patients should take low-dose aspirin unless there is major bleeding or GI intolerance.
- Phlebotomy is first-line treatment, and consultation with an experienced hematologist is recommended.
POLYMYALGIA RHEUMATICA
Juliana Chang, MD

BASICS

DESCRIPTION
- A clinical syndrome characterized by pain and stiffness of the shoulder, hip girdles, and neck; primarily impacts the elderly, associated with morning stiffness and elevated markers of inflammation
- System(s) affected: musculoskeletal; hematologic/lymphatic/immunologic
- Synonym(s): senile rheumatic disease; polymyalgia rheumatica (PMR) syndrome; pseudo-polyarthritis rhizomélite

Geriatric Considerations
- Incidence increases with age.
- Average age of onset ~70 years

Pediatric Considerations
Rare in patients <50 years of age. The peak incidence of PMR is between ages 70 and 80 years (1).

EPIDEMIOLOGY

Incidence
- Incidence increases after age 50 years. Incidence of PMR and giant cell arteritis (GCA) in the United States is 50 and 18 per 100,000 people, respectively.
- Predominant sex: female > male (2 to 3:1)
- Most common in Caucasians, especially those of northern European ancestry
- Peak incidence occurs between age 70 and 80

Prevalence
Prevalence in those >50 years old: 700/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Unknown. Symptoms relate to enhanced immune system and periarticular inflammatory activity.
- Pathogenesis
  - Polygenic; involves multiple environmental and genetic factors
  - Significant association between histologic evidence of GCA and parvovirus B19 DNA in temporal artery specimen

Genetics
Associated with human leukocyte antigen determinants (HLA-DRB1*04 and DRB1*01 alleles)

RISK FACTORS
- Age >50 years
- Presence of GCA
COMMONLY ASSOCIATED CONDITIONS
Concurrent GCA (temporal arteritis) in ~15–30% of patients; more commonly in females than males

DIAGNOSIS

HISTORY
- Suspect PMR in elderly patients with new onset of proximal limb pain and stiffness (neck, shoulder, hip). Patients may use the term stiffness and pain interchangeably (2).
- Difficulty rising from chair or combing hair (proximal muscle involvement)
- Nighttime pain
- Can be unilateral; however, soon becomes symmetrical
- Severe morning stiffness
- Systemic symptoms in ~25% (fatigue, weight loss, low-grade fever)

PHYSICAL EXAM
- Decreased range of motion (ROM) of shoulders, neck, and hips
- Muscle strength is usually normal—may be limited by pain and/or stiffness.
- Muscle tenderness
- Disuse atrophy
- Synovitis of the small joints and tenosynovitis
- Coexisting carpal tunnel syndrome

DIFFERENTIAL DIAGNOSIS
- Rheumatoid arthritis (RA)
- Palindromic rheumatism
- Late-onset seronegative spondyloarthropathies (e.g., psoriatic arthritis, ankylosing spondylitis)
- Systemic lupus erythematosus; Sjögren syndrome; fibromyalgia
- Polymyositis-dermatomyositis (Check creatine phosphokinase, aldolase.)
- Thyroid disease
- Hyperparathyroidism, hypoparathyroidism
- Hypovitaminosis D
- Osteoarthritis
- Rotator cuff syndrome; adhesive capsulitis
- RS3PE syndrome (remitting seronegative symmetrical synovitis with pitting edema)
- Occult infection or malignancy (e.g., lymphoma, leukemia, myeloma, solid tumor)
- Myopathy (e.g., steroid, alcohol, electrolyte depletion)
- Depression

DIAGNOSTIC TESTS & INTERPRETATION
- Consider PMR in patients >50 years of age with proximal pain and stiffness—obtain labs and consider a diagnostic/therapeutic trial of low-dose steroids.
- Temporal artery biopsy if symptoms of GCA present
- ESR (Westergren) elevation >40 mm/hr
  - ESR generally elevated, sometimes >100 mm/hr
  - ESR normal (<40 mm/hr) in 7–22% of patients
- Elevated C-reactive protein
- Normochromic/normocytic anemia
- Anti-cyclic citrullinated peptide (anti-CCP) antibodies usually negative (in contrast to elderly-onset RA)
- Rheumatoid factor (RF): negative (5–10% of patients >60 years have positive RF without RA.)
- Mild elevations in liver function tests, especially alkaline phosphatase
- Antibodies to ferritin peptide may be a useful diagnostic marker.
- Prednisone may alter lab results.
- Other disorders may cause elevation of ESR (e.g., infection, neoplasm, renal failure).
- Normal EMG
- Normal muscle histology
- CK is always normal

**Initial Tests (lab, imaging)**
- ESR (usually >40 mm/hr)
- C-reactive protein
- CBC
- MRI is not necessary for diagnosis but may show periarticular inflammation, tenosynovitis, and bursitis.
- US may show bursitis, tendinitis, and synovitis.
- MRI, PET, and temporal artery US may help in diagnosis of PMR.
- ACR/EULAR classification criteria help confirm the clinical diagnosis (3).
- 18F-fluorodeoxyglucose PET scan prior to therapy improves diagnostic accuracy (4).
- A scoring algorithm (3) was devised consisting of the following: morning stiffness >45 minutes (2 points), hip pain/limited ROM (1 point), absence of RF and anti-citrullinated protein antibody (ACPA) (2 points), and absence of peripheral joint pain (1 point).
- A score of >4 has 68% sensitivity and 78% specificity for PMR.

**Diagnostic Procedures/Other**
Temporal artery biopsy in patients with symptoms suggestive of GCA. Treat empirically pending results.

**TREATMENT**

**GENERAL MEASURES**
- Address risk of steroid-induced osteoporosis.
  - Obtain dual energy x-ray absorptiometry and check 25-OH vitamin D levels if necessary.
  - Consider antiresorptive therapies (bisphosphonates) for treatment of corticosteroid-induced osteoporosis.
- Encourage adequate calcium (1,500 mg/day) and vitamin D (800 to 1,000 U/day) supplementation.
- Physical therapy for ROM exercises, if needed

**MEDICATION**

**First Line**
- Prednisone: 10 to 20 mg/day PO initially; expect a dramatic (diagnostic) response within days.
15 mg/day is effective in almost all patients.
– May increase to 20 mg/day if no immediate response
– If no response to 10 to 20 mg/day within a week, reconsider diagnosis.

- Divided-dose steroids (BID or TID) may be useful initially (especially if symptoms recur in the afternoon).
- Consider using delayed-release prednisone taken at bedtime, which may help treat morning stiffness compared to immediate-release prednisone.
- Begin slow taper by 2.5 mg decrements every 2 to 4 weeks to a dose of 7.5 to 10.0 mg/day. Below this dose, taper by 1 mg/month to prevent relapse.
- Increase prednisone for symptom relapse (common).
- Corticosteroid treatment often lasts several years.
- May stop after 6 to 12 months if symptom free and ESR is normal

- Contraindications
  – Use steroids with caution in patients with chronic heart failure, diabetes mellitus (or other immunocompromised state), and systemic fungal or bacterial infection.
  – Treat any concurrent infections.

- Precautions
  – Long-term steroid use (>2 years) is associated with sodium and water retention, exacerbation of chronic heart failure, hypokalemia, increased susceptibility to infection, osteoporosis, fractures, hypertension, cataracts, glaucoma, avascular necrosis, depression, and weight gain.
  – Patients may develop temporal arteritis while on low-dose corticosteroid treatment for PMR. This requires an increase in prednisone dosing (up to 40–60 mg).
  – Alternate-day steroids are not effective.

**Second Line**

- NSAIDs usually are not adequate for pain relief.
- Methotrexate modestly reduces relapse rate and lowers the cumulative dose of steroid therapy but has not been formally studied in PMR.
- There is conflicting evidence for anti-tumor necrosis factor (anti-TNF) agents (infliximab, etanercept).
- Anti–interleukin-6 (anti–IL-6) therapy under study (5,6)
- Corticosteroid injections (primarily for the shoulder) may help reduce pain and duration of morning stiffness, allowing for increased levels of activity.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Monthly evaluations initially and during medication taper; every 3 months otherwise
- Follow ESR as steroids are tapered; ESR and C-reactive protein should decline as symptoms improve.
- Follow up immediately for symptoms of GCA (e.g., headache, visual loss, and diplopia).
- Monitor side effects of corticosteroid therapy (osteoporosis, hypertension, and hyperglycemia).
- If patient is asymptomatic, do not treat elevated ESR (do not increase steroid dose to normalize
ESR).

**DIET**
- Regular diet
- Adequate calcium and vitamin D

**PATIENT EDUCATION**
- Review adverse effects of corticosteroids.
- Discuss the symptoms of GCA (headache, visual loss, diplopia) and present immediately if any occur.
- Follow up if symptoms recur during steroid taper.
- Do not abruptly stop steroids.
- Ensure adequate calcium and vitamin D intake.
- Patient resources:
  - Arthritis Foundation: [www.arthritis.org/](http://www.arthritis.org/)
  - American College of Rheumatology: [http://www.rheumatology.org/Practice/Clinical/Patients/Diseases_And_Conditions/Polymyalgia_Rheumatica/](http://www.rheumatology.org/Practice/Clinical/Patients/Diseases_And_Conditions/Polymyalgia_Rheumatica/)

**PROGNOSIS**
- Most patients require at least 2 years of corticosteroid treatment.
- Exacerbation or relapse is common if steroids are tapered too quickly.
- Prognosis is very good with proper treatment.
- Relapse is common (in 25–50% of patients).
- Higher age at diagnosis, female sex, high baseline ESR, increased levels of soluble IL-6 receptor, and high initial steroid dose have been associated with a prolonged disease course and more disease flares.

**COMPLICATIONS**
- Complications related to chronic steroid use
- Exacerbation of disease with taper of steroids; development of GCA (may occur when PMR is being treated adequately)

**REFERENCES**
ADDITIONAL READING

SEE ALSO
Arteritis, Temporal; Arthritis, Rheumatoid (RA); Depression; Fibromyalgia; Osteoarthritis; Polymyositis/Dermatomyositis

CODES

ICD10

- M35.3 Polymyalgia rheumatica
- M31.5 Giant cell arteritis with polymyalgia rheumatica

CLINICAL PEARLS

- Consider PMR in patients >50 years who present with hip, neck, and/or shoulder pain and stiffness.
- A normal ESR does not exclude PMR.
- Corticosteroids are the treatment of choice. If there is not a dramatic and rapid response, reconsider the diagnosis.
- Adjust steroids according to symptoms, not ESR.
BASICS

DESCRIPTION

● Systemic connective tissue disease characterized by inflammatory and degenerative changes in proximal muscles, sometimes accompanied by characteristic skin rash
  – If skin manifestations (Gottron sign [symmetric, scaly, violaceous, erythematous eruption over the extensor surfaces of the metacarpophalangeal and interphalangeal joints of the fingers]; heliotrope [reddish violaceous eruption on the upper eyelids]) are present, it is designated as dermatomyositis.
  – Different types of myositis include the following (1):
    o Idiopathic polymyositis
    o Idiopathic dermatomyositis
    o Polymyositis/dermatomyositis as an overlap (usually with lupus or systemic sclerosis or as part of mixed connective-tissue disease)
    o Myositis associated with malignancy
    o Necrotizing autoimmune myositis (often statin associated) (2)
    o Inclusion body myositis (IBM), a variant with atypical patterns of weakness and biopsy findings
● System(s) affected: cardiovascular, musculoskeletal, pulmonary, skin/exocrine
● Synonym(s): myositis; inflammatory myopathy; antisynthetase syndrome (subset with certain antibodies)

EPIDEMIOLOGY

Incidence

● Estimated at 1.2 to 19 per million population per year
● Predominant age: 5 to 15 years, 40 to 60 years, peak incidence in mid-40s
● Predominant sex: female > male (2:1)

Prevalence

2.4 to 33.8 patients per 100,000 population

Geriatric Considerations

Elderly patients with myositis or dermatomyositis are at increased risk of neoplasm.

Pediatric Considerations

Childhood dermatomyositis is likely a separate entity associated with cutaneous vasculitis and muscle calcifications.

ETIOLOGY AND PATHOPHYSIOLOGY

● Inflammatory process, mediated by T cells and cytokine release, leading to damage to muscle cells (predominantly skeletal muscles)
● In patients with IBM, degenerative mechanisms may be important.
● Unknown; potential viral, genetic factors
Genetics
Mild association with human leukocyte antigen (HLA)-DR3, HLA-DRw52

RISK FACTORS
Family history of autoimmune disease (e.g., systemic lupus, myositis) or vasculitis

COMMONLY ASSOCIATED CONDITIONS
- Malignancy more common in dermatomyositis
- Progressive systemic sclerosis
- Vasculitis
- Systemic lupus erythematosus (SLE)
- Mixed connective tissue disease

DIAGNOSIS

HISTORY
- Symmetric proximal muscle weakness causing difficulty when
  - Arising from sitting or lying positions
  - Climbing stairs
  - Raising arms
- Joint pain/swelling
- Dysphagia
- Dyspnea
- Rash on face, eyelids, hands, arms

PHYSICAL EXAM
Proximal muscle weakness
- Shoulder muscles
- Hip girdle muscles (trouble standing from seated or squatting position, weak hip flexors in supine position)
- Muscle swelling, stiffness, induration
- Distal muscle weakness is seen only in patients with IBM.
- Rash over face (eyelids, nasolabial folds), upper chest, dorsal hands (especially knuckle pads), fingers (“mechanic’s hands”)
- Periorbital edema
- Calcinosis cutis (childhood cases)
- Mesenteric arterial insufficiency/infarction (childhood cases)
- Cardiac impairment; arrhythmia, failure

DIFFERENTIAL DIAGNOSIS
- Vasculitis
- Progressive systemic sclerosis
- SLE
- Rheumatoid arthritis
- Muscular dystrophy
- Lambert-Eaton syndrome
- Sarcoidosis
Amyotrophic lateral sclerosis  
Endocrine disorders  
  – Thyroid disease  
  – Cushing syndrome  
Infectious myositis (viral, bacterial, parasitic)  
Drug-induced myopathies:  
  – Cholesterol-lowering agents (statins)  
  – Colchicine  
  – Corticosteroids  
  – Ethanol  
  – Chloroquine  
  – Zidovudine  
Electrolyte disorders (magnesium, calcium, potassium)  
Heritable metabolic myopathies  
Sleep apnea syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

Diagnosis of muscle component (myositis) usually relies on four findings:
  – Weakness  
  – Creatine kinase (CK) and/or aldolase elevation  
  – Abnormal electromyogram (EMG)  
  – Findings on muscle biopsy  
Presence of compatible skin rash of dermatomyositis

**Initial Tests (lab, imaging)**

- Increased CK, aldolase  
- Increased serum aspartate aminotransferase (AST)  
- Increased lactate dehydrogenase (LDH)  
- Myoglobinuria  
- Increased ESR  
- Positive rheumatoid factor (<50% of patients)  
- Positive antinuclear antibody (ANA) (>50% of patients)  
- Leukocytosis (<50% of patients)  
- Anemia (<50% of patients)  
- Hyperglobulinemia (<50% of patients)  
- Anti-HMGCR (3-hydroxy-3-methylglutaryl-coenzyme A reductase) and anti-SRP antibodies seen in patient with necrotizing autoimmune myositis  
- Antisynthetase antibodies (anti–Jo-1 and non–Jo-1 synthetases) present in antisynthetase syndrome  
  – Associated with an increased incidence of interstitial lung disease (ILD)  
- Anti–MDA-5 antibody seen in overlap myositis with atypical rashes and severe ILD  
- Anti–U1 RNP, anti–PM-Scl, and anti-Ku antibodies seen in overlap myositis  
- Chest radiograph as part of initial evaluation to assess for associated pulmonary involvement or malignancy

**Follow-Up Tests & Special Considerations**

- Changes in muscle enzymes (CK or aldolase) correlate with improvement and worsening.
MRI to assess muscle edema and inflammation may be used in some patients to determine best biopsy site or response to therapy.

**Diagnostic Procedures/Other**
- EMG: muscle irritability, low-amplitude potentials, polyphasic action potentials, fibrillations
- Muscle biopsy (deltoid or quadriceps femoris)

**Test Interpretation**
- Microscopic findings:
  - Muscle fiber degeneration
  - Phagocytosis of muscle debris
  - Perifascicular muscle fiber atrophy
  - Inflammatory cell infiltrates in adult form
  - Via electron microscopy: inclusion bodies (IBM only)
  - Sarcoplasmic basophilia
- Muscle fiber increased in size
- Vasculopathy (childhood polymyositis/dermatomyositis)

**TREATMENT**

**GENERAL MEASURES**
General evaluation for malignancy in all adults, particularly with dermatomyositis, at initial evaluation and during follow-up

**MEDICATION**

**First Line**
- Prednisone
  - 40 to 80 mg/day PO in divided doses
  - Consolidate doses and reduce prednisone slowly when enzyme levels are normal.
  - Probably need to continue 5 to 10 mg/day for maintenance in most patients
- For steroid-refractory or steroid-dependent patients: azathioprine 1 mg/kg PO (arthritis dose) once daily or BID
  - Methotrexate 10 to 25 mg PO weekly, useful in most steroid-resistant patients
- Rash of dermatomyositis may require topical steroids or oral hydroxychloroquine.
- Patients with IBM have very poor response to steroids and other first- and second-line drugs in general.

**Second Line**
- Other immunosuppressant drugs (e.g., cyclophosphamide, chlorambucil, cyclosporine, mycophenolate, tacrolimus) can be added to steroids.
- Combination methotrexate and azathioprine also may be useful in refractory cases.
- IVIG (3)[B] and rituximab (4)[B] have been reported to be helpful in a small series of patients with refractory disease. Rituanson may be more effective in patients with autoantibodies positive myositis (especially anti–Jo-1 and anti–Mi-2).
- Contraindications: Methotrexate is contraindicated with previous liver disease, alcohol use, pregnancy, and underlying renal disease (use with extreme caution in patients with serum creatinine >1.5 mg/dL in general).
Precautions
- Prednisone: Adverse effects associated with long-term steroid use include adrenal suppression, sodium and water retention, hypokalemia, osteoporosis, cataracts, and increased susceptibility to infection.
- Azathioprine: Adverse effects include bone marrow suppression, increased liver function tests, and increased risk of infection.
- Methotrexate: Adverse effects include stomatitis, bone marrow suppression, pneumonitis, and risk of liver fibrosis and cirrhosis with prolonged use.

ISSUES FOR REFERRAL
- Diagnostic uncertainty, usually related to elevated muscle enzymes without typical symptoms of findings of muscle weakness
- Poor response to initial steroid therapy
- Excessive steroid requirement (unable to taper prednisone to <20 mg/day after 4 to 6 months)

SURGERY/OTHER PROCEDURES
None indicated, other than initial biopsy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inability to stand, ambulate
- Respiratory difficulty
- Fever or other signs of infection
- Inpatient evaluation seldom needed

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow muscle enzymes along with muscle strength and functional capacity.
- Monitor for steroid-induced complications (e.g., hypokalemia, hypertension, and hyperglycemia).
- Bone densitometry and consideration of calcium, vitamin D, and bisphosphonate therapy
- If azathioprine, methotrexate, or other immunosuppressant is used, appropriate laboratory monitoring should be done periodically (e.g., hematology, liver enzymes, and creatinine).
- Attempt to decrease and/or discontinue steroid dose as patient responds to therapy.
- Maintain immunosuppression until patient’s muscle strength stabilizes for prolonged period depending on individual patient parameters, risks of medication, risk of relapse; time period undefined (months, years)

DIET
Moderation of caloric and sodium intake to avoid weight gain from corticosteroid therapy

PATIENT EDUCATION
- Curtail excess physical activity in early phases when muscle enzymes are markedly elevated.
- Emphasize range of motion exercises.
- Gradually introduce muscle strengthening when muscle enzymes are normal or improved and stable.
PROGNOSIS
- Residual weakness: 30%
- Persistent active disease: 20%
- 5-year survival 65–75%, but mortality is 3- to 5-fold higher than general population. Most of the increase in mortality occurs in the 1st year after diagnosis (5).
- Survival is worse for women and African Americans and those with dermatomyositis, IBM, or cancer.
- Most patients improve with therapy.
- Patient with ILD have poor prognosis.
- Patients with IBM respond poorly to most therapies (6).
- 20–50% have full recovery.

COMPLICATIONS
- Pneumonia
- Infection
- Myocardial infarction
- Carcinoma (especially breast, lung)
- Severe dysphagia
- Respiratory impairment due to muscle weakness, ILD
- Aspiration pneumonitis
- Steroid myopathy
- Steroid-induced diabetes, hypertension, hypokalemia, osteoporosis

REFERENCES

CODES

ICD10
- M33.20 Polymyositis, organ involvement unspecified
- M33.90 Dermatopolymyositis, unspecified, organ involvement unspecified
- M33.92 Dermatopolymyositis, unspecified with myopathy
CLINICAL PEARLS

- Corticosteroids alone may be sufficient in patients who have rapid improvement in weakness and muscle enzymes. However, most patients require azathioprine, methotrexate, or other immunosuppressive medications.
- The risk of associated malignancy is higher in patients >50 years and in those with cutaneous manifestations.
- Elevated muscle enzymes (e.g., CK and aldolase) are seen frequently as transient phenomena in patients with febrile illness and injuries; may return to normal on repeat.
- In patients with persistently elevated muscle enzymes and symptoms and findings of muscle weakness, EMG followed by muscle biopsy should be the initial studies considered.
- Suspect IBM in older patients with very slow onset and progression of symptoms, poor response to steroids and immunosuppressive therapy, and atypical patterns (asymmetric, sometimes distal) of muscle weakness.
- Suspect autoimmune necrotizing myositis in patients who develop myopathy while taking lipid-lowering drugs (statins) but fail to improve or worsen after withdrawal of statin therapy.
POPLITEAL (BAKER) CYST
Shane L. Larson, MD  Christopher Morrow, PA-C

**BASICS**

**DESCRIPTION**
- A fluid-filled synovial sac arising in the popliteal fossa as a distention of (typically) the gastrocnemial-semimembranous bursa; not a true cyst
- Can be unilateral or bilateral
- Most frequent cystic mass around the knee
- Primary cysts are a distention of the bursa (arise independently without an intra-articular disorder).
- Secondary cysts occur if there is a communication between the bursa and knee joint, allowing articular fluid to fill the cyst.
- Associated with synovial inflammation

**EPIDEMIOLOGY**

**Incidence**
- Bimodal distribution
  - Children ages 4 to 7 years
  - Adults increasing with age
- Primary cysts usually seen in children <15 years
- Secondary cysts seen in adults

**Prevalence**
- Variable adult prevalence of 19–47% in symptomatic knees and 2–5% in asymptomatic knees
- In children: 6.3% in symptomatic knees; 2.4% in asymptomatic knees

**ETIOLOGY AND PATHOPHYSIOLOGY**

Associated intra-articular pathology includes
- Meniscal tears, mostly of the posterior horn
- Anterior cruciate ligament (ACL) insufficiency
- Degenerative articular cartilage lesions
- Rheumatoid arthritis (20%)
- Osteoarthritis (50%)
- Osteochondritis
- Gout (14%)
- Other potential factors
  - Infectious arthritis
  - Polyarthritis
  - Villonodular synovitis
  - Lymphoma
  - Sarcoidosis
  - Connective tissue diseases
- Extension or herniation of synovial membrane of the knee joint capsule or connection of normal bursa with the joint capsule
May result from increased intra-articular pressure
Commonly seen with knee effusions
Direct trauma to the bursa is likely the primary cause in children because of no communication between the bursa and the joint.
A valve-like mechanism allowing one-way passage of fluid from the joint to the bursal connection has been described.

**RISK FACTORS**
- Osteoarthritis of knee (most common)
- Rheumatoid arthritis
- Meniscal degeneration or tear
- Advancing age
- Ligamentous trauma
- Ligamentous insufficiency

**COMMONLY ASSOCIATED CONDITIONS**
Any condition causing knee joint effusion

**DIAGNOSIS**

**HISTORY**
- Painless mass arising in the popliteal fossa
- Most cysts are asymptomatic.
- Dull ache if cyst is large enough to impede joint motion—typically a restriction of flexion
- Painful if cyst ruptures
- Large cysts may cause entrapment neuropathy of the tibial nerve.
- Vascular compression, most commonly of the popliteal vein, may produce claudication or thrombophlebitis.
- Activity alters the cyst size.

**PHYSICAL EXAM**
- Examine in full extension and 90 degrees of flexion.
- Foucher sign: Mass increases with extension and disappears with flexion.
- Most commonly found in medial aspect of popliteal fossa lateral to the head of the gastrocnemius and medial to the neurovascular bundle
- Cyst is easiest to palpate when knee is slightly flexed and may occasionally be fluctuant or tender.
- Transillumination helps distinguish cyst from solid mass.
- Ruptured cysts are typically painful with associated swelling and bruising over the ipsilateral calf and ankle at the medial malleolus (crescent sign).
- Ruptured cysts also are associated with pseudothrombophlebitis, and rarely, compartment syndrome (1).

**DIFFERENTIAL DIAGNOSIS**
- Deep venous thrombosis
- Infection/abscess
- Ganglion cyst
Hematoma
Thrombophlebitis
Lipoma, liposarcoma
Fibroma, fibrosarcoma
Vascular tumor
Popliteal vein varices
Xanthoma
Aneurysm (rare)
Muscular herniation (rare, related to trauma)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC, ESR (if septic arthritis suspected)
- Ensure not a popliteal aneurysm prior to aspiration. Send aspirate for cell count and culture to determine if fluid is infectious, inflammatory, or mechanical.
- Ultrasound confirms presence and size; Doppler can differentiate Baker cysts from popliteal vessel aneurysms, DVT, or soft tissue tumors (2).
- MRI helps assess derangements of internal joint structures and to identify cyst leakage.

Follow-Up Tests & Special Considerations
- Consider observation over invasive testing in children.
- Radiographs may show soft tissue density posteriorly.
- Arthrography may demonstrate communication with joint capsule or rupture.
- CT arthrography is superior for visualizing cystic details and can help distinguish lipomas, aneurysms, and malignancies from cysts.

TREATMENT

GENERAL MEASURES
- No treatment if asymptomatic
- Treat any associated underlying conditions.
- Compressive wrap or sleeve for comfort

MEDICATION
If etiology is identified from cellular fluid examination, treat the underlying condition.

First Line
Analgesics and NSAIDs for symptomatic relief

ADDITIONAL THERAPIES
- Physical therapy improves knee ROM and strength, particularly with coexisting pathology.
- Temporary relief with needle aspiration; recurrence common
- Improvement in joint ROM, knee pain, swelling, accompanied reduction in bursa size after aspiration, and intra-articular/intracystic corticosteroid injection (3)[B]
- A combination of physical therapy and corticosteroid injection with or without aspiration leads to best improvements in pain, function, and reduction in cyst size (4)[A].
- Sclerotherapy injections of ethanol or dextrose/sodium morrhuate shown to have good results
in small studies (5)[B].

SURGERY/OTHER PROCEDURES
- Consider excision when symptoms persist despite treatment or no etiology is found.
- Surgery usually not required in children.
- Recurrence after standard surgery is common and is highest if chondral lesions are present.
- Arthroscopic surgery is highly successful if a valvular mechanism is identified, and intra-articular pathology is treated (6)[B].
- Excision via arthroscopy or open procedure often requires concomitant treatment of underlying pathology.

ONGOING CARE

PROGNOSIS
- Variable; many cysts remain asymptomatic.
- Some cysts resolve with treatment of underlying etiology (e.g., gout, rheumatoid arthritis).
- In children, most cysts resolve without treatment.

COMPLICATIONS
- Compartment syndrome in ruptured cyst
- Thrombophlebitis from compression of the popliteal vein
- Infection of popliteal cyst
- Hemorrhage into cyst if on anticoagulants

REFERENCES

ADDITIONAL READING
SEE ALSO
Algorithm: Knee Pain

CODES

ICD10
- M71.20 Synovial cyst of popliteal space [Baker], unspecified knee
- M71.21 Synovial cyst of popliteal space [Baker], right knee
- M71.22 Synovial cyst of popliteal space [Baker], left knee

CLINICAL PEARLS
- Baker cyst: A fluid-filled synovial sac arising in the popliteal fossa as a distention of (typically) the gastrocnemial-semimembranous bursa; not a true cyst; often secondary to meniscal tear, osteoarthritis, etc.
- Conservative treatment of Baker cysts is preferred in children, as most will spontaneously resolve.
- In adults, treatment of underlying cause may resolve Baker cysts.
- Pain, bruising, and swelling over the medial malleolus (crescent sign) suggest cyst rupture.
PORTAL HYPERTENSION
Walter M. Kim, MD, PhD ● Jyoti Ramakrishna, MD, MPH

BASICS

DESCRIPTION
- Increased portal venous pressure >5 mm Hg that occurs in association with splanchnic vasodilatation, portosystemic collateral formation, and hyperdynamic circulation
- Most commonly secondary to elevated hepatic venous pressure gradient (HVPG; the gradient between portal and central venous pressures)
- Course is generally progressive, with risk of complications including acute variceal bleeding, ascites, hepatic encephalopathy, and hepatorenal syndrome.

EPIDEMIOLOGY

Incidence
- Prevalence: <200,000 persons in the United States
- Predominant age: adult
- Predominant sex: male > female

ETIOLOGY AND PATHOPHYSIOLOGY

Causes generally classified as follows:
- Prehepatic (portal vein thrombosis or obstruction)
- Intrahepatic (most commonly cirrhosis)
- Posthepatic (hepatic vein thrombosis, Budd-Chiari syndrome, right-sided heart failure)
- 90% of intrahepatic cases are due to cirrhosis secondary to the following:
  - Virus (hepatitis B, hepatitis C, hepatitis D)
  - Alcoholism
  - Nonalcoholic fatty liver disease
  - Schistosomiasis
  - Wilson disease
  - Hemochromatosis
  - Primary biliary cirrhosis (PBC)
  - Sarcoidosis
- Increased HVPG results in venous collateral formation in the distal esophagus, proximal stomach, rectum, and umbilicus.
- Gastroesophageal variceal formation is found in 40% of patients with portal hypertension.
- Progression of portal hypertension results in splanchnic vasodilation and angiogenesis.

Genetics
No known genetic patterns except those associated with specific hepatic diseases that cause portal hypertension

RISK FACTORS
See “Etiology and Pathophysiology.”

Pediatric Considerations
In children, portal vein thrombosis is the most common extrahepatic cause; intrahepatic causes are more likely to be biliary atresia, viral hepatitis, and metabolic liver disease.

**DIAGNOSIS**

**HISTORY**
- Ascites; symptoms of heart failure including chest pain, shortness of breath, and/or edema
- Hematemesis
- Melena
- Oliguria
- Jaundice
- Weakness/fatigue
- History of chronic liver disease
- Alcoholic hepatitis
- Alcohol abuse

**PHYSICAL EXAM**
- Exam findings may be general or related to specific complications.
  - General
    - Pallor
    - Icterus
    - Digital clubbing
    - Palmar erythema
    - Splenomegaly
    - Caput medusa
    - Spider angiomata
    - Umbilical bruit
    - Hemorrhoids
    - Gynecomastia
    - Testicular atrophy
  - Gastroesophageal varices
    - Hypotension
    - Tachycardia
  - Ascites
    - Distended abdomen
    - Fluid wave
    - Shifting dullness with percussion
  - Hepatic encephalopathy
    - Confusion/coma
    - Asterixis
    - Hyperreflexia

**DIFFERENTIAL DIAGNOSIS**
- Usually related to specific presentations
  - Gastroesophageal varices with hemorrhage
    - Portal hypertensive gastropathy
– Hemorrhagic gastritis
– Peptic ulcer disease
– Mallory-Weiss tear

• Ascites
  – Spontaneous bacterial peritonitis (SBP)
  – Pancreatic ascites
  – Peritoneal carcinomatosis
  – Tuberculous peritonitis
  – Hepatic malignancy
  – Fluid overload from heart failure
  – Nephrotic syndrome

• Hepatic encephalopathy
  – Delirium tremens
  – Intracranial hemorrhage
  – Sedative abuse
  – Uremia

• Hepatorenal syndrome
  – Drug nephrotoxicity
  – Renal tubular necrosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

Direct calculation of HVPG (approximation of the gradient in pressure between portal vein and IVC) is the gold standard in diagnosing portal hypertension:

- **HVPG = wedged hepatic venous pressure (WHVP) – free hepatic venous pressure (FHVP)**
- **WHVP** is estimated by occlusion of the hepatic vein by a balloon catheter and measurement of the proximal static column of blood.
- **FHVP** is estimated by direct measurement of the patent hepatic vein, intra-abdominal inferior vena cava, or right atrium.
- Esophageal varices generally develop when HVPG >10 mm Hg in compensated cirrhosis and HVPG >16 mm Hg in decompensated cirrhosis.

- **Nonspecific changes associated with underlying disease:**
  – Hypersplenism: anemia (also may be due to malnutrition or bleeding), leukopenia, thrombocytopenia
  – Hepatic dysfunction
    - Hypoalbuminemia
    - Hyperbilirubinemia
    - Elevated alkaline phosphatase
    - Elevated liver enzymes (AST, ALT)
    - Abnormal clotting (prothrombin time, international normalized ratio, partial thromboplastin time)
  – GI bleeding
    - Iron deficiency anemia
    - Elevated serum ammonia
    - Fecal occult blood
    - Thrombocytopenia
  – Hepatorenal syndrome
Elevated serum creatinine (Cr), blood urea nitrogen (BUN)
Urine Na <5 mEq/L (<20 mmol/L)
– US and CT scan/MRI may detect cirrhosis, splenomegaly, ascites, and varices.
– US/duplex Doppler
  o Can determine presence and direction of flow in portal and hepatic veins
  o Useful in diagnosing portal vein thrombosis, shunt thrombosis, or the presence of ascites
– CT scan/MRI: angiographic measurement of hepatic venous wedge pressure via jugular or femoral vein
  o Correlates with portal pressure
  o Risk of variceal bleeding is increased if HVPG >12 mm Hg.
– Upper GI series may outline varices in esophagus and stomach.
– Transient elastography is a noninvasive method to determine hepatic fibrosis and to predict portal hypertension (1).

Diagnostic Procedures/Other
• Diagnostic paracentesis and calculation of the serum-ascites albumin gradient (SAAG) can differentiate between portal hypertensive (SAAG >1.1 g/dL) from nonportal hypertensive (SAAG <1.1 g/dL) causes of ascites.
• Endoscopy can diagnose esophageal and gastric varices and portal hypertensive gastropathy.

Test Interpretation
Specific for underlying disease

TREATMENT

GENERAL MEASURES
• Avoid sedatives that may precipitate encephalopathy.
• Limit sodium intake because cirrhotic patients avidly retain sodium (<2 g sodium per day).

MEDICATION
Therapy for encephalopathy: See “Hepatic Encephalopathy.”

First Line
• Prophylaxis against variceal bleeding (2,3)[A]:
  – Nonselective β-blockade
    o Nadolol: 20 to 40 mg PO once-daily dosing
    o Propranolol: Start with 20 to 40 mg PO BID to TID.
  – May consider carvedilol: 6.25 mg PO once-daily dosing as an alternative β-blocker (4)[C]
  – Doses may be titrated up as tolerated to maximum recommended doses; goal resting heart rate of 55 to 60 bpm
• Therapy for acute variceal hemorrhage:
  – Octreotide: 50 μg IV bolus followed by 50 μg/hr continuous infusion; pediatric dose: 1 μg/kg bolus followed by 1 μg/kg/hr is used traditionally; treat for up to 5 days.
  – Vasopressin: Start with 0.2 to 0.4 U/min IV; increase to maximum dose 0.8 U/min as needed; pediatric dose: 0.002 to 0.005 U/kg/min; do not exceed 0.01 U/kg/min. After bleeding stops, continue at same dose for 12 hours and then taper off over 24 to 48 hours.
• For prevention of recurrence and for overall reduction in mortality:
- Nadolol: 40 to 80 mg/day PO reduces portal venous blood inflow by blocking the adrenergic dilatation of the mesenteric arterioles.
- Propranolol: 10 to 60 mg/day PO BID to QID; pediatric dose: 0.5 to 1.0 mg/kg/day PO divided q6–8h
- Tetrandrine, a calcium channel blocker, also has been found to reduce the rate of rebleeding with fewer side effects.
  - Initial treatment for ascites (along with salt and fluid restriction):
    - Furosemide: 20 to 40 mg/day PO; pediatric dose: 1 to 2 mg/kg/dose PO ± IV albumin infusion
    - Spironolactone: 50 to 100 mg/day PO; pediatric dose: 1 to 3 mg/kg/day PO

**Second Line**
- Terlipressin (2 mg IV q4h; titrate down to 1 mg IV q4h once hemorrhage is controlled; may be used for up to 48 hours) is a more selective splanchnic vasoconstrictor and may be associated with fewer complications. It is currently used when standard therapy with somatostatin or octreotide fails.
- Addition of nitrates, such as nitroglycerin or isosorbide mononitrate, reduces portal pressures and bleeding rates and has been shown to reduce mortality. Because the risk–benefit ratio is not clear, nitrates are not considered first-line treatment.
- Studies are ongoing for possible benefits of other agents including simvastatin, clonidine, verapamil, and losartan.

**ISSUES FOR REFERRAL**
Patients with portal hypertension should be managed longitudinally by both a primary care physician and a gastroenterologist.

**SURGERY/OTHER PROCEDURES**
- Treatments available for specific complications of portal hypertension (in addition to or if refractory to medications):
  - Gastroesophageal varices without hemorrhage
    o Endoscopic variceal ligation (EVL) is the preferred therapy for prevention of bleeding of large (grade III) varices and requires serial interventions every 2 to 8 weeks until the varices are eradicated.
  - Gastroesophageal varices with hemorrhage
    o EVL or sclerosis (the first-line treatment in many cases for acute hemorrhage) within 12 hours of presentation (5)[A]
    o Balloon tamponade (not used commonly when endoscopic treatment is available)
    o Transjugular intrahepatic portosystemic shunt (TIPS)
    o Portacaval shunting
  - Ascites refractory to medical management
    o Large-volume paracentesis
    o Peritoneovenous shunt
    o TIPS
- Liver transplantation should be considered for patients with advanced disease.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Acute GI bleeding should be managed in the inpatient setting, either on the regular medical floor if the patient is hemodynamically stable or in the ICU if the patient is unstable.
• Patients with mental status changes from encephalopathy need to be evaluated in the inpatient setting.
• Admission criteria/initial stabilization
  – Acute bleeding from the intestinal tract, either vomiting or per rectum
  – Acute confusional state/mental status changes
  – If acute variceal bleeding:
    o Type and cross patient’s blood.
    o Initial resuscitation with isotonic fluid until packed RBCs are available
    o Correct coagulopathy with vitamin K and fresh frozen plasma (FFP).
    o Endoscopy as soon as the patient is stabilized (for diagnosis and treatment)
  – Avoid sedatives that may precipitate encephalopathy.
  – Limit sodium administration because cirrhotic patients avidly retain sodium.
  – Restrict protein only if encephalopathic.

**ALERT**
If the patient is an active alcohol drinker, assess for alcoholic hepatitis and watch for signs and symptoms of withdrawal. Follow inpatient protocols for alcohol withdrawal management.

• Use isotonic fluid for hydration.
• Discharge criteria
  – For GI bleeding:
    o No active bleeding in 24 hours
    o Stable hemoglobin and hematocrit
    o Hemodynamically stable (especially heart rate)
  – For encephalopathy: improvement in or resolution of mental status changes to baseline

**ONGOING CARE**

**DIET**
In patients with cirrhosis, sodium restriction is important because cirrhotic patients avidly retain sodium.

**PATIENT EDUCATION**
Refrain from drinking alcohol. Resources for patients who have difficulty with not drinking alcohol can be obtained from Alcoholics Anonymous at [http://www.aa.org/](http://www.aa.org/).

**PROGNOSIS**
• Hepatic reserve defined by Child-Pugh classification: rating based on encephalopathy, ascites, bilirubin, albumin, prothrombin
• Variceal bleeding
  – 1/3 of patients with known varices will bleed eventually.
  – 50% rebleed, usually within 2 years, unless portal pressure is reduced by surgical or TIPS procedure.
  – 15–20% mortality rate
• Ascites and encephalopathy often recur.
• Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites).
REFERENCES

ADDITIONAL READING

CODES

ICD10
K76.6 Portal hypertension

CLINICAL PEARLS

- Portal hypertension can be diagnosed based on physical examination in the setting of known risk factors, specifically cirrhosis.
- Endoscopic treatment is successful for acute variceal hemorrhage 85% of the time.
- Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites).
- Advantages and disadvantages of balloon tamponade for acute variceal bleed:
  - Advantages include rapid and often effective control of bleeding (30–90%) and common availability of device.
  - Disadvantages include recurrence of bleeding when balloon is deflated, patient discomfort, and risk of esophageal perforation.
POSTCONCUSSION SYNDROME (MILD TRAUMATIC BRAIN INJURY)
Vicki R. Nelson, MD, PhD Joshua Pacious, MD

BASICS

DESCRIPTION
• Postconcussion syndrome (PCS) is a constellation of symptoms involving physical, cognitive, and/or behavioral symptoms persisting after a concussion (mild traumatic brain injury [mTBI]) that may continue for weeks to years (1).
• It is unclear when concussive symptoms transition to become postconcussive syndrome. A recent consensus defines this as persistent symptoms lasting >10 to 14 days in adults and 4 weeks in children (2).
• Symptoms of PCS include (1)
  – Cognitive
    o Poor focus
    o Poor organization
    o Diminished academic/intellectual performance
    o Slowed response time
  – Physical
    o Headache
    o Nausea
    o Visual changes
    o Light and noise sensitivity
    o Tinnitus
    o Dizziness and balance problems
    o Fatigue and sleep disturbance
  – Behavioral
    o Depression
    o Irritability/emotional lability
    o Apathy
    o Increased sensitivity to alcohol
• Diagnosis is based on history and clinical symptoms.

EPIDEMIOLOGY

Incidence
The reported range of mTBI patients who develop PCS varies widely between 5% and 80%. Largely due to difficulty differentiating postconcussion symptoms from PCS
• 80–90% of concussion victims recover from postconcussion symptoms within 7 to 10 days, slightly longer in children/adolescents (2). A diagnosis of PCS is made in patients with persistent concussive symptoms.

Prevalence
Predominant sex: female > male. Female gender is not universally considered a risk factor.
ETIOLOGY AND PATHOPHYSIOLOGY
- Controversial; exact mechanism(s) unknown
- Microscopic axonal injury from shearing forces leads to inflammation causing secondary brain injury.
- Conflicting data on structural brain damage and correlation of imaging with physical symptoms (1)
- Because the pathophysiology of PCS is not well understood and because of symptom overlap with other psychiatric conditions, PCS remains difficult to diagnose and to manage.
  - Only some with mTBI develop PCS; it is unclear what causes PCS symptoms to persist.
  - Behavioral factors are commonly associated with (and may play a role in) the development of PCS. It can be challenging to differentiate some behavioral disorders from PCS (1).
  - Neuropsychiatry evaluation helps differentiate PCS from other behavioral disorders.
  - Patients who reported high symptom burden following mTBI are at increased risk of PCS (3)[B].

RISK FACTORS
- Strongest predictor is severity of initial symptoms (2).
- Increased odds of PCS if initial symptoms include retrograde amnesia, difficulty concentrating, disorientation, insomnia, loss of balance, sensitivity to noise, or visual disturbance (4)
- Preexisting psychiatric disease including depression, anxiety, personality disorder, and posttraumatic stress disorder (PTSD) increase the risk of developing PCS
- Preexisting expectation of poor outcomes following mTBI (1)
- Nonsport concussion/mTBI
- Unclear if previous history of concussion(s) is a risk factor for PCS
- Low socioeconomic status
- Loss of consciousness not predictive of PCS

GENERAL PREVENTION
- Education of players, coaches, parents, and athletic trainers about concussion, PCS, and appropriate safety rules
- Head injury precautions are advised. Evidence is lacking that these decrease incidence of mTBI/PCS.
- Screening and intervention for anxiety and depression

COMMONLY ASSOCIATED CONDITIONS
- PTSD
- Anxiety
- Depression
- Fibromyalgia
- Personality disorders (namely, compulsive, histrionic, and narcissistic)
- ADHD

DIAGNOSIS

HISTORY
- Detailed history of recent impact and closed head injury, including:
– Mechanism
– Timing of injury related to symptoms
– Previous head injuries, including concussion, and timing of those injuries
– Previous medical, psychiatric, or social history
– Thorough characterization of associated symptoms, intensity, and duration

● Report of neurologic, cognitive, or behavioral symptoms by patient/family

**PHYSICAL EXAM**
Complete neurologic exam, including the following:

● Glasgow Coma Scale (GCS)
● Anxiety/depression screening
  – Patient Health Questionnaire-9 (PHQ-9)
  – GAD-7
● Sport Concussion Assessment Tool (SCAT), NFL Sideline Concussion Assessment Tool, or computerized neuropsychological (CNP) testing ([2])

**DIFFERENTIAL DIAGNOSIS**

● Postconcussive symptoms
● PTSD
● Anxiety/depression
● Personality disorders
● Migraine headaches
● Chronic fatigue syndrome, fibromyalgia
● Evolving intracranial hemorrhage
● Exposure to toxins, including prescription and recreational drugs
● Endocrine/metabolic abnormality

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

● Consider infection, intoxication, and endocrine or metabolic abnormality in appropriate clinical setting.
● Brain imaging both on initial evaluation of mTBI and PCS is not routinely indicated.
● Imaging to evaluate for bleeding is appropriate with comorbidities or anticoagulation therapy.
● Imaging indicated if cervical spine injury is suspected

**Follow-Up Tests & Special Considerations**

● Several CNP tests are available to help guide return-to-play decisions; it is most useful to compare with baseline scores (if available).
● Formal neuropsychiatric evaluations are superior to CNP testing when available. None of these tests should be used in isolation for decision making, especially if a patient is still symptomatic ([1,2][C].
● Common neuropsychological testing programs
  – Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT)
  – Post-Concussion Symptom Scale (PCSS)
  – Balance Error Scoring System (BESS)
  – Axon Sports Computerized Cognitive Assessment Tool (CCAT)
  – Automated Neuropsychological Assessment Metrics (ANAM)
TREATMENT

GENERAL MEASURES
- Return to full activity should progress according to existing evidence-based recommendations, which include immediate cognitive rest in the acute period (24 to 48 hours) followed by gradual return to daily activities as tolerated (1,2)[C].
- When possible, controlling cognitive stress and providing extra school accommodations can be beneficial (2).
- Restrict individuals with concussion or PCS from sport activity until symptoms have resolved and patients have been weaned from any medications that might mask PCS symptoms (1,2)[C].
- Physical therapy for coexisting cervical and vestibular injuries is beneficial. Cognitive-behavioral therapy helps with persistent mood disturbances (3).
- Limited evidence that pharmacotherapy is beneficial
- Subthreshold exercise helps resolve symptoms (5)[B].

MEDICATION

First Line
- Headache/neck pain
  - Nonopioid pain control (e.g., NSAIDs) preferred
    o With use of opioid medications, sedation obscures cognitive evaluation.
    o Possible association between the use of opiates and increased risk of anxiety/depression in PCS patients
    o Consider occipital nerve block.
  - Propranolol or amitriptyline alone or in combination (6)
- Emotional dysregulation (irritability, sadness, anxiety, depression)
  - Anxiety/depression screening starting in the 1st week post-mTBI
    o Tricyclic antidepressants (e.g., amitriptyline 10 to 25 mg at night)
    o SSRIs (e.g., sertraline 25 mg daily titrated to effective dose with maximum 200 mg daily) for persistent depressive symptoms (7)
  - Consider referral to behavioral health specialist(s).
- Sleep dysregulation
  - Sleep hygiene
  - Melatonin (up to 3 mg in older children and 5 mg in adolescents and adults)
  - Trazodone (25 to 50 mg at night)
- Cognitive disorders (poor concentration, fogginess, drowsiness)
  - Neuropsychological evaluation
  - Neurostimulants, such as amantadine (100 mg BID) (8), methylphenidate, atomoxetine
- Emotional disturbances

ISSUES FOR REFERRAL
- Neuropsychiatric therapy including comprehensive cognitive evaluation for potential TBI rehabilitation
- Cognitive-behavioral therapy for anxiety and depression symptoms
- Occupational therapy for vocational rehabilitation
- Physical therapy for vestibular rehabilitation
Neurology referral if primary care interventions for seizures, headache, vertigo, or cognition are unsuccessful
- Substance abuse counseling, if needed

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Massage therapy/osteopathic manipulative treatment for headache and neck pain
- Potential benefits shown with hyperbaric oxygen therapy in military veterans with concurrent PCS and PTSD

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Schedule regular follow-up to evaluate for persistent symptoms, efficacy of and/or need for neuropsychiatric evaluation, and the efficacy of and/or need for pharmacologic therapy.

Patient Monitoring
- Consider serial neuropsychological testing.
- Follow return-to-play guidelines (2)[C].

PATIENT EDUCATION
- Centers for Disease Control and Prevention: http://www.cdc.gov/headsup/
- Brain Injury Association of America: http://www.biausa.org/; (800) 444-6443

PROGNOSIS
- Prognosis generally is good. Most patients improve within 3 months.
- Adolescents may recover more slowly than adults.

COMPLICATIONS
- Repeat head injury or return to play before resolution of PCS can worsen/prolong symptoms.
- Case studies of second-impact syndrome, a rare but potentially fatal condition owing to a second head injury soon after the first, have been reported.

SEE ALSO
- Concussion (Mild Traumatic Brain Injury)

CODES

ICD10
- F07.81 Postconcussional syndrome
- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init
- S06.9X9A Unsp intracranial injury w LOC of unsp duration, init

CLINICAL PEARLS
- Imaging rarely useful for post-concussion syndrome. If necessary, head CT scan is the test of choice for acute injury to exclude intracranial bleeding.
- Coordinate multidisciplinary treatment plans for patients with persistent symptoms.
- Return to play/activity should not occur until the athlete is asymptomatic (or has returned to pre-event baseline).
POSTTRAUMATIC STRESS DISORDER (PTSD)
Crystal Haydee Chavez, MD ● Fozia Akhtar Ali, MD ● Chi Nguyen Stasio, DO

BASICS
DESCRIPTION
- Posttraumatic stress disorder (PTSD) is an anxiety disorder defined as a reaction that can occur after exposure to an extreme traumatic event involving death, threat of death, serious physical injury, or a threat to physical integrity.
- This reaction has three cardinal characteristics:
  - Reexperiencing the trauma
  - Avoidance of anything related to the traumatic event and/or numbing of general responsiveness
  - Increased arousal
- Traumatic events that may trigger PTSD include natural/human disasters, serious accidents, war, sexual abuse, rape, torture, terrorism, hostage taking, or being diagnosed with life-threatening disease.
- PTSD can be:
  - Acute: symptoms lasting <3 months
  - Chronic: symptoms lasting ≥3 months
  - Delayed: onset 6 months after trauma exposure, <5% of cases
  - Subclinical: waxing and waning course

EPIDEMIOLOGY
- ~30% of men and women who have spent time in a war zone experience PTSD.
- 4 of the 6 trauma types associated with highest population proportions of lifetime PTSD episodes are related to intimate partner sexual violence.
- 16% children and adolescents exposed to trauma develop PTSD.

Incidence
~7.7 million American adults aged ≥18 years (3.5% of this age group) are diagnosed with PTSD each year.

Prevalence
Lifetime prevalence for PTSD ranges from 6.8% to 12.3% in the general population.

ETIOLOGY AND PATHOPHYSIOLOGY
- Biologic dimensions: Hyperactivity/hypersensitivity of catecholamine pathways and overactivity/oversensitivity of the central opioid pathways is seen; the amygdala and hippocampus dysfunction, with possible atrophy from overexposure to catecholamines, serotonergic dysregulation, glutamatergic dysregulation, and increased thyroid activity
- Learning theory: Life-threatening fear is classically conditioned by event exposure; any internal or external cue reminiscent of the event produces an intense “fight or flight” fear response. The person avoids cues that trigger fear. This avoidance maintains fear.
- Cognitive theories: These models suggest that severe trauma becomes represented in complex
memory structures. The activation of these memories triggers intense thoughts and emotions that are pathologic (causing personal discomfort and dysfunction).

- Psychodynamic theory: Traumatic memories overwhelm defense mechanisms. Repeated recall of the traumatic event with associated fear is an effort to understand the event in a less threatening way.

**Genetics**

Monozygotic twins exposed to combat in Vietnam were at increased risk of the co-twin having PTSD compared with twins who were dizygotic.

**RISK FACTORS**

- Pretrauma environment:
  - Female gender
  - Younger age
  - Psychiatric history
  - Sexual abuse
- Peritrauma environment:
  - Severity of the trauma
  - Peritrauma emotionality
  - Perception of threat to life
  - Perpetration of the trauma
- Posttrauma environment:
  - Perceived injury severity
  - Medical complications
  - Perceived social support
  - Persistent dissociation from traumatic event
- Subsequent exposure to trauma-related stimuli

**GENERAL PREVENTION**

- Trauma-focused cognitive-behavioral therapy (CBT) and modified prolonged exposure delivered within weeks of a potentially traumatic event for people showing signs of distress have the most evidence in the treatment of acute stress and early PTSD symptoms and the prevention of PTSD.

**COMMONLY ASSOCIATED CONDITIONS**

- Major depressive disorder
- Alcohol/substance abuse
- Panic disorder
- Obsessive-compulsive disorder
- Agoraphobia and/or social phobia
- Traumatic brain injury
- Smoking (especially with assaultive trauma)
- Major neurocognitive disorders, dementia, or amnesia

**Pediatric Considerations**

Oppositional defiant disorder and separation anxiety are common comorbid conditions.
**DIAGNOSIS**

**HISTORY**

Diagnosis is based on DSM-5 criteria:

- **Criterion A:** exposure to trauma (≥1 of the following):
  - Direct experience of a traumatic event
  - In-person witnessing of a traumatic event
  - Learning of a traumatic event involving a close friend or family member
  - Repeated exposure to details of a traumatic event

- **Criterion B:** intrusive symptoms associated with the traumatic event (≥1 of the following):
  - Recurrent, involuntary, and intrusive distressing memories of the event
  - Recurrent distressing dreams related to the event
  - Dissociative reactions that simulate a recurrence of the event
  - Intense or prolonged distress to stimuli that resemble an aspect of the event

- **Criterion C:** avoidance of stimuli associated with the trauma (≥1 of the following):
  - Avoidance of memories, thoughts, or feelings about the event
  - Avoidance of external reminders that trigger memories, thoughts, or feelings about the event

- **Criterion D:** negative cognitive and mood changes associated with the trauma (≥2 of the following):
  - Inability to remember aspects of event
  - Persistent and exaggerated negative opinion of self, others, or the world
  - Distorted beliefs about the cause or consequences of the event
  - Negative emotional state
  - Diminished interest in significant activities
  - Feeling detached from others
  - Inability to experience positive emotions

- **Criterion E:** hyperarousal (≥2 of the following):
  - Difficulty sleeping/falling asleep
  - Decreased concentration
  - Hypervigilance
  - Outbursts of anger/irritable mood
  - Exaggerated startle response
  - Self-destructive behavior

- **Criterion F:** Duration of the relevant criteria symptoms should be >1 month.

- **Criterion G:** clinically significant distress/impairment in functioning

- **Criterion H:** relevant criteria not attributed to substance effects or other medical conditions

**Pediatric Considerations**

- Memories of the traumatic event may not appear distressing and may be seen as play reenactment.
- Reactions can include a fear of being separated from a parent, crying, whimpering, screaming, immobility and/or aimless motion, trembling, frightened facial expressions, excessive clinging, or regressive behavior.
- Older children may show extreme withdrawal, disruptive behavior, and/or an inability to pay attention. Regressive behaviors, nightmares, sleep problems, irrational fears, irritability,
refusal to attend school, outbursts of anger, fighting, somatic complaints with no medical basis, and decline in schoolwork performance. Furthermore, depression, anxiety, feelings of guilt, and emotional numbing are often present.

- Parental posttraumatic stress has been shown to be a robust predictor of pediatric PTSD (1)[A].

**PHYSICAL EXAM**

- Patients may present with physical injuries from the traumatic event.
- Mental status examination:
  - Thoughts and perceptions (e.g., hallucinations, delusions, suicidal ideation, phobias)
  - General appearance: disheveled, poor hygiene
  - Behavior: agitation; startle reaction extreme
  - Psychological numbness
  - Orientation may be affected.
  - Memory: forgetfulness, especially concerning the details of the traumatic event
  - Poor concentration
  - Poor impulse control
  - Altered speech rate and flow
  - Mood and affect may be changed: depression, anxiety, guilt, and/or fear.

**Pediatric Considerations**

Elevated heart rate immediately following trauma is associated with development of PTSD (1)[A].

**DIFFERENTIAL DIAGNOSIS**

- Acute stress disorder (symptoms <4 weeks)
- Generalized anxiety disorder
- Adjustment disorder
- Obsessive-compulsive disorder
- Schizophrenia
- Major depressive disorder
- Mood disorder with psychotic features
- Substance abuse
- Personality disorders
- Dissociative disorders
- Conversion disorder

**TREATMENT**

Combination psychotherapy and pharmacotherapy, initiated soon after the trauma, results in better prognosis.

**MEDICATION**

**First Line**

- Depression, panic attacks, startle response, sleep disruption: may improve with SSRIs (2)[A].
  
  All commonly used SSRIs have been shown to be effective.
  
  - Sertraline: 50 to 200 mg every day (FDA-approved)
– Paroxetine: starting dose: 10 mg every day; may be increased in 10 mg increments at intervals ≥1 week (FDA-approved)
– Fluoxetine: 20 mg every day/BID not to exceed 80 mg/day (demonstrates some efficacy for all three symptom clusters)

Sleep disruption: Sleep disruption due to hyper arousal is ubiquitous in PTSD; standard sedatives, such as trazodone 50 to 300 mg at bedtime, mirtazapine 7.5 to 30.0 mg QHS, or amitriptyline 25 to 100 mg QHS

Nightmares/nighttime hyperarousal: prazosin 2 to 15 mg QHS (3)[A], clonidine 0.1 to 0.2 mg QHS, amitriptyline 25 to 100 mg QHS

Second Line
Refractory/residual symptoms: Consider augmentation with:

– Depression: mirtazapine 15 to 45 mg/day; consider switch to a serotonin norepinephrine reuptake inhibitor (SNRI), such as venlafaxine XR 37.5 to 300.0 mg/day, duloxetine 60 to 120 mg/day, or desvenlafaxine 50 to 100 mg/day. Nefazodone 300 to 600 mg/day in divided doses can be very effective but requires quarterly LFTs.

– Reexperiencing/intrusive thoughts: 1st-/2nd-generation antipsychotic medications: aripiprazole 5 to 15 mg/day, risperidone 0.5 to 2.0 mg/day, olanzapine 2.5 to 10.0 mg/day, quetiapine 50 to 400 mg/day (4)[A]. 2nd-generation Rx less prone to extrapyramidal symptoms (EPS): cognitive dulling

– Hyperarousal: clonidine, start 0.05 mg BID/TID; slowly titrate to as much as 0.45 mg/day divided doses; guanfacine 1 to 3 mg/day in divided doses (long-acting forms of both clonidine and guanfacine now available). Also consider 2nd-generation antipsychotics quetiapine, risperidone, and olanzapine as above; divided doses often more helpful

– Impulsivity/explosiveness: anticonvulsants: valproic acid 500 to 2,000 mg/day, carbamazepine 200 to 600 mg/day, topiramate 50 to 200 mg/day

– Anxiety: Benzodiazepines (especially short-acting) should be avoided given the risk of substance abuse and questionable benefit in PTSD (5)[A]. Consider hydroxyzine 25 to 50 mg TID/QID PRN or risperidone 0.25 to 0.50 mg TID PRN.

ADDITIONAL THERAPIES

– Psychotherapeutic interventions:
  – Exposure therapies have shown the highest effectiveness for treatment of PTSD (6)[A]:
    o Behavioral and CBT: Early CBT, including virtual exposure, has been shown to speed recovery. CBT is considered the standard of care for PTSD by the U.S. Department of Defense.
    o 1-week intensive CBT was as effective as 3 months weekly CBT in one study.
    o Prolonged exposure therapy: Reexperience distressing trauma-related memories and reminders to facilitate habituation and successful emotional processing of memory.
    o Eye movement desensitization and reprocessing (EMDR) has been shown to benefit patients with PTSD.
  – Stress-reduction techniques:
    o Immediate symptom reduction (e.g., rebreathing in a bag for hyperventilation)
    o Early recognition and removal from a stress
    o Relaxation, meditation, and exercise techniques are also helpful in reducing the reaction to stressful events.
  – Telemedicine-based collaborative care (nurse, case manager, pharmacy, psychology,
psychiatry) is more effective than usual care.

- Interpersonal psychotherapy:
  - Supportive psychotherapy with an emphasis on the here and now
- Social:
  - Consider social and/or spiritual support for trauma survivors.

**Pediatric Considerations**

There is very little evidence to support use of pharmacologic interventions for pediatric PTSD.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Inpatient care is necessary only if the patient becomes suicidal/homicidal or for treatment of comorbid conditions (e.g., uncontrolled psychosis, substance abuse).

**ONGOING CARE**

**PATIENT EDUCATION**

National Center for PTSD: [www.ptsd.va.gov](http://www.ptsd.va.gov)

**PROGNOSIS**

- In 50% of cases, the symptoms spontaneously remit after 3 months; however, in other cases, symptoms may persist, often for many years, and cause long-term impairment in life functioning.
- Factors associated with a good prognosis include:
  - Rapid engagement of treatment
  - Early and ongoing social support
  - Avoidance of retraumatization
  - Absence of other psychiatric disorders/substance abuse

**COMPLICATIONS**

- Increased risk for panic disorder, agoraphobia, obsessive-compulsive disorder, social phobia, specific phobia, major depressive disorder, somatization disorder; impulsive behavior, suicide, and homicide
- Victims of sexual assault are at especially high risk for developing mental health problems and committing suicide.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- F43.10 Post-traumatic stress disorder, unspecified
- F43.11 Post-traumatic stress disorder, acute
- F43.12 Post-traumatic stress disorder, chronic

CLINICAL PEARLS

- Symptoms usually wax and wane over the years.
- Treatment is often best accomplished with a combination of psychotherapy and pharmacotherapy.
PREECLAMPSIA AND ECLAMPSIA (TOXEMIA OF PREGNANCY)
Ann M. Aring, MD, FAAFP

BASICS

DESCRIPTION

- **Preeclampsia:**
  - A disorder of pregnancy occurring after 20 weeks’ gestation characterized by new-onset hypertension (HTN), new-onset proteinuria, ± impaired organ function:
    - May progress from mild to life-threatening in hours to days
    - Reversible by delivery

- **Eclampsia:**
  - New-onset grand mal seizure activity with no history of underlying neurologic disease

- Most postpartum cases of preeclampsia and eclampsia occur within 48 hours of delivery but can occur up to 4 weeks postpartum.
- System(s) affected: cardiovascular, renal, reproductive, fetoplacental, CNS, hepatic, pulmonary
- Synonym(s): toxemia of pregnancy

EPIDEMIOLOGY

Prevalence

- Predominant age
  - Most in younger women, primiparous women
  - Older (>40 years) patients with preeclampsia have 4 times the incidence of seizures compared with patients in their 20s.

- Preeclampsia occurs in 5–8% of all pregnancies.
- Eclampsia occurs:
  - 1.6 to 10 out of 10,000 deliveries in developed countries
  - 6 to 157 out of 10,000 deliveries in developing countries
- 40% of eclamptic seizures occur before delivery; 16% occur >48 hours after delivery.
- Eclampsia is a main cause of perinatal mortality and morbidity (2–8% of all pregnancies).

ETIOLOGY AND PATHOPHYSIOLOGY

- Cause of preeclampsia is becoming clearer.
  - Abnormal placental implantation
  - Angiogenic factors
  - Genetic predisposition
  - Immunologic phenomena
  - Vascular endothelial damage and oxidative stress

- Systemic derangements in eclampsia include the following:
  - Cardiovascular: generalized vasospasm
  - Hematologic: decreased plasma volume, increased blood viscosity, hemoconcentration, coagulopathy
  - Renal: decreased glomerular filtration rate
Hepatic: periportal necrosis, hepatocellular damage, subcapsular hematoma
CNS: cerebral vasospasm and ischemia, cerebral edema, cerebral hemorrhage

**Genetics**
2 to 4 times increased risk in pregnant women with family history of preeclampsia

**RISK FACTORS**
- Nulliparity
- Age >40 years
- Family history of preeclampsia
- High body mass index
- Diabetes
- Chronic HTN
- Chronic renal disease
- Multifetal pregnancy
- Previous pregnancy with preeclampsia
- Systemic lupus erythematosus
- In vitro fertilization

**GENERAL PREVENTION**
- Adequate prenatal care
- Inadequate prenatal care results in 7 times increase in mortality.
- Good control of preexisting HTN
- Low-dose aspirin (ASA) (60 to 80 mg):
  - ASA started early after 12 weeks’ gestational age (GA) may lower the risk of developing preeclampsia and the rate of preterm delivery and neonatal death in moderate- to high-risk patients (see “Risk Factors” as mentioned earlier) (1)[A].
- Low-dose calcium supplementation has been shown to reduce the risk and severity of preeclampsia in calcium-deficient populations (1)[A].
- Some evidence suggests vitamin C (1,000 mg/day) and vitamin E (400 IU/day) may reduce the risk for preeclampsia, but recent guidelines recommend against their use.

**COMMONLY ASSOCIATED CONDITIONS**
Abruptio placentae, placental insufficiency, fetal growth restriction, preterm delivery, fetal demise maternal seizures (eclampsia), maternal pulmonary edema, maternal liver/kidney failure, or maternal death

**DIAGNOSIS**
- Preeclampsia diagnosis:
  - New-onset elevated blood pressure (BP): systolic BP (SBP) ≥140 mm Hg or diastolic BP (DBP) ≥90 mm Hg (on two occasions at least 4 hours apart) or ≥160/110 mm Hg after 20 weeks of gestation (within a shorter interval), and either
    - Proteinuria (>300 mg/24 hr or spot protein: creatinine ≥0.3) or
    - New-onset thrombocytopenia, renal insufficiency, impaired liver function, pulmonary edema, or cerebral/visual symptoms (1)[C]
  - Define preeclampsia as either without or with severe features. The presence of new onset of
one or more of below defines severe features (1):
  - BP ≥160/110 mm Hg
  - Platelets <100,000/μL
  - >2 times normal liver transaminase levels, severe persistent right upper quadrant (RUQ)/epigastric pain, or both
  - Creatinine >1.1 mg/dL or doubling of serum creatinine levels
  - Pulmonary edema
  - Cerebral or visual symptoms

- Eclampsia diagnosis:
  - New-onset grand mal seizure
  - No history of neurologic disease

**HISTORY**
- May be asymptomatic. In some cases, rapid excessive weight gain (>5 lb/week; >2.3 kg/week); more severe cases are associated with epigastric/RUQ pain, headache, altered mental status, and visual disturbance. Note: Headache, visual disturbance, and epigastric or RUQ pain often precede seizure.
- Seizures may occur once/repeatedly.

**PHYSICAL EXAM**
BP criteria:
- Preeclampsia without severe features: elevated BP ≥140/90 mm Hg
- Preeclampsia with severe features: Elevated BP ≥160 systolic mm Hg or 110 mm Hg diastolic
- Eclampsia: tonic–clonic seizure activity (focal/generalized)
- Normal BP, even in response to treatment; does not rule out potential for seizures

**DIFFERENTIAL DIAGNOSIS**
- Chronic HTN: HTN before pregnancy; high BP before the 20th week
- Chronic HTN with superimposed preeclampsia
- Gestational HTN: Increased BP first discovered after 20 weeks, often close to term, with no proteinuria and without evidence of organ dysfunction. BP becomes normal by 12 weeks postpartum, or it is reclassified as chronic HTN.
- Seizures in pregnancy: epilepsy, cerebral tumors, meningitis/encephalitis, and ruptured cerebral aneurysm. Until other causes are proven; however, all pregnant women with convulsions should be considered to have eclampsia.

**DIAGNOSTIC TESTS & INTERPRETATION**
**Initial Tests (lab, imaging)**
- Routine spot urine testing or urinalysis for protein should be done at each prenatal visit in all hypertensive patients.
- Complete blood count (CBC), including platelets, creatinine, serum transaminase levels, and uric acid as baseline in hypertensive patients and if preeclampsia suspected or possible
- Coagulation profiles: Abnormalities suggest severe disease.
- 24-hour urine or protein/creatinine ratio if urine protein dips 1+ on more than one occasion, or if preeclampsia is being considered
- Daily fetal movement monitoring by mother (“kick counts”)
- US imaging is used to monitor growth and cord blood flow; perform, as indicated, based on clinical stability and laboratory findings.
Follow-Up Tests & Special Considerations
Disseminated intravascular coagulation, thrombocytopenia, liver dysfunction, and renal failure can complicate preeclampsia associated with HELLP syndrome.

Test Interpretation
CNS: cerebral edema, hyperemia, focal anemia, thrombosis, and hemorrhage. Cerebral lesions account for 40% of eclamptic deaths.

TREATMENT

GENERAL MEASURES
- Preeclampsia without severe features:
  - Outpatient care
  - Maternal: daily home BP monitoring; daily weights; weekly labs (CBC, creatinine, liver function test [LFT])
  - Fetal:
    - Patient-measured: daily “kick counts”
    - NST/BPP/US (see imaging section above)
    - Delivery at 37 weeks (induction of labor) (1,2)[C]
    - Steroids for gestation <37 weeks
- Preeclampsia with severe features:
  - Inpatient care
  - Maternal:
    - Daily labs
    - IV magnesium sulfate (MgSO₄) as seizure prophylaxis
    - Antihypertensive therapy titrated to keep SBP <160 mm Hg and DBP <110 mm Hg (some recommend <150/100 mm Hg postpartum)
  - Fetal:
    - Continuous heart monitoring
    - Daily US with BPP
    - Check amniotic fluid levels and fetal growth.
  - Definitive management (delivery) depends on GA (1,2)[C].
  - <23 weeks:
    - Offer to terminate pregnancy.
  - At 23 to 34 weeks:
    - Antihypertensives
    - Evaluate maternal–fetal condition.
    - Steroids to enhance fetal lung maturity
    - Plan delivery at 34 weeks with magnesium sulfate prophylaxis.
If HELLP syndrome (full or partial), severe oligohydramnios, significant renal dysfunction, persistent symptoms, fetal growth restriction, onset of labor, OR PROM, proceed to delivery.

- At ≥34 weeks: magnesium sulfate, steroids, and proceed to delivery (1)[C]; steroids indicated up to 37 weeks

**ALERT**

- Regardless of GA, emergent delivery is recommended if there are signs of maternal hypertensive crisis, abruptio placentae, uterine rupture, or fetal distress.
- Seizures: control of convulsions, correction of hypoxia and acidosis, lowering of BP, steps to effect delivery as soon as convulsions are controlled
- Administer betamethasone 12 mg IM daily × 2 doses or dexamethasone 6 mg every 12 hours × 4 doses if delivery <37 weeks possible.

**MEDICATION**

**First Line**

- Seizure prophylaxis for women with severe preeclampsia:
  - Magnesium sulfate: loading dose 4 g IV in 200 mL normal saline over 20 to 30 minutes; maintenance dose 1 to 2 g/hr IV continuous infusion (Although recent guidelines suggest it not be universally administered for seizure prophylaxis to prevent eclampsia, the quality of the evidence is low, and the strength of the recommendation is qualified.) (1)[C]

- BP control (3):
  - Antihypertensives are inadvisable for mildly elevated BP (without severe features).
  - Labetalol (IV): 20 mg over 2 minutes followed at 20- to 30-minute intervals with doses of 20 to 80 mg titrated to keep BP <160/110 mm Hg; max of 300 mg/24 hr (contraindicated in asthma, heart disease, congestive heart failure)
  - Hydralazine (IV): 5 to 10 mg over 2 minutes, followed at 20-minute intervals with 5 to 10 mg IV boluses; titrated to keep BP <160/110 mm Hg; max of 25 mg/24 hr
  - Nifedipine: immediate release 10 mg oral followed by 20 mg in 20 minutes if needed for severe range. Sustained release (PO) (used in the postpartum): 30 to 120 mg/day (caution with combination of nifedipine and magnesium sulfate resulting in hypotension and neuromuscular blockade) (4)[A]

- Eclampsia/seizures:
  - Magnesium sulfate for seizures
    - 4 to 6 g IV over 15 to 20 minutes followed by 1 to 2 g/hr infusion
    - Further boluses of magnesium may be given for recurrent convulsions with the amount given based on the neurologic examination and patellar reflexes.
    - Contraindications: myasthenia gravis, renal failure, pulmonary edema
  - Levels of 6 to 8 mEq/mL are considered therapeutic, but monitor clinical status of:
    - Patellar reflexes are present.
    - Respirations are not depressed.
    - Urine output is ≥25 mL/hr.
  - May be given safely, even in the presence of renal insufficiency

- Fluid therapy
  - Ringer lactated solution with 5% dextrose at 60 to 120 mL/hr, with careful attention to fluid volume status

- Calcium gluconate or chloride (1 g, administered slowly IV) may reverse magnesium-induced...
respiratory depression (1,2)[C].

**Second Line**
- In randomized trials, magnesium sulfate was found to be superior to phenytoin in treatment and prevention of eclampsia and probably more effective and safer than diazepam.
- Diazepam 2 mg/min until resolution or 20 mg given or
- Lorazepam 1 to 2 mg/min up to total of 10 mg or
- Phenytoin 15 to 20 mg/kg at a maximum rate of 50 mg/min or
- Levetiracetam 500 mg IV or oral may be repeated in 12 hours (dose needs to be adjusted in renal impairment) or
- Phenyobarbital 20 mg/kg infused at 50 mg/min; may repeat with additional 5 to 10 mg/kg after 15 minutes

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Without severe features: restricted activity and close monitoring; with severe features: restricted activity, in hospital
- Women with a history of preeclampsia should report this to physicians caring for them in later life. It is a potent cardiovascular disease risk factor.

**DIET**
- Salt restriction is inadvisable because the patient often is experiencing intravascular hypovolemia.
- Calcium supplementation may be recommended for women who have low calcium intake (<600 mg/day).

**PATIENT EDUCATION**
American College of Obstetricians and Gynecologists, 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; [http://www.acog.org/](http://www.acog.org/)

**PROGNOSIS**
- For nulliparous women with preeclampsia before 30 weeks of gestation, the recurrence rate for the disorder may be as high as 40% in future pregnancies.
- 25% of eclamptic women will have HTN during subsequent pregnancies, but only 5% of these will be severe and only 2% will be eclamptic again.
- Preeclamptic, multiparous women may be at higher risk for subsequent essential HTN; they also have higher mortality during subsequent pregnancies than do primiparous women.

**COMPLICATIONS**
- Most women do not have long-term sequelae from eclampsia, although many may have transient neurologic deficits.
- A history of preeclampsia is equivalent to traditional risk factors for cardiovascular disease. Women with a history of preeclampsia should be strongly advised to avoid obesity and smoking. Other signs of metabolic syndrome should be closely monitored as well.
- Intrauterine growth restriction (IUGR)
- Maternal and/or fetal death
REFERENCES

ADDITIONAL READING

CODES

ICD10

- O14.90 Unspecified pre-eclampsia, unspecified trimester
- O15.00 Eclampsia in pregnancy, unspecified trimester
- O14.00 Mild to moderate pre-eclampsia, unspecified trimester

CLINICAL PEARLS

- Management of preeclampsia depends on both the severity of the condition and the GA of the fetus.
- Magnesium sulfate is the treatment of choice for women demonstrating preeclampsia with severe features.
- Low-dose ASA starting in early pregnancy in high-risk patients may lower rate of preeclampsia.
- Continue to monitor maternal BP postpartum—still at risk for developing preeclampsia.
PREMENSTRUAL SYNDROME (PMS) AND PREMENSTRUAL DYSPHORIC DISORDER (PMDD)

Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION
- Premenstrual syndrome (PMS), a complex of physical and emotional symptoms sufficiently severe to interfere with everyday life, occurs cyclically during the luteal phase of menses.
- Premenstrual dysphoric disorder (PMDD) is a severe form of PMS characterized by severe recurrent depressive and anxiety symptoms, with premenstrual (luteal phase) onset, that remits a few days after the start of menses.
- PMDD is now included as a full diagnostic category in the 5th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5).
- System(s) affected: endocrine/metabolic, nervous, reproductive

EPIDEMIOLOGY

Prevalence
- Many women have some physical and psychological symptoms before menses (this is not PMS).
- Premenstrual disorders affect up to 12% of the U.S. population (1). 3–8% of menstruating women have PMDD.

ETIOLOGY AND PATHOPHYSIOLOGY

Not well understood. Leading theories postulate metabolites of progesterone interact with central neurotransmitter receptors (serotonin and γ-aminobutyric acid [GABA]), provoking downstream effects of decreased GABA-mediated inhibition and decreased serotonin levels. Women with PMS/PMDD have similar levels of progesterone but seem to have an increased sensitivity to its metabolites, compared with women without PMS/PMDD.

Genetics
- Role of genetic predisposition is controversial; however, twin studies do suggest a genetic component.
- Involvement of gene coding for the serotonergic 5HT1A receptor and allelic variants of the estrogen receptor-α gene (ESR1) is suggested.

RISK FACTORS
- Age: usually present in late 20s to mid-30s
- History of mood disorder (major depression, bipolar disorder), anxiety disorder, personality disorder, or substance abuse
- Family history
- Low parity
- Tobacco use
- Psychosocial stressors/history of trauma
- High BMI
DIAGNOSIS

HISTORY

- DSM-5 criteria (1):
  - Symptoms occur 1 week before menses, improve in the first few days after menses begin, and are minimal/absent in the week following menses (over most menstrual cycles during the past year).
  - ≥5 of the following (1 must be among the first 4):
    - Marked depressed mood, feelings of hopelessness, or self-deprecatimg thoughts
    - Marked anxiety, tension, and/or feelings of being keyed up or on edge
    - Marked affective lability (mood swings)
    - Marked irritability or anger or increased interpersonal conflicts
    - Decreased interest in usual activities and social withdrawal
    - Lethargy, easy fatigability, or lack of energy
    - Appetite change, overeating, food cravings
    - Hypersomnia or insomnia
    - Feeling out of control or overwhelmed
    - Subjective difficulty concentrating
    - Physical symptoms, such as abdominal bloating, breast tenderness, headaches, weight gain, and joint/muscle pain
  - For PMDD, emotional symptoms must be sufficiently severe to interfere with work, school, usual social activities, or relationships with others.
  - Symptoms may be superimposed on an underlying psychiatric disorder but may not be an exacerbation of another condition, such as panic disorder/major depression.
  - Criteria should be confirmed by prospective patient record of symptoms for a minimum of two consecutive menstrual cycles (without confirmation, “provisional” should be noted with diagnosis).
  - Use the Daily Record of Severity of Problems (available online at http://www.aafp.org/afp/2011/1015/p918-fig1.pdf) or similar inventory (1)[C].
  - Symptoms should not be attributable to drug abuse, medications, or other medical conditions.

PHYSICAL EXAM

No specific physical exam required; may consider thyroid and pelvic exams if indicated by additional patient symptoms

DIFFERENTIAL DIAGNOSIS

- Premenstrual exacerbation of underlying psychiatric disorder
- Psychiatric disorders (especially bipolar disorder, major depression, anxiety)
- Thyroid disorders
- Perimenopause
- Premenstrual migraine
- Chronic fatigue syndrome
- Irritable bowel syndrome (painful symptoms)
- Seizures
- Anemia
- Endometriosis (painful symptoms)
- Drug/alcohol abuse
DIAGNOSTIC TESTS & INTERPRETATION
- The repetitive nature of symptoms precludes need for labs if a classic history is present.
- Consider
  - Hemoglobin to rule out anemia
  - Serum thyroid-stimulating hormone (TSH) to rule out hypothyroidism
- Imaging with pelvic ultrasound to diagnose causes of pelvic pain and dysmenorrhea may be needed.

TREATMENT

GENERAL MEASURES
Although evidence is lacking for aerobic exercise in treating PMS/PMDD, it is often recommended as part of an integrated care plan.

MEDICATION

First Line
- SSRIs show a small to moderate effect in the treatment of physical, functional, and behavioral symptoms of PMS and PMDD compared to placebo (2)[A]:
  - Both intermittent luteal phase dosing and continuous full-cycle dosing are effective with no clear evidence of difference between modes of administration (2)[A].
  - All SSRIs tested appeared effective (2)[A].
  - SSRIs are effective at low doses. Higher doses have increased effect but are accompanied by increased side effects (2)[A].
- Fluoxetine (Prozac, Sarafem) 20 mg/day every day or 20 mg/day only during luteal phase, or 90 mg once a week for 2 weeks in luteal phase
- Sertraline (Zoloft) 50 to 150 mg/day every day or 50 to 150 mg/day only during luteal phase
- Citalopram (Celexa) 10 to 30 mg/day every day or 10 to 30 mg/day only during luteal phase
- Adverse effects (number needed to harm [NNH] with moderate-dose SSRI): nausea (NNH = 7), asthenia (NNH = 9), somnolence (NNH = 13), fatigue (NNH = 14), decreased libido (NNH = 14), and sweating (NNH = 14) (2)[A]
- Contraindications: patients taking monoamine oxidase inhibitors (MAOIs)
  - Precautions
    - Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders; uncertain if this risk applies to those taking SSRIs for PMDD
    - Bipolar disorder
    - Seizure disorder
    - QTc prolongation (with citalopram)
    - Hepatic dysfunction
    - Renal dysfunction
  - Possible interactions
    - MAOIs
    - Selegiline
    - Pimozide
    - Thoridazine
    - Cimetidine, omeprazole, and QTc-prolonging agents (with citalopram)
Second Line
Alternative therapies should be considered if no response to SSRIs:
- Spironolactone (Aldactone) 50 to 100 mg/day for 7 to 10 days during luteal phase; helpful for fluid retention; adverse reactions: lethargy, headache, irregular menses, hyperkalemia
- Oral contraceptive pills (OCPs)
  - OCPs can cause adverse effects similar to PMDD symptoms (3)[B].
  - Extended-cycle use of OCPs (e.g., 12 weeks on and 1 week off) or a shorter placebo interval (e.g., 24 active pills with 4 placebo days [24/4] compared with 21/7 preparations) may be beneficial (3)[B].
  - OCPs containing the progestin drospirenone (structurally similar to spironolactone) may improve physical symptoms and mood changes associated with PMDD (4)[A]. Caution: Risk of venous thromboembolism may be modestly higher than with other OCPs (3)[B].
  - Continuous administration of levonorgestrel/ethinyl estradiol may improve patient symptoms in PMDD (3)[B].
    - Suggested OCP formulations:
      - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg
        - (Gianvi/Loryna/Nikki/Ocella/Syeda/Vestura/Yasmin/Yaz Zarah): 1 tablet/day
      - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg/levomefolate 0.451 mg
        - (Beyaz/Safyral): 1 tablet/day
      - Levonorgestrel 90 μg/ethinyl estradiol 20 μg (Amethyst/Lybrel): 1 tablet/day
- Anxiolytics
  - Alprazolam (Xanax) 0.25 mg TID–QID only during luteal phase; taper at onset of menses (other benzodiazepines not studied for PMDD). Caution: addictive potential
  - Buspirone (Buspar) 10 to 30 mg/day divided BID–TID in the luteal phase
- Ovulation inhibitors
  - Gonadotropin-releasing hormone (GnRH) agonists: leuprolide (Lupron) depot 3.75 mg/month IM
    - Precautions: Menopause-like side effects (e.g., osteoporosis, hot flashes, headaches, muscle aches, vaginal dryness, irritability) limit treatment to 6 months; may be first step if considering bilateral oophorectomy for severe, refractory PMDD
  - Danazol (Danocrine) 300 to 400 mg BID; adverse reactions: androgenic and antiestrogenic effects (e.g., amenorrhea, weight gain, acne, fluid retention, hirsutism, hot flashes, vaginal dryness, emotional lability)
  - Estrogen, transdermal preferred, 100 to 200 μg:
    - Precautions: increased risk of blood clot, stroke, heart attack, and breast cancer
    - Requires concomitant progesterone add-back therapy to protect against uterine hyperplasia and endometrial cancer
- Progesterone: insufficient evidence to support use (5)[A]

ISSUES FOR REFERRAL
Referral to psychiatrist may be indicated for mood/anxiety disorders if patient has no symptom-free period.

ADDITIONAL THERAPIES
Cognitive-behavioral therapy (CBT) is theoretically helpful for PMS/PMDD given its application for symptom reduction in other mood disorders, but direct evidence is lacking.
SURGERY/OTHER PROCEDURES
Bilateral oophorectomy, usually with concomitant hysterectomy, is an option for rare, refractory cases with severe, disabling symptoms.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture demonstrated superiority to progestins, anxiolytics, and sham acupuncture with no evidence of harm (6)[A].

- Some data support the use of the following (7)[A]:
  - Calcium: 600 mg BID
  - Vitamin B₆: 50 to 100 mg/day
  - Chasteberry (Vitex agnus-castus): 4 mg/day of extract containing 6% of agnuside (or 20 to 40 mg/day of fruit extract)
  - Omega-3 fatty acids 2 g/day

- Data insufficient regarding the following (7)[A]:
  - Magnesium: 200 to 400 mg/day
  - Vitamin D: 2,000 IU/day
  - Vitamin E: 400 IU/day
  - Manganese: 1.8 mg/day
  - St. John’s wort: 900 mg/day
  - Ginkgo: 160 to 320 mg/day
  - Saffron: 30 mg/day

- Evidence supporting efficacy and/or safety of herbal products is lacking; the following products/interventions have not been found useful for PMS/PMDD, although not all studies are of high quality and able to eliminate possibility of benefit completely (7)[A]:
  - Evening primrose oil
  - Black currant oil
  - Black cohosh
  - Wild yam root
  - Dong quai
  - Kava kava
  - Light-based therapy

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders on initiation of SSRIs; uncertain if this risk applies to those taking SSRIs for PMDD

DIET
- Reduce consumption of salt, sugar, caffeine, dairy products, and alcohol (anecdotal reports).
- Eat small, frequent portions of food high in complex carbohydrates (limited data).

PATIENT EDUCATION
- Counsel patients to eat a balanced diet rich in calcium, vitamin D, and omega-3 fatty acids and
low in saturated fat and caffeine.
• Counsel women that they are not “crazy.” PMDD is a real disorder with a physiologic basis.
• Although incompletely understood, successful treatment is often possible.

PROGNOSIS
• Many patients can have their symptoms adequately controlled. PMS disappears at menopause.
• PMS can continue after hysterectomy, if ovaries are left in place.

REFERENCES

ADDITIONAL READING

CODES

ICD10
N94.3 Premenstrual tension syndrome

CLINICAL PEARLS
• Have the patient keep a daily log of her symptoms and menses. Symptoms beginning in the
week before menses and abating before the end of menses, occurring over at least 2 months, and sufficiently severe to interfere with daily functioning are diagnostic of PMS.

- The difference between PMS and PMDD is that PMDD is a severe form of PMS characterized by recurrent depressive and anxiety symptoms with luteal phase onset, sufficiently severe to disrupt social and occupational functioning. These symptoms remit a few days after the onset of menses.

- PMDD is not the same as more generalized depressive/anxiety disorders. PMDD-associated symptoms of depression and anxiety begin to resolve within the first few days of menses.

- Treatment only during the luteal phase is likely as effective as continuous-cycle treatment with SSRIs but has fewer adverse effects.
PRENATAL CARE AND TESTING
Anna K. Zheng, MD ● Henry Del Rosario, MD

BASICS
The goal of prenatal care is to ensure the well-being of mother and baby using the best available evidence guided by patient-oriented outcomes. General concepts include:
- Estimating the gestational age (GA) as accurately as possible
- Identifying the patient who is at risk for complications
- Evaluating the health status of mother and fetus
- Encouraging and empowering the patient for motherhood, newborn care, and breastfeeding her baby-to-be
- Intervening when fetal abnormalities are present to prevent morbidity

GENERAL PREVENTION
In the United States, the typical prenatal visit schedule consists of the following:
- Monthly visits to a health care professional for weeks 4 to 28 of pregnancy
- Visits twice monthly from 28 to 36 weeks
- Weekly after week 36 (delivery at weeks 38 to 40)

DIAGNOSIS
HISTORY
Collect the following histories in the initial prenatal visit and continually update throughout the pregnancy:
- Medical history, with an emphasis on the following:
  - Glucose intolerance, diabetes, obesity
  - Thyroid disorders
  - Pregestational hypertension
  - Maternal age at delivery
- Obstetrical history, including but not limited to:
  - History of preterm delivery and intrapartum problems
  - History of hypertensive disease (i.e., preeclampsia)
  - History of gestational diabetes
- Psychosocial history, including but not limited to:
  - Depression screening (use EPDS or PHQ9)
  - Intimate partner violence (ACOG guidelines recommend that physicians screen all pregnant patients for intimate partner domestic violence at the first prenatal visit, at least once per trimester, and at the postpartum checkup)
  - Tobacco, alcohol, and drug use
  - Lifestyle, nutrition, toxin exposures, travel to areas with endemic diseases, stressors/supports; potential barriers to care (communication and language, housing, transportation, child care issues, economic constraints, work schedule)

PHYSICAL EXAM
A full physical exam should be performed at the first prenatal appointment.

At each subsequent prenatal visit, the following should be recorded:

- **Weight** (2009 IOM recommendations)
  - BMI <18.5 kg/m² (underweight)—Weight gain 28 to 40 lb (12.5 to 18.0 kg)
  - BMI 18.5 to 24.9 kg/m² (normal weight)—Weight gain 25 to 35 lb (11.5 to 16.0 kg)
  - BMI 25.0 to 29.9 kg/m² (overweight)—Weight gain 15 to 25 lb (7.0 to 11.5 kg)
  - BMI ≥30.0 kg/m² (obese)—Weight gain 11 to 20 lb (5 to 9.0 kg)

- **BP**
  - ACOG defines hypertension as BP >140 mm Hg systolic or >90 mm Hg diastolic
  - Monitor BP, especially closely in patients with chronic hypertension (predating pregnancy), preeclampsia/eclampsia, or gestational hypertension

- **Fundal height**: beginning after 20 weeks and plotted
- **Fetal heart rate**
  - Usually audible by 12 weeks’ GA with a Doppler instrument
  - Effect on outcomes is not clear.
- **Pelvic/cervical exam if indicated**
  - Fetal position by abdominal palpation (Leopold’s maneuver) at 36 weeks

### DIAGNOSTIC TESTS & INTERPRETATION

- **First prenatal visit**:
  - **Lab tests**
    - Hematocrit or hemoglobin
    - Blood type: A, B, AB, or O
    - Rhesus type and antibody screen: Rh(+) or Rh(−)
    - Hemoglobin electrophoresis for patients at risk for sickle cell disease or thalassemia
    - Urine culture (by 16 weeks)
    - Rubella titer
    - Syphilis test
    - Gonorrhea/chlamydia screening
    - Hepatitis B surface antigen
    - HIV testing
    - Routine screening for bacterial vaginosis, toxoplasmosis, CMV, and parvovirus not recommended
    - Routine screening for thyroid and vitamin D deficiency during pregnancy is not recommended
  - **Carrier screening** (including, but not limited to):
    - Cystic fibrosis screening: Information should be made available to all couples and screening should be offered before conception or early in pregnancy when one partner is of Caucasian, European, or Ashkenazi Jewish descent.
    - Spinal muscular atrophy
    - Hemoglobinopathies (i.e., patients with risk factors for sickle cell disease, thalassemia)
  - **Screening for fetal aneuploidy**:
    - No one screening test is superior to other screening tests.
    - The risk of aneuploidy as well as the benefits, risks, and limitations of available screening tests should be discussed with the patient.
    - All women should be offered screening or diagnostic testing, regardless of maternal age
o Ultrasound (US) nuchal translucency (NT): measures thickness at the back of the neck of the fetus
o Blood screens: human chorionic gonadotropin (hCG), pregnancy-associated plasma protein A (PAPP-A), quadruple test: α-fetoprotein (AFP), unconjugated estriol (UE3), hCG, dimeric inhibin-A (DIA)

- 1st-trimester “combined test” between 11 and 13 weeks’ GA using both NT and hCG/PAPPA blood testing is an effective protocol; may be performed either as a single combined stand-alone test (US NT 1 blood [HCG and PAPP-A]) or as part of a sequential “step-by-step” 1st- and 2nd-trimester screening process (see the following discussion)

- Women who undergo 1st-trimester screening should be offered 2nd-trimester assessment for open fetal defects and US screening for other fetal structural defects. (1)[C].

- 2nd-trimester screening protocols
  - Obtain quadruple test ideally at 15 to 18 weeks’ GA but can be done as late as 22 weeks.
  - Integrated screening tests: combine information collected during the 1st and 2nd trimesters of the pregnancy to determine the risk of Down syndrome, trisomy 18, or open NTD:
    - Three options:
      - Full integrated test: serum PAPP-A at 10 to 13 weeks and sonographic NT at 11 to 13 weeks as first step; results are integrated with results of quadruple test performed at 15 to 18 weeks.
      - Serum integrated test: differs from full integrated test by not including US measurement of NT
      - Step-wise sequential testing: Perform 1st trimester portion of full integrated test, reporting risks of Down syndrome to the patient and offering chorionic villus sampling (CVS) to women whose results place them at very high risk (≥1:50); if screen does not place woman at very high risk, then perform 2nd trimester portion of test.
  - Diagnostic tests for genetic disorders:
    - ACOG guidelines: All pregnant women should be offered invasive prenatal diagnostic testing, such as CVS and amniocentesis, regardless of maternal age or other risk factors. (2)[C].
    - Women found to be at increased risk of having a baby with a genetic disorder should be offered genetic counseling and the option of CVS or midtrimester amniocentesis.

There are two possible diagnostic tests:
- CVS: 1st trimester: usually done after 10 weeks (10 to 12 weeks). Small sample of the placenta; chorionic tissue sample obtained either transcervical (TC) or transabdominal (TA)
- Amniocentesis
  - Not recommended before 14 weeks’ gestation (2)[C]
  - Usually done after 15 weeks (15 to 18 weeks). Small sample of amniotic fluid from the amniotic sac surrounding the developing fetus is obtained by an US-
guiding TA approach.

- The rate of procedure-related pregnancy loss that is attributable to a prenatal diagnostic procedure is 0.1–0.3% when performed by experienced health care providers (2)[B].

- Chromosomal microarray analysis: can detect a pathogenic copy number variant in about 1.7% of patients with normal US and normal karyotype; should be made available to any patient choosing to undergo invasive diagnostic testing; should be primary test for patients undergoing diagnostic testing for indication of a fetal structural abnormality detected by US examination (2)[C]

- Cervical cancer screening:
  - A Pap smear should be obtained when indicated by standard Pap screening guidelines, regardless of gestation (ACOG, USPSTF, ASCCP, ACS, and ASCP guidelines state that women <21 years should not be screened regardless of age of sexual initiation or other risk factors).
  - Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
  - LSIL in pregnancy: colposcopy preferred, but it is acceptable to defer colposcopy to 6 weeks postpartum
  - CIN 1 in pregnancy: Follow-up without treatment is recommended.
  - CIN 2, CIN 3, or CIN 2,3 in pregnancy: In the absence of invasive disease or advanced pregnancy, additional colposcopic and cytologic examinations are acceptable; repeat biopsy is recommended only if appearance of lesion worsens or if cytology suggests invasive cancer; it is acceptable to defer reevaluation until 6 weeks postpartum.
  - Endocervical sampling is contraindicated.

Subsequent prenatal visits:
- Urinalysis for glucose and protein
  - Although evidence for the benefits and harms are limited
  - Baseline during initial intake may be useful for high-risk patients

24 to 28 week prenatal visits:
- Obtain diabetes screen.
- See the following discussion: Repeat hematocrit or hemoglobin, and repeat antibody screen in Rh-negative mother prior to receiving prophylactic Rh immunoglobulin.
  - Gestational diabetes mellitus (GDM) screening
  - The ADA and ACOG define women at increased risk of overt diabetes who need earlier screening based on body mass index (BMI): ≥25 kg/m² (≥23 kg/m² in Asian Americans) plus one or more of the following:
    - Physical inactivity
    - Previous pregnancy history of:
      - GDM
      - Macrosomia (≥4,000 g)
      - Stillbirth
    - Hypertension (140/90 mm Hg or being treated for hypertension)
    - HDL cholesterol ≤35 mg/dL (0.90 mmol/L)
    - Fasting triglyceride ≥250 mg/dL (2.82 mmol/L)
    - Hemoglobin A1C ≥5.7%, impaired glucose tolerance or impaired fasting glucose
    - PCOS, acanthosis nigricans, nonalcoholic steatohepatitis, morbid obesity, and other
conditions associated with insulin resistance

- Cardiovascular disease
- Family history of diabetes—first-degree relative (parent or sibling)
- Ethnicity of African American, American Indian, Asian American, Hispanic, Latina, or Pacific Islander

- Gestational diabetes: fasting plasma glucose >92 mg/dL but is <126 mg/dL at any GA. At 24 to 28 weeks’ GA, a 75-g 2-hour oral glucose tolerance test (OGTT) with at least one abnormal result: FBG ≥92 mg/dL, but <126 mg/dL or 1 hour ≥180 mg/dL, or 2-hour ≥153 mg/dL

- The following guidelines for GDM are established by ACOG:
  - Specified cutoffs define GDM.
    - A value of >130 mg/dL will identify 90% of women with GDM, but 20–25% of all women screened will need to continue to the 3-hour OGTT.
    - Raising the value to >140 mg/dL will identify only 80% of women with GDM but decrease to 14–18% the number of women who will need to continue to the 3-hour OGTT.
  - Screening test: 1-hour OGTT (nonfasting)
    - 50 g PO glucose load with blood glucose testing 1 hour later
    - Carpenter and Coustan positive screen: >130 mg/dL
    - National Diabetes Data Group (NDDG) positive screen: >140 mg/dL
  - Diagnostic test: 3-hour OGTT (fasting)
    - If abnormal 1-hour OGTT screening test, may be followed by a 3-hour OGTT
    - 100 g PO glucose load with blood drawn: fasting, 1, 2, and 3 hours after ingestion of glucose
    - Either the plasma or serum glucose level designated by Carpenter and Coustan or by the NDDG is appropriate to use:
      - *A positive diagnosis of GDM requires that ≥2 thresholds be exceeded.
        - Carpenter and Coustan standard: *>95 (fasting), >180 (1-hour), >155 (2-hour), >140 (3-hour)
        - NDDG standard: *105 (fasting), >190 (1-hour), >165 (2-hour), >145 (3-hour)
  - ACOG (based on NIH consensus panel findings) still supports the “2-step” approach (24- to 28-week 1-hour venous glucose measurement following 50 g oral glucose solution), followed by a 3-hour OGTT if positive.
  - Although the diagnosis of GDM is based on two abnormal values on the 3-hour OGTT, ACOG states, due to known adverse events, one abnormal value may be sufficient to make the diagnosis.
  - 1-step approach (75-g OGTT) on all women will increase the diagnosis of GDM, but sufficient prospective studies demonstrating improved outcomes still lacking.
  - ACOG does acknowledge that some centers may opt for “1 step” if warranted based on their population.

- 35 to 37 week prenatal visits:
  - Group B Streptococcus (GBS) culture: Screen all women at 35 to 37 weeks’ GA to identify women colonized with GBS.
  - High-risk patients: should be screened again for gonorrhea, chlamydia, HIV, and syphilis.

- Postterm pregnancy:
  - Rate of stillbirth increases with GA by 1/3,000 per week at 37 weeks, 3/3,000 per week at
42 weeks, and 6/3,000 at 43 weeks. In one meta-analysis, routine induction of labor at 41 weeks’ GA reduced rates of perinatal death without increased rates of cesarean delivery. There is some evidence for benefit for induction of labor at 39 weeks’ GA.

- For gestational periods beyond 42 weeks, fetal well-being should be assessed with nonstress testing and US assessment of amniotic fluid volume.

**TREATMENT**

**ISSUES FOR REFERRAL**

Abnormal screening labs or imaging may prompt referral to maternal–fetal medicine specialist or other medical specialist, as indicated.

**ONGOING CARE**

**PATIENT EDUCATION**

- Immunizations during pregnancy per CDC:
  - Women should get Tdap during each pregnancy (should be given between 27 to 36 weeks’ GA); hepatitis B and influenza are safe; likely safe include meningococcal, rabies. Contraindicated during pregnancy or safety not established: live vaccines including BCG, MMR, and varicella
  - Recommendations for use of dietary supplements in pregnancy
    - Folic acid 0.4 mg daily beginning at least 1 month prior to attempting conception and continuing throughout pregnancy; 1 to 4 mg for women at higher risk of having child with neural tube defect beginning 1 to 3 months before conception, continued through first 12 weeks’ GA, and then reduced to 0.4 mg daily
    - Calcium: 1,000 to 1,300 mg/day; supplement may be beneficial for women with high risk for gestational hypertension or communities with low dietary calcium intake.
    - Caffeine: Limit to <200 mg/day. Correlation between IUGR and miscarriage with caffeine is undetermined at this time.
    - Iron: Screen for anemia (hemoglobin/hematocrit) and treat if necessary.
    - Vitamin A: Pregnant women in industrialized countries should limit to <5,000 IU/day.
    - Vitamin D: 200 to 1,200 IU (dose in standard prenatal vitamin) is recommended until more evidence is available to support different dose.
  - Airline travel: generally safe until up to 4 weeks from EDD; lengthy trips associated with increased risk of thrombosis
  - Exercise: Healthy women with uncomplicated pregnancies should continue to exercise.
  - Seat belts/air bags: ACOG recommends that pregnant women wear lap and shoulder seatbelts and should not turn off air bags.
  - Sexual activity: Intercourse is not associated with adverse outcomes.
  - Alcohol, cigarettes, and illicit drugs are injurious to fetal and maternal health.
  - Pregnancy-safe medications (teratogenicity)
  - Preconception counseling offers the opportunity to discuss individualized risks.

**REFERENCES**

**CODES**

**ICD10**
- Z34.90 Encntr for suprvsn of normal pregnancy, unsp, unsp trimester
- Z36 Encounter for antenatal screening of mother

**CLINICAL PEARLS**

Prenatal care and screening are best accomplished using standardized flow sheets and checklists to ensure that the complex sequence of evaluations and education is performed consistently and properly.
PREOPERATIVE EVALUATION OF THE NONCARDIAC SURGICAL PATIENT
Andrew E. Grimes, MD ● Stacy L. Jones, MD, FASA

BASICS

DESCRIPTION
- Preoperative medical evaluation should determine the presence of established or unrecognized disease or other factors that may increase the risk of perioperative morbidity and mortality in patients undergoing surgery.
- Specific assessment goals include the following:
  - Conducting a thorough medical history and physical exam to assess the need for further testing and/or consultation
  - Recommending strategies to reduce risk and optimize patient condition prior to surgery
  - Encouraging patients to optimize their health for possible improvement of both perioperative and long-term outcomes
- Synonym(s): preoperative diagnostic workup; preoperative preparation; preoperative general health assessment

EPIDEMIOLOGY
Overall patient morbidity and mortality related to surgery is low. One large study of inpatients looking at 30-day mortality in the United States showed a rate of 1.32%. This rate varies by type of procedure and varies by country. Preoperative patient evaluation and subsequent optimization of perioperative care can reduce both postoperative morbidity and mortality.

RISK FACTORS
- Functional capacity (1): Exercise tolerance is one of the most important determinants of cardiac risk:
  - Self-reported exercise tolerance may be an extremely useful predictive tool when assessing risk. Patients unable to meet a 4–metabolic equivalents (METs) demand (defined in the “Diagnosis” section) during daily activities have increased perioperative cardiac and long-term risks. A study compared physicians’ subjective assessment of functional capacity to objective measures of functional capacity. It found that the subjective assessment tended to misclassify high-risk patients as low risk. Structured questionnaires such as the Duke Activity Status Index had much better prognostic accuracy to assess functional status (2).
  - Patients who report good exercise tolerance require minimal, if any, additional testing.
- Levels of surgical risk
  - An increased risk for major adverse cardiac events (MACE) is associated with procedures that are intrathoracic, intra-abdominal, or vascular procedures that are suprainguinal in nature (1).
- Clinical risk factors (1): history of ischemic heart disease, the presence of compensated heart failure or a history of prior congestive heart failure (CHF), cerebrovascular disease, diabetes mellitus (DM), and renal insufficiency; these risk factors plus surgical risk can dictate the need for further cardiac testing.
- Age: Patients >70 years of age are at higher risk for perioperative complications and mortality
and have a longer length of stay in the hospital postoperatively (likely attributed to increasing medical comorbidities with increasing age). Age alone should not be a deciding factor in the decision to proceed or not to proceed with surgery.

**DIAGNOSIS**

**HISTORY**

- Evaluate pertinent medical records and interview the patient. Many institutions provide standard patient questionnaires that screen for preoperative risk factors:
  - History of present illness and treatments
  - Past medical and surgical history
  - Patient and family anesthetic history and associated complications
  - Current medications (including over-the-counter [OTC] medications, vitamins, supplements, and herbal) as well as reasons for use
  - Allergies (including specific reactions)
  - Social history: tobacco, alcohol, drug use, and cessation
  - Family history: prior illnesses and surgeries
- Systems (both history and current status)
  - Cardiovascular: Inquire about exercise capacity.
    - 1 MET: can take care of self, eat, dress, and use toilet; walk around house indoors; walk a block or two on level ground at 2 to 3 mph
    - 4 METs: can climb flight of stairs or walk uphill, walk on level ground at 4 mph, run a short distance, do heavy work around house, participate in moderate recreational activities
    - 10 METs: can participate in strenuous sports such as swimming, singles tennis, football, basketball, or skiing
  - Note presence of CHF, cardiomyopathy, ischemic heart disease (stable vs. unstable), valvular disease, hypertension (HTN), arrhythmias, murmurs, pericarditis, history of pacemaker or implantable cardioverter defibrillator (ICD):
    - Rhythm management devices (pacemakers and automatic ICDs [AICDs]) affect the perioperative course. Most importantly, the following information needs to be available for proper management: name of cardiologist who manages the device, type of device, manufacturer, last interrogation, and any problems that have occurred recently. Based on this information and the location and type of surgery, a perioperative plan of management will be made.
    - Stents: Patients with coronary stents are maintained on duel antiplatelet therapy (DAPT) for a prescribed period of time. This is typically done with a thienopyridine, such as clopidogrel, in combination with aspirin. The perioperative period is associated with a prothrombotic state. Premature discontinuation of DAPT markedly increases the risk of acute stent thrombosis, myocardial infarction (MI), and death. Elective surgery should be delayed and DAPT continued for a minimum of 30 days after bare metal stent placement. Duration of dual antiplatelet therapy following drug-eluting stent (DES) placement depends upon the type of stent and risk of thrombosis. DAPT has been advised for 6–12 months following DES, but shorter durations may be possible for newer stents (3). Several caveats to these recommendations exist. Extending the time for DAPT after stent placement is indicated in certain scenarios such as stent placement in the setting of an
acute cardiac syndrome. Any perioperative disruption in the patient’s DAPT regimen needs to be discussed with the patient’s cardiologist and surgeon. The risk of perioperative bleeding must be weighed against the risks of discontinuation of DAPT prior to surgery (4).

– Pulmonary: Chronic and active disease processes should be addressed: chronic infections, bronchitis, emphysema, asthma, wheezing, shortness of breath, cough (productive or otherwise):
  o Sleep apnea: Patients with obstructive sleep apnea (OSA) are at increased risk for perioperative adverse events. Screening tools (such as the STOP-Bang) can help risk stratify patients. Additional evaluation should be considered if a patient has associated significant systemic disease, hypoventilation syndrome, severe pulmonary HTN, or resting hypoxemia.
  o Often, patients with an existing diagnosis of OSA who use positive airway pressure (PAP) at night are asked to bring their PAP machine to the hospital or surgery center when they are admitted for surgery. For patients with suspected but previously undiagnosed OSA, PAP therapy should be considered on a case-by-case basis.
  o Some studies suggest that even short periods (3 weeks) of treatment with PAP can improve some indices of ventilation and therefore may reduce postoperative morbidity.
– GI: hepatic disease, gastric ulcer, inflammatory bowel disease, hemias (especially hiatal), significant weight loss, nausea, vomiting, history of postoperative nausea, and vomiting: Any symptoms consistent with gastroesophageal reflux disease (GERD) should be optimally treated.
– Hematologic: anemia, serious bleeding, clotting problems, blood transfusions, hereditary disorders
– Renal: kidney failure, dialysis, infections, stones, changes in bladder function
– Endocrine: nocturia, parathyroid, pituitary, adrenal disease, thyroid disease
  o Diabetes: Evidence that hyperglycemia in the perioperative period is associated with increased perioperative complications. Although recommendations vary, most experts recommend keeping perioperative blood glucose levels <180 mg/dl.
– Neurologic/psychiatric: seizures, stroke, paralysis, tremor, migraine headaches, nerve injury, multiple sclerosis, extremity numbness, psychiatric disorders (e.g., anxiety, depression)
– Musculoskeletal: arthritis, lower back pain
– Frailty is increasingly recognized as a perioperative risk factor. Research is being done on various screening tools and interventions that can decrease perioperative mortality and morbidity in the frail population.
– Reproductive: possibility of pregnancy in women of childbearing potential

● Mouth/upper airway: dentures, crowns, partials, bridges, teeth (loose, chipped, cracked, capped)

**PHYSICAL EXAM**

● Assess vital signs, including arterial BP bilaterally.
● Check carotid pulses; auscultate for bruits.
● Examine lungs by auscultating all lung fields and listening for rales, rhonchi, wheezes, or other sounds indicating disease.
● Examine cardiovascular system by auscultating heart and noting any irregular rhythms or murmurs; precordial palpation
Palpate abdomen.
Examine airway and mouth for ease of intubation, neck mobility, and size of tongue; note any lesions or dental deformities.
If a regional anesthesia technique is being contemplated, perform a relevant, focused neurologic exam.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Laboratory testing should never be “routine” prior to surgery. Tests should be obtained only when indicated by specific conditions or risk factors ([5][C]). “Routine” testing results in unnecessary delays and disruptions to planned surgery. Specific tests should be requested if the evaluator suspects findings from the clinical evaluation that may influence perioperative patient management.
- Labs performed within the past 4 months prior to evaluation are reliable, unless the patient has had an interim change in clinical presentation or is taking medications that require monitoring of plasma level or effect.
- **CBC ([5][C])**
  - Hemoglobin: if a patient has symptoms of anemia or is undergoing a procedure with major blood loss; extremes of age; liver or kidney disease
  - WBC count: if symptoms suggest infection or myeloproliferative disorder or the patient is at risk for chemotherapy-induced leukopenia
  - Platelet count: if history of bleeding, myeloproliferative disorder, liver or renal disease, or the patient is at risk for chemotherapy-induced thrombocytopenia
- Serum chemistries (electrolytes, glucose, renal and liver function tests): should be obtained for extremes of age; in known renal insufficiency, CHF, liver dysfunction, or endocrine abnormalities; or the patient is on medications that alter electrolyte levels, such as diuretics
- PT/PTT: if history of a bleeding disorder, chronic liver disease, or malnutrition, or those with recent or chronic antibiotic or anticoagulant use
- Urinalysis: Routine urinalysis is not recommended preoperatively.
- Pregnancy test: controversial; should be considered for all female patients of childbearing age
- CXR is not generally indicated. It can be considered in patients with recent upper respiratory tract infection and in those with suspected cardiac or pulmonary disease (because there is a likelihood for unanticipated findings), but these indications are not considered unequivocal.

**Diagnostic Procedures/Other**
- **ECG ([1][C])**
  - Preoperative resting 12-lead ECG is reasonable for patients with known coronary disease, known peripheral vascular disease, significant arrhythmia, or known significant structural heart disease.
  - ECGs are not indicated for asymptomatic patients undergoing low-risk procedures.
- The American Heart Association (AHA) guidelines recommend using the Revised Cardiac Risk Index or the ACS NSQIP online risk calculator to make an estimate of risk of MACE in the perioperative period. If the risk of MACE is low (<1%), then proceed with surgery. If the risk is >1%, the functional capacity needs to be considered. For patients with a functional capacity of >4 METs, then proceed with surgery. If the functional capacity is <4 METs or unknown, consider pharmacologic stress testing if it will change management ([1]).
- PFTs: Definitive data regarding the efficacy of preoperative testing are lacking. The most
important factor is preoperative optimization of patients with chronic obstructive pulmonary disease (COPD) or reactive airways disease with indicated use of antibiotics, bronchodilators, and inhaled corticosteroids. Spirometry can help guide therapy. Upper abdominal and thoracic surgery has a higher risk of postoperative pulmonary complications.

**TREATMENT**

**MEDICATION**

- **Reducing cardiac risk**
  - Elective surgery should be delayed or cancelled if the patient has any of the following: unstable coronary syndromes (unstable or severe angina), recent MI (<30 days), decompensated heart failure, significant arrhythmias, or severe valvular disease.
  - Timing of elective noncardiac surgery after ischemic stroke or myocardial infarction can have a significant effect on perioperative morbidity and mortality. The AHA/ACC guidelines recommend waiting at least 60 days after a myocardial infarction if the patient did not require a coronary intervention. There is a significant increase in both risk of MACE and mortality associated with elective surgery within 3 months of an ischemic stroke (6).
  - Active HF should be treated with diuretics, afterload reduction, and β-adrenergic blockers.
  - Perioperative β-blockade has been shown to reduce mortality and the incidence of perioperative MIs in high-risk patients. Studies conflict, however, in which patients need to be treated, the dosage and timing of treatment, and for what surgeries. Patients chronically on β-blockers should have the medication continued in the perioperative period. When β-blockers are discontinued in the perioperative period, 30-day mortality increases. β-Blockers are reasonable for vascular surgery patients with at least one clinical risk factor. It is not recommended to start β-blockers on the day of surgery in β-blocker–naive patients (1).
  - Perioperative statin use may have a protective effect on reducing cardiac complications. Currently, the AHA has a class I indication for perioperative statin therapy for patients already on statins prior to their surgery. There is also evidence that vascular surgery patients benefit from perioperative statins.
  - A recent review examined prophylactic use of aspirin in the perioperative period and did not find a significant effect on perioperative mortality or risk for MI in patients undergoing noncardiac surgery and may be associated with an increased risk of perioperative bleeding. There were important exclusion criteria, including patients with recent stent placement.

- **Reducing pulmonary risk**
  - Recommend cigarette cessation for at least 8 weeks prior to elective surgery.
  - Patients with asthma should not be wheezing and should have a peak flow of at least 80% of their predicted or personal-best value.
  - Treatment of COPD and asthma should focus on maximally reducing airflow obstruction and is identical to treatment of nonsurgical patients.
  - Lower respiratory tract infections (bacterial) should be treated with appropriate antibiotic therapy.

Algorithm: Preoperative Evaluation of Noncardiac Surgical Patient

CODES

ICD10

- Z01.818 Encounter for other preprocedural examination
- Z01.811 Encounter for preprocedural respiratory examination
- Z01.812 Encounter for preprocedural laboratory examination

CLINICAL PEARLS
- The preoperative evaluation should include medical record evaluation, patient interview, and physical exam.
- The minimum for the physical exam includes airway, pulmonary, and cardiovascular exams.
- Functional capacity, the level of surgical risk, and clinical risk factors determine if further cardiac testing is needed.
- No preoperative tests are or should be routine.
- Active cardiac conditions should lead to delay or cancellation of nonemergent surgery.
BASICS
DESCRIPTION
- Presbycusis is an age-related hearing loss (HL) showing increased incidence with age. It often presents as difficulty communicating in noisy conditions.
- May be divided into central and peripheral causes:
  - Central presbycusis: age-related change in the auditory portions of the central nervous system negatively impacting auditory perception, speech-communication performance, or both
  - Peripheral presbycusis: age-related, bilateral sensorineural HL (SNHL) typically symmetric
- Represents a lifetime of insults to the auditory system from toxic noise exposure and natural decline
- Initially presents as high-frequency SNHL with tinnitus (ringing)
- Impacts the “clarity” of sounds (i.e., ability to detect, identify, and localize sounds)
- Due to mild and progressive nature, presbycusis is often treated with amplification alone.
- Can lead to adverse effects on physical, cognitive, emotional, behavioral, and social function in the elderly (e.g., depression, social isolation, and is a contributor to all-cause dementia) (1)

EPIDEMIOLOGY
Incidence
According to an ongoing community-based epidemiologic study, the 10-year cumulative incidence rates of HL are as follows, approximately:
- Age 48 to 59 years: M (31.7%), F (15.6%); all (21.8%)
- Age 60 to 69 years: M (56.8%), F (40.7%); all (45.5%)
- Age 70 to 79 years: M (87.1%), F (70.6%); all (73.7%)
- Age 80 to 92 years: M (100%), F (100%); all (100%)

Prevalence
- 10% of the population develops SNHL severe enough to impair communication.
- Increases to 40% in the population >65 years of age
- 80% of HL cases occur in elderly patients.
- Only 10–20% of older adults with HL have ever used hearing aids (HAs).
- Predominant sex: male > female
- Hearing levels are poorer in industrialized societies than in isolated or agrarian societies.

ETIOLOGY AND PATHOPHYSIOLOGY
- The external ear transmits sound energy to the tympanic membrane. The middle ear ossicles amplify and conduct the sound waves into the inner ear (cochlea) via the oval window. The organ of Corti, located in the cochlea, contains hair cells that detect these vibrations and depolarize, producing electrical signals that travel through the auditory nerve to the brain. Toxic noise exposure traumatizes the hair cells and leads to cell death and HL. New research also suggests that overexcitation of the neurosynapses causes increased glutamate, which is also neurotoxic (2).
– Sensory presbycusis: primary loss of the hair cells in the basal end of the cochlea (high-frequency HL)
– Neural presbycusis: loss of spiral ganglion cells (nerve cells induced by hair cells to produce action potentials to travel to the brainstem)
– Strial (metabolic) presbycusis: atrophy of the stria vascularis (the cochlear tissue that generates the endocochlear electrical potential)
– Cochlear conductive (mechanical) presbycusis: no morphologic findings (presumed stiffening of the basilar membrane)
– Mixed presbycusis: combinations of hair cell, ganglion cell, and stria vascularis loss
– Indeterminate presbycusis: no morphologic findings (presumed impaired cellular function)

Presbycusis is caused by the accumulated effects of noise exposure, systemic disease, oxidative damage, ototoxic drugs, and genetic susceptibility.

**Genetics**

Presbycusis has a clear familial aggregation:

– Heritability estimates show 35–55% of the variance of sensory presbycusis is from genetic factors; even greater percentage in strial presbycusis
– Heritability is stronger among women than men.

**RISK FACTORS**

– Noise exposure (military, industrial, etc.)
– Ototoxic substances
  – Organic solvents
  – Heavy metals
  – Carbon monoxide
– Drugs
  – Aminoglycosides
  – Cisplatin
  – Salicylates
  – Diuretics
– Tobacco smoking
– Alcohol
– Lower socioeconomic status
– Family history of presbycusis
– Head trauma (temporal bone fractures)
– Cardiovascular disease (hypertension, atherosclerosis, hyperlipidemia); labyrinthine artery is terminal artery to the cochlea.
– Diabetes mellitus
– Autoimmune disease (autocochleitis/labyrinthitis)
– Metabolic bone disease
– Endocrine medical conditions: levels of aldosterone
– Alzheimer disease
– Otologic conditions (e.g., Ménière disease or otosclerosis)

**GENERAL PREVENTION**

– Avoid hazardous noise exposure.
– Use hearing protection.
Maintain healthy diet and exercise.

Screening

- In the only published RCT on screening for HL, HA use was significantly higher in three screened groups (4.1% in those using a questionnaire, 6.3% using handheld audiometry, and 7.4% using both modalities) versus unscreened control participants (3.3%) at 1-year follow-up (3)[B].
- Based on a 2011 review, according to the USPSTF, there is insufficient evidence to assess the relative benefits and harms of HL screening in adults ≥50 years (4)[B].

**DIAGNOSIS**

**HISTORY**

- Reduced hearing sensitivity and speech understanding in noisy/public environments
- Impaired localization of sound sources
- Increased difficulty understanding conversations, especially with women, due to higher frequency of spoken voice
- Presents bilaterally and symmetrically
- If unilateral HL, alternative diagnosis should be pursued.

Additional history if HL is suspected or detected (5)[B]:

- Time course of HL
- Symptoms of tinnitus, otalgia, otorrhea, or vertigo
- History of noise exposure, ear trauma, or head trauma
- Presence of any neurologic deficit

Reports from patient/family/caregiver (5)[B]

- Confusion in social situations
- Excessive volume of television/radio/computer
- Social withdrawal
- Anxiety in group settings

**PHYSICAL EXAM**

- Rinne and Weber tests are helpful for determining conductive versus SNHL but not recommended for general screening.
- Pneumatic otoscopy to evaluate for simple middle-ear effusion as cause of conductive HL

**DIFFERENTIAL DIAGNOSIS**

- Complete canal occlusion (cerumen, foreign body)
- Large external ear tumors (e.g., polyp, exostosis, squamous cell)
- Otitis externa
- Chronic otitis media or effusion
- Cholesteatoma
- Otosclerosis
- Osteogenesis imperfecta
- Large middle-ear tumors (e.g., facial nerve schwannomas, paragangliomas)
- Perilymph fistula (trauma/iatrogenic)
- Ménière disease
- Acoustic neuroma (usually unilateral)
Vascular anomaly
Acute noise-induced traumatic loss (explosion)
Autoimmune HL

**DIAGNOSTIC TESTS & INTERPRETATION**
- Central: synthetic sentence identification test with ipsilateral competing message and the dichotic sentence identification test (6)[A]
- Peripheral: handheld audiometry; insert probe in ear (sealing canal) and have patient indicate if tones can be heard.
  - Positive likelihood ratio (LR) range, 3.1 to 5.8; negative LR range, 0.03 to 0.40
- Screening audiometry
  - Symmetric high-frequency HL in descending slope pattern
  - SNHL frequencies >2 KHz initially
  - Essential to determine global clinical hearing status and if etiology is conductive HL versus SNHL or pseudohypacusis (conversion)

**TREATMENT**
- HAs
  - Types
    - Analog HA: picks up sound waves through a microphone; converts them into electrical signals; amplifies and sends them through the ear canal to the tympanic membrane
    - Digital HA: programmable; may reduce acoustic feedback, reduce background noise, detect and automatically accommodate different listening environments, control multiple microphones
  - HAs have an average decibel gain of 16.3 dB.
  - Associated with hypersensitivity to loud sounds (“loudness recruitment”)
- Hearing-assistive technologies (HATs) (7)[A]
  - Can be used alone or in combination with HAs (for difficult listening conditions)
  - Addresses face-to-face communication, broadcast or other electronic media (radio, TV), telephone conversation, sensitivity to alerting signals and environment stimuli (doorbell, baby’s cry, alarm clock, etc.)
  - Includes personal FM systems, infrared systems, induction loop systems, hardwired systems, telephone amplifier, telecoil, TDD (telecommunication device for the deaf), situation-specific devices (e.g., television), alerting devices
- Aural rehabilitation (also known as audiologic orientation or auditory training) (5)[A]
  - Adjunct to HA or HATs
  - Involves education regarding proper use of amplification devices, coaching on how to manage the auditory environment, training in speech perception and communication, and counseling for coping strategies to deal with the difficulties of HAs or HATs

**ISSUES FOR REFERRAL**
Refer to audiologist for formal evaluation and optimal fitting of HAs and/or HATs.
- Individuals receiving postfitting orientation/education have significantly fewer HA returns.
- Individuals receiving >2 hours of education and counseling report higher levels of satisfaction.

**SURGERY/OTHER PROCEDURES**
Cochlear implants (CIs)
- Works by bypassing the ear canal, middle ear, and hair cells in the cochlea to provide electric stimulation directly to the auditory nerve
- Indications include hearing no better than identifying $\leq 50\%$ of key words in test sentences in the best aided condition in the worst ear and $60\%$ in the better ear.
- Incoming sounds are received through the microphone in the audio processor component (resembles a small HA), which converts them into electrical impulses and sends them to the magnetic coil (located on the skin). The impulses transmit these across intact skin via radio waves to the implanted component (directly subjacent to the coil). The pulses travel to the electrodes in the cochlea and stimulate the cochlea at high rates.
- Receiving a unilateral CI is most common; some may receive bilateral CIs (either sequentially or in the same surgery). Others may wear a CI in one ear and an HA in the contralateral ear (bimodal fit).
- Younger age at CI placement derives greatest benefit.

Active middle-ear implants (AMEIs)
- Suitable for elderly adults who cannot wear conventional HAs for medical or personal (cosmetic) reasons and whose HL is not severe enough for a CI
- Comes in different models and may include components that are implantable under the skin

Electric acoustic stimulation: use of CI and HA together in one ear
- Addresses the specific needs of patients presenting with good low-frequency hearing (a mild to moderate sensorineural HL in frequencies up to 1,000 Hz) but poorer hearing in the high frequencies (sloping to 60 dB or worse HL $>1,000$ Hz)
  - Contraindications: progressive HL, autoimmune disease; HL related to meningitis, otosclerosis, or ossification; malformation of the cochlea; a gap in air conduction and bone conduction thresholds of $>15$ dB; external ear contraindications, active infection, or unwillingness to use amplification devices

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- During follow-up visits, check for compliance of HA use as 25–40% of adults will either stop wearing them or use them only occasionally.
- Assess perceived benefit of HA and, if ineffective, for indications for possible surgical treatments.
- Annual audiograms
- Can follow up with audiologists for HA fittings if HA becomes uncomfortable
- Asymmetric HL should have evaluation via MRI for acoustic neuroma.
- Sudden SNHL is atypical and warrants urgent otolaryngologic evaluation/audiometry. The most recent recommendations by the American Academy of Otolaryngology recommend steroids empirically.

PATIENT EDUCATION
- Should be face-to-face; spoken clearly and unhurriedly, without competing background noise (e.g., radio, TV); and include a confirmation that the message is received
Formal-speech reading classes may be beneficial; however, availability may be limited.

ADDITIONAL READING

CODES

ICD10
- H91.10 Presbycusis, unspecified ear
- H91.13 Presbycusis, bilateral
- H91.11 Presbycusis, right ear

CLINICAL PEARLS

- Presbycusis is an age-related HL, showing increased incidence with age. It is often bilateral and initially begins as high-frequency HL. It presents as difficulty communicating in noisy conditions.
- Compliance is only 25–40% for those who own HA. A referral to an audiologist is key for optimal evaluation, fitting for HAs, and other assistive technologies or surgical treatment.
- Indication for CIs include hearing no better than identifying ≤50% key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
- Early audiology referral for individuals with suspected HL may improve treatment efficacy.
PRESSURE ULCER
Marzena Gieniusz, MD

BASICS
DESCRIPTION
- A localized area of skin or underlying tissue injury resulting from pressure and/or shear
- Classified in stages according to the National Pressure Ulcer Advisory Panel (NPUAP):
  - Stage I: nonblanchable erythema—intact skin with nonblanchable redness; darkly pigmented skin may not have visible blanching.
  - Stage II: partial thickness skin loss—shallow open ulcer with a red-pink wound bed, without slough; or intact or open/ruptured serum-filled blister
  - Stage III: full thickness skin loss—subcutaneous fat may be visible but bone, tendon, or muscle is not exposed; slough, if present, does not obscure depth of tissue loss.
  - Stage IV: full thickness tissue loss—exposed bone, tendon, or joint; slough or eschar may be present but does not completely obscure wound base.
  - Unstageable: depth unknown—base of the ulcer is covered by slough and/or eschar in the wound bed.
  - Suspected deep tissue injury: depth unknown—purple or maroon area of intact skin or blood-filled blister
- Synonyms: decubitus ulcer; bedsore; pressure injury

EPIDEMIOLOGY
Incidence
Dependent on setting and population: 0–53.4% (1,2)

Prevalence
Dependent on setting and population: 0–72.5% (1,2)

ETIOLOGY AND PATHOPHYSIOLOGY
Complex process of risk factors interacting with external forces (pressure and/or shear) (3)

RISK FACTORS
- Mobility impairment
- Malnutrition
- Reduced perfusion
- Sensory impairment
- Medical devices

GENERAL PREVENTION
- Structured risk assessment (1)
- Skin and tissue assessment (1)
- Preventive skin care (1)
- Nutrition screening (1)
- Repositioning (1)
- Early mobilization (1)
Support surfaces (1)
Microclimate control (1)
Prophylactic dressings (1)
Electrical stimulation of the muscles (1)

COMMONLY ASSOCIATED CONDITIONS
- Advanced age
- Immobility
- Trauma
- Hip fractures
- Diabetes
- Cerebrovascular and cardiovascular disease
- Incontinence

DIAGNOSIS

HISTORY
- Risk factors
- Nutritional assessment (1)
- Pain assessment (1)
- Date of ulcer diagnosis
- Treatment course

PHYSICAL EXAM
- Full skin examination on initial contact and repeatedly throughout visits
- Assess location, stage, size (length, width, depth); identify presence of sinus tracts, undermining, tunneling, exudate, necrosis, odor, and signs of healing (e.g., granulation tissue) (1).
- Identify factors that may affect healing (impaired perfusion, sensation, presence of infection).

DIFFERENTIAL DIAGNOSIS
- Venous ulcers
- Arterial ulcers
- Incontinence associated dermatitis
- Skin tears
- Intertrigo
- Neuropathic ulcers
- Pyoderma gangrenosum, cancers, vasculitides, and other dermatologic conditions

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Wound culture: Do not culture surface drainage. If culture necessary, do deep tissue culture/bone biopsy.
- If systemic infection or that of bone or muscle is suspected, then add infectious workup, including inflammatory markers, CBC, blood cultures, x-ray. MRI may be necessary to confirm osteomyelitis.
- Ankle-brachial index and Doppler ultrasound (for lower extremity wounds)
Follow-Up Tests & Special Considerations
Additional tests may be indicated when additional medical illness complicates assessment. This may include testing for diabetes (i.e., A1c), thyroid disease (i.e., TSH), vascular disease, and other dermatologic diagnoses.

TREATMENT
GENERAL MEASURES
- Comprehensive initial assessment of the patient
- Pressure reduction/redistribution (4)[A]
- Nutritional support (e.g., protein containing supplements) (5)[B]
- Wound assessment and treatment
  - Wound bed preparation (tissue management, infection and inflammation control, moisture balance, epithelial edge advancement) (1)
  - Wound cleansing (1)[C]
  - Débridement (1)[C]
- Address immobility.
- Manage incontinence.
- Address pain.
- Assess goals of care and advance directives.

MEDICATION
First Line
- Wound dressings as appropriate for category of ulcer (hydrocolloid, hydrogel, alginate, foam, silver impregnated, honey impregnated, cadexomer iodine, gauze, silicone, collagen matrix, composite) (1)[C]. Systematic reviews find evidence of superiority of one dressing compared to another is of poor quality. Therefore, it is impossible to recommend one dressing over another (6)[A].
- Enzymatic débriding agents

Second Line
- Activated charcoal
- Topical antiseptics (hydrogen peroxide, Dakin’s solution, povidone-iodine)

ISSUES FOR REFERRAL
- Consider referral to wound care specialist (if available) for complex or nonhealing wounds.
- Consider vascular surgery for improvement of blood flow to wound via vascular bypass if appropriate.
- Consider surgical consultation for possible urgent drainage and/or débridement if advancing cellulitis; suspected source of sepsis; undermining, tunneling, sinus tracts, and/or extensive necrotic tissue that cannot otherwise be removed by nonsurgical débridement methods; or for stage III or IV that are not closing with conservative management (1)[C].
- Consider plastic surgery for skin graft/flap if appropriate.
- Consider dermatology referral if suspected pyoderma gangrenosum, cancer, vasculitis or other dermatologic conditions.
ADDITIONAL THERAPIES
- Direct contact electrical stimulation for recalcitrant stage II and any category/stage III and IV (1)[A]
- Electromagnetic field for recalcitrant category/stage II and any stage III and IV (1)[C]
- Pulsed radio frequency energy for recalcitrant stage II and any stage III and IV (1)[C]

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Low-frequency ultrasound for débridement of necrotic soft tissue (not eschar) (1)[C]
- High-frequency ultrasound as adjunct for infected pressure ulcers (1)[C]
- Negative pressure wound therapy as early adjuvant treatment for deep, stage III and IV (1)[B]
- Consider course of hydrotherapy with pulsed lavage with suction for wound cleansing and débridement (1)[C]
- Phototherapy: short term UVC light if traditional therapies fail (1)[C]; laser not recommended (1)[C]; infrared is not recommended (1)[C].
- Hyperbaric and topical oxygen therapy not recommended for routine use (1)[C]
- Hydrotherapy with whirlpool should not be considered for routine use (1)[C]
- Vibration therapy not recommended (1)[C]
- Consider maggot débridement therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: refractory cellulitis, osteomyelitis, systemic infection, advanced nutritional decline, suspected patient mistreatment, inability to care for self
- Dressing changes 1 to 3 times daily based on wound assessment and plan of care.
- Assess risk factors according to scales.
- Assess for changing or new wounds.
- Discharge criteria: clinical improvement in wound and systemic illness; when applicable, safe, and appropriate location for discharge

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Weekly assessment by nurse with wound experience; biweekly assessment by physician

Patient Monitoring
- Home health nursing
- Change plan of care if no improvement in 2 to 3 weeks.

DIET
- Approximately 1.0 to 1.5 kg/day of protein
- Strict glycemic control
- Include micronutrients in diet or as supplements.

PATIENT EDUCATION
- Check skin regularly.
- Signs and symptoms of infection
- Report new or increased pain.
- Prevention of new wound where old wound healed
● Skin care, moisture prevention

**PROGNOSIS**
Variable, depending on the following:
● Removal of pressure
● Nutrition
● Wound care

**COMPLICATIONS**
● Infection
● Amputation

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
● L89.95 Pressure ulcer of unspecified site, unstageable
● L89.91 Pressure ulcer of unspecified site, stage 1
● L89.92 Pressure ulcer of unspecified site, stage 2

**CLINICAL PEARLS**
- Create assessment and prevention protocols for all patients.
- Identify risk factors, reduce/redistribute pressure, maximize nutrition, regular skin checks, and assess and treat wounds appropriately.
- All care needs to be done in time-sensitive, patient-centered fashion.
PRETERM LABOR
Kara M. Coassolo, MD ● John C. Smulian, MD, MPH

BASICS

DESCRIPTION
Contractions occurring between 20 and 36 weeks’ gestation at a rate of 4 in 20 minutes or 8 in 1 hour with at least one of the following: cervical change over time or dilation ≥2 cm

EPIDEMIOLOGY
Preterm birth is the leading cause of perinatal morbidity and mortality in the United States (1).

Incidence
10–15% of pregnancies experienced at least one episode of preterm labor.

Prevalence
10% of all births in the United States are preterm, of which 2/3 are spontaneous, and 1/3 are medically indicated.

ETIOLOGY AND PATHOPHYSIOLOGY

- Premature formation and activation of myometrial gap junctions
- Inflammatory mediator–stimulated contractions
- Weakened cervix (structural defect or extracellular matrix defect)
- Abnormal placental implantation
- Systemic inflammation/infections (e.g., urinary tract infection [UTI], pyelonephritis, pneumonia, sepsis)
- Local inflammation/infections (intra-amniotic infections from aerobes, anaerobes, Mycoplasma, Ureaplasma)
- Uterine abnormalities (e.g., cervical insufficiency, leiomyomata, müllerian anomalies, diethylstilbestrol exposure)
- Overdistension (by multiple gestation or polyhydramnios)
- Preterm premature rupture of membranes
- Trauma
- Placental abruption
- Immunopathology (e.g., antiphospholipid antibodies)
- Placental ischemic disease (preeclampsia and fetal growth restriction)

Genetics
Familial predisposition. Numerous gene candidates mediating various pathways (inflammation, apoptosis, coagulation, hypoperfusion, thrombosis, collagen remodeling) have been identified, but causality and gene-environment interactions are not well-defined.

RISK FACTORS
- Demographic factors, including single parent, poverty, and black race
- Short interpregnancy interval (<18 months)
- No prenatal care
- Prepregnancy weight <45 kg (100 lb), body mass index <20
• Substance abuse (e.g., cocaine, tobacco)
• Prior preterm delivery (common)
• Previous 2nd-trimester dilation and evacuation (D&E)
• Cervical insufficiency or prior cervical surgery (cone biopsy or loop electrosurgical excision procedure [LEEP])
• Abdominal surgery/trauma during pregnancy
• Uterine structural abnormalities, such as large fibroids or müllerian abnormalities
• Serious maternal infections/diseases
• Bacterial vaginosis
• Bacteriuria
• Vaginal bleeding during pregnancy
• Multiple gestation
• Select fetal abnormalities
• Intrauterine growth restriction
• Placenta previa
• Premature placental separation (abruption)
• Polyhydramnios
• Ehlers-Danlos syndrome

**GENERAL PREVENTION**

- Patient education at each visit in 2nd and 3rd trimesters for those at risk and periodically in the last two trimesters for the general population
- Routine transvaginal ultrasound cervical length (CL) measurements in singleton pregnancies in the mid-2nd trimester to detect increased risk for preterm birth (<20 mm) is an acceptable strategy (2) and may be especially helpful if risk factors for preterm delivery are present.
- Primary prevention:
  - Interval contraception to optimize pregnancy spacing
  - Smoking cessation
  - If previous preterm birth, evaluate if etiology is likely to recur and target intervention to specific condition.
    o Weekly injections of 17α-hydroxyprogesterone (250 mg IM every week) from 16 to 36 weeks if previous spontaneous preterm birth
    o Consider cerclage (2)[A] or pessary placement (3)[B] before 24 weeks’ gestation for those at high risk because of cervical insufficiency or significant or progressive cervical shortening.
- Secondary prevention:
  - For women with a short cervix in the 2nd trimester (<20 mm on transvaginal US), progesterone 200 mg/day per vagina for 24 to 34 weeks may decrease the risk of preterm delivery (3)[A],(4)[B].
    - Tocolysis

**DIAGNOSIS**

Diagnosis is generally based on a combination of significant cervical changes (such as dilation, effacement) with regular contractions. However, there is no single test that will reliably diagnose or predict true preterm labor. The diagnosis is based on a combination of physical findings and
diagnostic tests that are interpreted in the context of the degree of risk to the patient.

**HISTORY**
- Address risk factors, especially etiologies of previous preterm birth.
- Regular uterine contractions or cramping
- Dull, low backache or pain
- Intermittent lower abdominal pain
- Increased low pelvic pressure
- Change in vaginal discharge
- Vaginal bleeding
- Fluid leakage

**PHYSICAL EXAM**
- Sterile speculum exam for membrane rupture evaluation, cultures, and cervical inspection
- Bimanual cervical exam if intact membranes: dilation of the cervix >1 cm and/or effacement of the cervix >50%

**ALERT**
Avoid bimanual examination when possible if rupture of the membranes is suspected.

**DIFFERENTIAL DIAGNOSIS**
- Braxton-Hicks contractions/false labor
- Round ligament pain
- Lumbosacral muscular back pain
- UTI or vaginal infections
- Adnexal torsion
- Degenerating fibroid
- Appendicitis
- Dehydration
- Viral gastroenteritis
- Nephrolithiasis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- There are no specific tests that completely accurately predict preterm birth, although several can help with risk stratification.
- In symptomatic women from 22 to 34 weeks’ gestation with intact membranes and no intercourse or bleeding in past 24 hours, obtain a fetal fibronectin (FFN) swab from the posterior vaginal fornix. FFN must be obtained prior to digital cervical exam (2).
  - If results are positive (≥50 ng/mL), patient is at a modest increased risk of preterm birth (positive predictive value [PPV] 13–30% for delivery within 2 weeks).
  - If results are negative, >97% of patients will not deliver in 14 days, so can consider avoiding complicated or high-risk interventions.
- Urinalysis and urine culture
- Cultures for gonorrhea and chlamydia
- Wet prep for bacterial vaginosis evaluation (although evidence for improved outcomes with treatment is weak)
- Vaginal introitus and rectal culture for group B Streptococcus
- pH and ferning test of vaginal fluid to evaluate for rupture of membranes
- CBC with differential
- Drug screen when appropriate
- Kleihauer-Betke test if abruption suspected
- US to identify number of fetuses and fetal position, confirm gestational age, estimate fetal weight, quantify amniotic fluid, and look for conditions making tocolysis contraindicated
- Transvaginal US to evaluate CL, funneling, and dynamic changes after obtaining FFN (if clinical assessment of the cervix is uncertain or if the cervix is closed on digital exam) (2)

**Follow-Up Tests & Special Considerations**
- Repeat FFN as indicated by symptoms.
- After successful treatment, progressive changes of the cervix on repeat examination or US (in 1 to 2 weeks) may indicate need for hospitalization.

**Diagnostic Procedures/Other**
- Monitor contractions with external tocodynamometer.
- Consider amniocentesis at any preterm gestational age to evaluate for intra-amniotic infection (cell count with differential, glucose, Gram stain, aerobic, anaerobic, Mycoplasma, Ureaplasma cultures).

**Test Interpretation**
- Placental inflammation
  - Acute inflammation usually caused by infection
  - Chronic inflammation caused by immunopathology
- Abruption

---

**TREATMENT**

**GENERAL MEASURES**
- Treat underlying risk factors (e.g., antibiotics for infections, hydration for dehydration).
- Liquids only or NPO if delivery is imminent
- Hospitalization is necessary if the patient is on IV tocolysis.

**MEDICATION**

Tocolysis may allow time for interventions such as transfer to tertiary care facility and administration of corticosteroids but may not prolong pregnancy significantly (4)[A].

**First Line**
- Tocolysis (4)[A]
  - Nifedipine: 30 mg PO loading dose, then 10 to 20 mg q6h for 24 hours, and then 10 to 20 mg PO q8h (do not use sublingual route); check BP often and avoid hypotension. Concurrent use with magnesium sulfate is discouraged due to the theoretical risk of neuromuscular blockade.
  - Indomethacin: 50 to 100 mg PO initial dose and then 25 to 50 mg q6–8h. Use for longer than 72 hours is not recommended due to risk of premature closure of ductus arteriosus, oligohydramnios, and possibly neonatal necrotizing enterocolitis. Use with caution in patients with platelet dysfunction, liver dysfunction, or allergy to aspirin.
Contraindications to tocolysis: severe preeclampsia, hemorrhage, chorioamnionitis, advanced labor, intrauterine growth restriction, fetal distress, or lethal fetal abnormalities

- Antibiotics: antibiotics for group B Streptococcus prophylaxis if culture is positive or unknown
- Steroids: If mother is at 23 to 34 weeks’ gestation with no evidence of systemic infection, give glucocorticoids to decrease neonatal respiratory distress, intraventricular hemorrhage, necrotizing enterocolitis, and overall perinatal mortality; betamethasone 12 mg IM × 2 doses 24 hours apart (preferred choice) or dexamethasone 6 mg IM q12h for 4 doses (5)[A]

- Steroids may reduce the risk of respiratory morbidities in singleton infants born to nondiabetic mothers in the late preterm period (34 + 0 to 36 + 6 weeks’ gestation). If delivery is likely during this time period, administration of steroids may be considered as above. Tocolysis is not recommended.

**Second Line**

- Magnesium sulfate by IV infusion has not been shown to be superior to placebo in prolonging pregnancy beyond 48 hours. The side effects are generally greater than those with calcium channel blockers or NSAIDs. Therefore, this agent should be used cautiously (standard dosages for tocolysis start with a 4- to 6-g IV bolus over 20 minutes followed by 2- to 3-g/hr infusion until contractions stop).
  - Magnesium may decrease the risk of cerebral palsy when 12-hour course is given prior to an anticipated preterm birth.
  - Relative contraindications to magnesium sulfate include myasthenia gravis, hypocalcemia, renal failure, or concurrent use of calcium channel blockers.
- Terbutaline 0.25 mg SC q30min for up to 3 doses until contractions stop and then 0.25 mg SC q6h for 4 doses (optional); if contractions persist or pulse >120 bpm, change to another tocolytic agent (may be poorly tolerated by mothers).
- Terbutaline PO or by infusion pump has been used in the past for treatment or prevention of preterm labor. Due to reports of serious cardiovascular events and maternal deaths, PO or long-term SC administration of terbutaline should not be given.
- Significant possible interactions include pulmonary edema from crystalloid fluids and tocolytic agents, especially magnesium sulfate.
- PO maintenance therapy with any agent does not improve outcomes and is not recommended.

**ISSUES FOR REFERRAL**

- If delivery is inevitable but not immediate, consider transport to a tertiary care center or hospital equipped with a neonatal ICU.
- Consider consultation with maternal–fetal medicine specialist.

**ADDITIONAL THERAPIES**

- Pelvic rest (e.g., no douching or intercourse) and activity restriction are often recommended; however, data to prove the efficacy are lacking. Some reduction in physical activity may be reasonable; this should be individualized.
- Strict bed rest has not been demonstrated to be effective in most situations.

**SURGERY/OTHER PROCEDURES**

- For malpresentation or fetal compromise, consider cesarean delivery if labor is progressing.
- Consider cerclage for cervical insufficiency (until 24 weeks’ gestation).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
● Suspected/threatened preterm labor
  – IV access
  – Continuous fetal and contraction monitoring
  – Assess cervix for dilatation and effacement.
  – Hydrate with 500 mL 5% dextrose normal saline solution or 5% dextrose lactated Ringer solution for first half hour and then at 125 mL/hr.
  – Monitor for fluid overload (input/output monitoring, symptoms, lung auscultation, pulse oximetry), especially with tocolysis and multiple gestations.

● Discharge criteria
  – Regular contractions and cervical change resolve.
  – If cervix is dilated ≥3 cm or FFN is positive, individualize decision to discharge by gestational age and patient circumstances.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
● Weekly office visits with contraction monitoring, cervical checks, or cervical US if at high risk for recurrence
● Routine use of maintenance tocolysis is ineffective in preventing recurrent preterm labor or preterm birth.

DIET

Regular

PATIENT EDUCATION

Call physician or proceed to hospital whenever regular contractions last >1 hour, bleeding, increased vaginal discharge or fluid, decreased fetal movement.

PROGNOSIS
● If membranes are ruptured and no infection is confirmed, delivery often occurs within 3 to 7 days.
● If membranes are intact, 20–50% deliver preterm.

COMPLICATIONS

Labor resistant to tocolysis, pulmonary edema, infection with preterm rupture of membranes

REFERENCES

ADDITIONAL READING

CODES

ICD10

- O60.00 Preterm labor without delivery, unspecified trimester
- O60.02 Preterm labor without delivery, second trimester
- O60.03 Preterm labor without delivery, third trimester

CLINICAL PEARLS

- Treatment of preterm labor may delay delivery to facilitate short-term interventions.
- Steroids improve neonatal outcomes.
- Progesterone therapy can prevent recurrence of preterm birth in next pregnancy.
PRIAPISM
David L. Lee, MD • Munima Nasir, MD

BASICS

DESCRIPTION
- Penile (or less common clitoral) erection lasting for >4 hours and unrelated to sexual stimulation or arousal
- Classified into three types: ischemic, nonischemic, and stuttering:
  - Ischemic (low-flow, veno-occlusive) priapism, associated with ischaemia of the corpora cavernosa, is prolonged and painful and requires urgent clinical intervention.
  - Nonischemic (high-flow, arterial) priapism is less common and often painless, may be related to prior trauma, and does not require urgent treatment.
  - Stuttering priapism (recurrent, ischemic) is episodic, short-lived, and may not require intervention.
- Malignant priapism is a rare condition resulting most commonly from penile metastases related to primary bladder, prostatic, rectosigmoid, and renal tumors.
- System(s) affected: reproductive and vascular
- Functional impairment: neurophysiologic, sexual, psychosocial (quality of life) (1)

Pediatric Considerations
- In children, nearly all cases are related to hemoglobinopathies including sickle cell disease (SCD) (63% of cases). Less commonly related etiologies, occurring more typically in the adolescent years, are leukemia; idiopathic, penile trauma (e.g., post circumcision); or illicit drugs (up to 35% of cases).
- Neonatal priapism is also rare, occurring in the first few days of life (2).

EPIDEMIOLOGY

Incidence
- The incidence and prevalence of priapism is likely underestimated because medical literature only includes cases in which men sought medical intervention. In a study of emergency department visits in the United States, there is an incidence of 5.3 per 100,000 men per year; accounting for up to 8 out of every 100,000 emergency department visits (3). In the Netherlands, the incidence was 1.5 per 100,000 men per year (4).
- Age: There has been an age shift since 2008 toward men in their 40s. The incidence doubles in men ages >40 years (2.9 vs. 1.5/100,000 person-years).
- Race: 61.1% black (correlated with incidence of SCD), 30% white, 6.3% Hispanic

ETIOLOGY AND PATHOPHYSIOLOGY
- Anatomy and physiology:
  - The penis consists of three longitudinally oriented corpora: two dorsolaterally paired corpora cavernosa that are responsible for penile erection and a single ventral corpus spongiosum that surrounds the glans penis and extends distally to form the glans penis.
  - In general, the penile artery (a branch of the internal pudendal artery that, in turn, is a branch from the internal iliac artery) supplies the penis. It divides into three branches: dorsal artery, bulbar artery (supplies the corpus spongiosum), and cavernosal artery (the
main blood supply to the erectile tissue).

- During an erection, smooth muscle relaxation of the cavernosal arterioles results in high-volume inflow to the sinusoids, resulting in compression of the exiting venules. This leads to significant volume expansion of the corpora cavernosa.
- During the flaccid resting state, the sympathetic nervous system is predominantly in control. Penile tumescence and erection are driven by the parasympathetic nervous system through the generation of nitric oxide.
- Smooth muscle relaxation occurs via usage of the phosphodiesterase type 5A (PDE5A) pathway, which generates cyclic guanosine monophosphate (cGMP) (2).

- In ischemic priapism (accounting for >95% of reported episodes), decreased venous outflow results in increased intracavernosal pressure. This leads to erection, decreased arterial inflow, blood stasis, local hypoxia, and acidosis (a compartment syndrome). Penile tissue necrosis and fibrosis may occur if priapism persists >24 hours. The exact mechanism is unknown and may involve trapping of erythrocytes in the veins, draining the erectile bodies.
- In nonischemic priapism, increased arterial flow without decreased venous outflow results in a sustained, nonpainful, partially rigid erection.
- Aberrations in the PDE5A pathway have been proven in mice to be one mechanism of priapism (1).

Causes: ischemic priapism (1)
- Idiopathic, estimated to about 50%
- Hematologic dyscrasias (sickle cell disease, thalassemia, leukemia, multiple myeloma, fat emboli during hyperalimentation, hemodialysis, glucose-6-phosphate dehydrogenase deficiency, factor V Leiden mutation)
- Infections (toxin mediated) (i.e., urinary tract infections, scorpion sting, spider bite, rabies, malaria)
- Metabolic disorders (i.e., nephrolithiasis, amyloidosis, Fabry disease, gout)
- Neurogenic disorders (i.e., syphilis, spinal cord injury, cauda equina syndrome, autonomic neuropathy, lumbar disc herniation, spinal stenosis, cerebrovascular accident, brain tumor, spinal anesthesia)
- Neoplasms (metastatic or regional infiltration; most commonly: penis, urethra, bladder, prostate, kidney, and rectum)
- Medications associated with priapism include: vasoactive erectile agents (i.e., papaverine, phentolamine, prostaglandin E1/alprostadil), α-adrenergic receptor antagonists (i.e., prazosin, terazosin, doxazosin, tamsulosin), anxiolytics (hydroxyzine), anticoagulants (heparin, warfarin), antidepressants and antipsychotics (i.e., trazodone, bupropion, fluoxetine, sertraline, lithium, clozapine, risperidone, olanzapine, chlorpromazine, thioridazine, phenothiazines), antihypertensives (i.e., hydralazine, guanethidine, propranolol), hormones (i.e., gonadotropin-releasing hormone, testosterone), and recreational drugs (i.e., alcohol, marijuana, cocaine [intranasal and topical], crack, cocaine) (4)

Causes: nonischemic priapism (1)
- The most common cause is penile or perineal trauma resulting in a fistula between the cavernous artery and the corpus cavernosum.
- Acute spinal cord injury
- Rarely, the management of ischemic priapism can result in iatrogenic nonischemic priapism.
– Certain urologic surgeries have also resulted in nonischemic priapism.

**RISK FACTORS**
- SCD has a lifetime risk of ischemic priapism 29–42%.
- Dehydration correlated with SCD or trait
- Prior history of priapismic episodes (stuttering priapism) (1,2)

**GENERAL PREVENTION**
- Avoid dehydration (SCD cases).
- Avoid excessive sexual stimulation.
- Avoid or limit causative drugs (see “Etiology and Pathophysiology”).
- Avoid physical activity with a high risk of blunt trauma to the genital area (1,2).

**COMMONLY ASSOCIATED CONDITIONS**
- SCD (42.9%) or sickle cell trait (2.5%)
- Drug abuse (7.9%)
- G6PD deficiency
- Leukemia
- Neoplasm

**DIAGNOSIS**

**HISTORY**
- Prior priapism episodes or prolonged erections after waking and degree of pain
- Duration of erection
- Perineal or penile trauma (blunt force or needle injury)
- Urination difficult during erection
- History of any hematologic abnormalities (e.g., SCD or trait)
- Cardiovascular disease
- Medications
- Recreational drug use

**PHYSICAL EXAM**
- In general, physical examination should include:
  - A complete penile, scrotal, and perineal exam to identify the presence of trauma, gangrene (rare), or prosthesis
  - An abdominal and lymph node exam to rule out underlying conditions
- Observations upon examination should include:
  - Ischemic (or stuttering) priapism: Penis is fully erect, painful, or tender; corpora cavernosa are rigid; and corpora spongiosum and glans are flaccid.
  - Nonischemic priapism: Penis is partially erect (not tender or painful), and the corpora cavernosa are semirigid and nontender, with the glans and corpora spongiosum flaccid.

**DIAGNOSTIC TESTS & INTERPRETATION**
- CBC with reticulocyte count to detect leukemia or platelet abnormalities
- Sickling hemoglobin (Hgb) solubility test and Hgb electrophoresis
- Coagulation profile
Platelet count
Urinalysis/urine toxicology
Corporal blood gas (CBG) should be obtained to distinguish ischemic from nonischemic priapism.
A color duplex or Doppler ultrasound of the penis and perineum may be necessary to differentiate ischemic (no blood flow in the cavernosal arteries) from nonischemic (high blood flow) priapism (1)[C]; pelvic vascular thrombosis, partial thrombosis of corpora cavernosa, and corpus spongiosum may be detected.
Penile arteriography can be used to identify the presence and arterial cavernous fistula or pseudoaneurysms (nonischemic) (5).
Penile MRI can be used for cases >48–72 hour duration to evaluate for corporal smooth muscle necrosis and candidacy for immediate penile prosthesis implantation (4)
Subjective assessment measure: International Index of Erectile Function (IIEF-5) questionnaire (6)

**TREATMENT**

Treatments for priapism are determined based on the three main types: ischemic, nonischemic, and stuttering (7).
- Ischemic priapism requires immediate treatment to preserve future erectile function (a longer delay in treatment means a higher chance of future impotence and possibly necrosis). Urgent urologic consultation is recommended.
  - Cavernosal aspiration with a large bore needle with irrigation (success rate ~30%) (1,7) [C]
  - Cavernosal injection of phenylephrine (α-adrenergic sympathomimetic) with monitoring of patient’s BP and pulse (success rate between 43% and 81%) (7)[C]. Inject q5min until detumescence (15 to 60 minutes).
  - Continue aspiration, irrigation, and phenylephrine for several hours. If this fails, shunt (e.g., distal) procedures are considered.
- Nonischemic priapism
  - Observation, icing, site specific compression; causative fistula may close spontaneously (7)[B]
    - If nonischemic priapism does not resolve arteriography and selective embolization
- Stuttering priapism
  - The initial goal is to prevent future priapismic episodes; if episodes become prolonged, there is a risk of conversion to ischemic priapism (7).
  - Manage acute episodes as ischemic cases—aspiration and irrigation and then intracavernous injections of α-adrenergic agonists (e.g., pseudoephedrine and etilefrine 50 to 100 mg daily is effective in approximately 72% of cases) (7,8).
  - Prevention of recurrence with daily oral medications:
    - Adrenergic agonists: pseudoephedrine and etilefrine
    - Androgen suppression: antiandrogens, 5α-reductase inhibitors, and ketoconazole
    - Smooth muscle regulation: digoxin or terbutaline
    - Others: gabapentin, baclofen, hydroxyurea (4)
- Conservative treatment (successful particularly with children) consists of applying ice to the perineum or perineal compression (1).
In all cases, particularly SCD cases, treat the underlying condition (e.g., SCD does not delay intracavernous treatment).

Although blood transfusion is an option, particularly in SCD cases, other interventions should be explored and exhausted first.

There are no widely accepted guidelines on treatment among children (2).

GENERAL MEASURES
- Discuss the prognosis with the patient.
- Relieve the patient’s pain; do not delay this while waiting for urologic consultation. Provide continuous caudal or spinal anesthesia if the etiology is neurogenic.
- Treat any underlying cause or disease process.
- In SCD cases: IV hydration; supplemental oxygen; partial exchange or repeated transfusions to reduce percentage of sickle cells to <50%
- Initiating proper management depends on whether the priapism is ischemic or nonischemic.

MEDICATION
- Analgesics (e.g., opioids) for pain, if needed
- Intracavernous injection of phenylephrine is considered to be first line, as it minimizes risk of cardiovascular side effects that are more common with other sympathomimetics.
- Ketoconazole 200 mg TID and prednisone 5 mg daily for 2 weeks; then, tapering to ketoconazole 200 mg nightly for 6 months has been shown (with limited evidence) to prevent recurrent ischemic priapism (4).

Second Line
For ischemic priapism:
- Etillefrine (intracavernous) is a the second most used sympathomimetic.
- Methylene blue (intracavernous) can be used for pharmacologically induced priapism (cGMP inhibitor).
- Epinephrine (intracavernous) has a higher success rate than phenylephrine, but greater cardiovascular side effects.
- Terbutaline (oral) can be used alongside intracavernous therapies; mechanism of action not completely understood (4).

ISSUES FOR REFERRAL
A urologist should be consulted in all cases of suspected priapism to ensure the highest likelihood of preserved reproductive and vascular function.

SURGERY/OTHER PROCEDURES
- For ischemic priapism, surgical options after medical therapy include:
  - Distal cavernoglandular shunts (first line)
    o Percutaneous: Ebbehoj, Winter, or T shunt
    o Open: Al-Ghorab or Burnett
  - Proximal cavernoglandular shunts
    o Open: Quackles or Sacher
  - Venous shunts
    o Greyhack (saphenous vein shunt)
    o Barry (deep dorsal vein shunt)
  - Immediate penile prothesis placement: relative indications include failure of intracavernous
therapies or corporal smooth muscle necrosis or MRI/biopsy; early surgery avoids cavernous fibrosis, which offers the opportunity to maintain penile size and prevent penile curvature due to cavernosal fibrosis.

- For nonischemic priapism, surgical options include:
  - Selective embolization with autologous blood clot, absorbable (gel foam or sponge) or nonabsorbable materials (coils or acrylic glue) (5% rate of impotence vs. 39% absorbable vs. permanent materials), or surgical ligation as a last resort (4)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Further evaluation of underlying etiologies and reduction of vasoactive drug therapy as indicated

**Patient Monitoring**
Close follow-up with a urologist is recommended.

**PATIENT EDUCATION**
Provide information about long-term outlook, referral for counseling, and options if patient is suffering from erectile dysfunction as a result of priapism.

**PROGNOSIS**
- Even with excellent treatment for a prolonged priapism, complete detumescence may require several weeks secondary to edema.
- Impotence due to irreversible corporal fibrosis is likely in ischemic priapism and is up to 90% if the priapism lasts >24 hours (1).

**COMPLICATIONS**
Erectile dysfunction (i.e., impotence)

**REFERENCES**

Anemia, Sickle Cell; Erectile Dysfunction

CODES

ICD10

- N48.30 Priapism, unspecified
- N48.39 Other priapism
- N48.31 Priapism due to trauma

CLINICAL PEARLS

- Priapism is a prolonged penile erection that lasts >4 hours and is unrelated to sexual stimulation. If priapism lasts >24 hours, it likely results in permanent sexual impairment.
- Priapism can occur in children, particularly in SCD. Treatment should address both the underlying disease as well as developmental needs.
- In evaluating priapism, the clinician must distinguish ischemic from nonischemic priapism by history and physical exam as well as cavernosal blood gas and possibly ultrasound, if indicated.
- Ischemic priapism is an emergent condition that requires immediate urologic evaluation and treatment.
- The most common causes of ischemic priapism are idiopathic, related to SCD, iatrogenic, or treatments for erectile dysfunction, or related to use of recreational or medicinal substances.
PROSTATE CANCER
Alex M. Hennessey, MD  Joseph R. Wagner, MD

BASICS

DESCRIPTION
- The prostate is a male reproductive organ that contributes seminal fluid to the ejaculate.
- The prostate gland is about the size of a walnut, averaging 20 to 25 g in volume in an adult male; tends to enlarge after age 50 years.
- Three distinct zones delineate the functional anatomy of the prostate: peripheral zone (largest, neighbors rectal wall, palpable on digital rectal exam (DRE), most common location for prostate cancer), central zone (contains the ejaculatory ducts), and transition zone (located centrally, adjacent to the urethra).
- Prostatic epithelial cells produce prostate-specific antigen (PSA), which is used as a tumor marker and in screening.

EPIDEMIOLOGY

Incidence
According to the National Cancer Institute SEER data, an estimated 164,690 men in the United States will be diagnosed with carcinoma of the prostate (CaP) in 2018 (1).

Prevalence
- About 3 million men are living with CaP in the United States (1).
- An estimated 29,430 men in the United States will die of CaP in 2018 (1).
- Mean age at diagnosis is 66 years.
- Prostate cancer is the most commonly diagnosed nonskin cancer in men in the United States (~11.6% lifetime risk) and second leading cause of cancer death in men (only ~3% of all CaP results in CaP-related death) (1).
- Autopsy studies find foci of latent CaP in 50% of men in their 8th decade of life.
- Probability of clinical CaP 10.9% (1 in 9) in men ages ≥70 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Adenocarcinoma: >95%; nonadenocarcinoma: <5% (most common transitional cell carcinoma)
- Cells generally stain positive for PSA and prostatic acid phosphatase (PAP).
- Location of CaP: 70% peripheral zone, 20% transitional zone, 5–10% central zone

Genetics
Elevated risk if first-degree relative diagnosed with CaP suggesting genetic component; specifics unclear

RISK FACTORS
- Age >50 years
- African American race
- Positive family history
- Poorly understood environmental factors
GENERAL PREVENTION
There are no FDA-approved drugs or diet modifications to prevent CaP.
- Finasteride has been studied for this purpose in a phase III trial called the Prostate Cancer Prevention Trial. A moderate risk reduction associated with an increased risk of high-grade disease was encountered. Therefore, it has not been FDA-approved for prevention (2).

ALERT
Screening for prostate cancer is controversial:
- U.S. Preventive Services Task Force (USPSTF) final recommendation statement states, “For men aged 55 to 69 years, the decision to undergo periodic PSA-based screening for prostate cancer should be an individual one and should include discussion of the potential benefits and harms of screening with their clinician.” Screening offers a small potential benefit of reducing the chance of death from prostate cancer in some men. However, many men will experience potential harms of screening. (Grade B) (3)[A].
- USPSTF recommends against PSA screening for men ≥70 years old (3)[A].
- PSA screening is not recommended in men age <40 years, or any man with <10 years of estimated life expectancy.
- When providing informed consent, the data show that if 1,000 men between 55 and 69 years are screened:
  - 240 will have a positive result.
  - ~100 will have prostate cancer.
  - Of the 100 with cancer, 80 will agree to treatment.
  - One person will avoid dying from screening.
  - 50 will develop erectile dysfunction (ED); 15 permanent incontinence

DIAGNOSIS
HISTORY
- Inquire about family history of CaP, symptoms of bladder outlet obstruction, and other voiding symptoms.
- Anorexia and weight loss, bone pain or neurologic deficits from spinal cord compression (with metastasis), hematuria, hematospermia (rare)

PHYSICAL EXAM
- DRE to assess for prostatic masses, firmness, or asymmetry
- Evaluate lumbar spine and lymph nodes for evidence of metastasis.

DIFFERENTIAL DIAGNOSIS
Benign prostatic hyperplasia, prostatitis, prostatic intraepithelial neoplasia (PIN), prostate stones, atypical small acinar proliferation (ASAP)

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
PSA, DRE, and clinical history primarily determine need for prostate biopsy:
- In general, total PSA ≥4 ng/mL is concerning for CaP (sensitivity 21%, specificity 91%).
  - Other benign conditions can elevate PSA (infection, inflammation, normal growth, natural
PSA fluctuations, normally high variants).
- Rectal manipulation will not significantly elevate PSA.
- Age, race, and family history need to be considered when interpreting PSA results.
- 5α-reductase inhibitors decrease PSA by ~50% (2).
- Other PSA metrics used to aid in CaP diagnosis: PSA velocity, PSA doubling time, PSA density (PSAD), percentage free PSA
  - Total PSA velocity: ≥0.75 ng/mL/year or >20% baseline for higher values increases CaP risk.
  - Free PSA and age-/race-adjusted PSA helpful in evaluating risk. For patients with PSA between 4 and 10 ng/mL, a low percent free PSA is associated with higher risk of CaP.
  - PSAD ≥0.15 associated with higher prevalence of CaP
  - Screening tests that utilize adjunctive serum/urine biomarkers in conjunction with clinical information to predict CaP risk are also available (e.g., 4K score, PHI).
- Prostate biopsy
  - Decision to biopsy involves PSA, DRE findings, adjunctive tests, and overall clinical suspicion of CaP with consideration of comorbidities and life expectancy.
  - Standard biopsy includes systematic random cores from the peripheral zone base, mid, and apex, generally 8 to 12 cores.
  - The Gleason grade is the standard pathologic grading system but is being replaced by grade groups 1 to 5.
    - Gleason grade ranks specimens from 1 (most differentiated) to 5 (least differentiated) based on architectural pattern identified.
    - Primary and secondary patterns are identified and reported, and the sum is the Gleason score (e.g., 3 + 4 = 7).
    - Most prostate cancer is scored 6 to 10, with 10 having the worst prognosis.
    - Grade group 1 = Gleason 6;
      grade group 2 = Gleason 3 + 4 = 7;
      grade group 3 = Gleason 4 + 3 = 7;
      grade group 4 = Gleason 8;
      grade group 5 = Gleason 9/10
- Staging (4)
  - TNM (tumor, node, and metastasis) staging used to generate a clinical and pathologic stage, which directs treatment. Clinical staging is as follows:
    - T1: cancer found incidentally on TURP or found on biopsy for elevated PSA
    - T2: cancer found on DRE but confined to the prostate
    - T3: cancer found to be extended locally outside of the prostate and/or the seminal vesicle
    - T4: invading adjacent organs
    - N1: denotes local lymph node spread
    - M1: distant metastasis

Follow-Up Tests & Special Considerations
- Some combination of bone scan, MRI, CT scan, or PET scan may be indicated for high-risk cancers.
- Biopsy if suspicious nodal findings
- Alkaline phosphatase associated with bony metastasis
- Genetic testing (e.g., Prolaris, Oncotype Dx, Decipher) is emerging as a prognostic modality.
TREATMENT

Use Prostate Predict Calculator to help patient consider treatment options: https://prostate.predict.nhs.uk/

Treatment options include (4):

- Watchful waiting: monitoring with expectation to provide palliation with symptoms
- Active surveillance: close monitoring of PSA, DRE, and repeat biopsy at regular intervals
- Radical prostatectomy: ± pelvic lymph node dissection (PLND)
- Radiation therapy: external beam (EBRT)
- ProtecT trial (2016) found watchful waiting had equal cancer-specific and all-cause mortality compared to surgery or radiotherapy. In the treatment arms, there was less disease progression (including metastatic disease) but resulted in significantly more morbidity (urinary and bowel dysfunction, ED) (5).
- Brachytherapy: radioactive implants placed in prostate; option for early clinical stage localized to the prostate
- Antiandrogen therapy
  - Bilateral orchiectomy (surgical castration)
  - Gonadotropin-releasing hormone (GnRH) agonist, antagonist, or antiandrogen (medical castration)
  - Abiraterone: 17α-hydroxylase inhibitor (CYP17A adrenal androgen production)
  - Bicalutamide/nilutamide/flutamide/enzalutamide/apalutamide: androgen receptor antagonists
- Chemotherapy: includes multiple chemotherapeutic agents used to treat castrate-resistant prostate cancer (CRPC)
- Risk factors
  - Treatment options based on risk: low-, intermediate-, and high-risk categories; this is based on risk of recurrence after definitive treatment. Must meet all three criteria to be low risk; any one criterion moves patient to a higher risk group (4): risk category clinical stage/serum PSA (ng/mL)/Gleason score: low T1–T2a/<10/≤6; intermediate T2b–T2c/>10 and ≤20/7; high T3a/>20/8 to 10
  - Updated risk stratification algorithms include additional groups of very low risk, favorable and unfavorable intermediate risk, and very high risk.
- Localized CaP
  - Low risk:
    - Mainstay of therapy is active surveillance.
    - Radical prostatectomy and radiation therapy may be offered.
  - Intermediate risk:
    - Mainstay of therapy is radical prostatectomy or radiation therapy.
    - Radical prostatectomy has shown a possible survival benefit in intermediate prostate cancer.
  - High risk:
    - Mainstay of therapy is radical prostatectomy or radiation therapy.
    - Adjuvant radiation may be considered based on adverse pathologic findings after prostatectomy.
Life expectancy determination as well as educating the patient of the risks and benefits of surveillance and treatment options is critical.

- **Locally advanced CaP:**
  - Mainstay of therapy is ADT and radiation; surgery and adjuvant radiation also used
  - Adding abiraterone + prednisone in patients commencing long-term ADT for high risk (T3–T4, Gleason 8 to 10, PSA >40), locally advanced prostate cancer has been shown to significantly increase overall survival (6).

- **Metastatic CaP:**
  - Mainstay of therapy is RT and ADT.
  - Early chemotherapy (docetaxel) with ADT may be considered for high-volume disease;
    ADT with abiraterone + prednisone for lower volume disease
  - ADT specifics:
    - GnRH agonists include leuprolide or goserelin.
    - GnRH antagonists include degarelix: an alternative to GnRH agonists; suppresses testosterone production and avoids flare phenomenon observed with GnRH agonists
    - Side effects of ADT: osteoporosis, gynecomastia, ED, decreased libido, obesity, lipid alterations, diabetes, and cardiovascular disease
    - Flare phenomenon (disease flare: hot flashes, fatigue) can occur owing to transient increase in testosterone levels on initiation of GnRH agonist therapy.
    - If spinal cord metastases are present, the concern for cord compression with a testosterone flare can be avoided by starting antiandrogen therapy prior to initiation of a GnRH agonist.
    - Combined androgen blockade with GnRH agonist and antiandrogen (e.g., bicalutamide, nilutamide, or flutamide) may be used to prevent flare.

- **CRPC**
  - CRPC is defined as progression of disease following ADT. Treatment includes the following:
    - Nonmetastatic
      - Continue ADT.
      - Add antiandrogen (apalutamide or enzalutamide).
    - Asymptomatic metastatic: no previous therapy with docetaxel:
      - Abiraterone: inhibitor of CYP17A (adrenal androgen production), used with prednisone
      - Enzalutamide: androgen receptor inhibitor
      - Docetaxel: chemotherapeutic that inhibits microtubules
      - Sipuleucel-T: immunotherapy
    - Symptomatic metastatic: no previous therapy with docetaxel
      - Abiraterone, enzalutamide, docetaxel
      - Radium-223 (radiopharmaceutical) for patients with symptomatic bony metastases and no visceral metastasis
    - Symptomatic metastatic: previous therapy with docetaxel:
      - Good performance status: abiraterone, enzalutamide, cabazitaxel
      - Poor performance status: Mainstay is palliative care; may attempt further therapy based on patient wishes

- **Bone health**
  - Men with prostate cancer, particularly those of older age or on ADT, are at elevated risk of pathologic fractures/skeletal events
Bone density studies should be followed.
Calcium and vitamin D should be offered.
Denosumab (RANK-ligand inhibitor—prevents osteoclast activation) and zoledronic acid (bisphosphonate) can be offered for prevention.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Prostatectomy: PSA and DRE are recommended at regular intervals. PSA threshold-defining biochemical recurrence is evolving; however, recent data suggest a cutoff of 0.2 ng/mL (4). Some combination of CT/MRI/PET/bone scan usually obtained at recurrence. If the PSA recurrence is due to local disease, salvage radiation is considered. For metastatic disease, androgen deprivation is considered (4).
- XRT: PSA and DRE are recommended at regular intervals. Biochemical recurrence is defined as PSA increase ≥2 ng/mL above nadir; some combination of CT/MRI/PET/bone scan is usually obtained. If the PSA recurrence is thought to be from local disease, salvage prostatectomy or cryosurgery is considered. For metastatic disease, androgen deprivation is considered (4).

PROGNOSIS

- Localized disease is frequently curable; advanced disease has a favorable prognosis if lesions are hormone sensitive.
- 5-year CaP survival by stage: local 100%, regional 100%, distant 29.3% (1)
- Recurrence risk increased if adverse pathologic features are present: extraprostatic extension, seminal vesicle invasion, positive surgical margins.

COMPLICATIONS

- Prostatectomy: Urinary incontinence and ED are the most common long-term issues.
- Radiation therapy: urinary incontinence, ED, radiation cystitis, and radiation proctitis
- Treatment options for ED: PDE5 inhibitors, intracavernosal injections, intraurethral suppositories, vacuum pump, penile prosthesis
- Treatment options for incontinence: oral medications, urethral sling, artificial sphincter

REFERENCES

ADDITIONAL READING

CODES

ICD10
C61 Malignant neoplasm of prostate

CLINICAL PEARLS

- Prostate cancer is clinically diverse, ranging from low-risk/indolent disease to high-risk/aggressive disease.
- Most men with CaP are asymptomatic.
- The use of PSA for CaP screening is controversial and necessitates an open conversation between medical provider and patient regarding benefits/risks.
- Active surveillance is an important treatment option to consider for low-risk patients.
- Care must be taken when interpreting PSA levels in patients taking 5-α-reductase inhibitors.
PROSTATIC HYPERPLASIA, BENIGN (BPH)
Sara M. DeSpain, MD • Hannah P. Hornsby, MD

BASICS
- Benign prostatic hyperplasia (BPH) is due to proliferation of both the smooth muscle and epithelial cell lines of the prostate, which causes increased prostate volume and may lead to compression of the urethra and obstructive symptoms.
- Clinically presents with storage and/or voiding symptoms, which are collectively referred to as lower urinary tract symptoms (LUTS). These include difficulty initiating stream, frequency, or dysuria.
- Symptoms do not directly correlate to prostate volume. It is estimated that only half of all men with histologic evidence of BPH experience moderate to severe LUTS.
- Progression may result in upper and lower tract infections and may progress to direct bladder outlet obstruction and acute renal failure (ARF).

EPIDEMIOLOGY
Age related, nearly universal development in men.

Incidence
Incidence increases with age; estimates of prevalence vary from 70% to 90% by the age of 80 years (estimated at 8–20% by age 40 years).

ETIOLOGY AND PATHOPHYSIOLOGY
- Develops in prostatic periurethral or transition zone
- Hyperplastic nodules of stromal and epithelial components increase glandular components.
- Etiology is unknown.

RISK FACTORS
- Most significant risk factor is age.
- Increased risk with higher free prostate-specific antigen (PSA) levels, heart disease, and use of β-blockers
- Low androgen levels from cirrhosis/chronic alcoholism can reduce the risk of BPH.
- Obesity and lack of exercise can cause LUTS to be more significant.
- No evidence of increased or decreased risk with smoking, alcohol, or any dietary factors

GENERAL PREVENTION
- The disease appears to be part of the aging process.
- Symptoms can be managed through weight loss, regulation of fluid intake (especially in the evening), decreased intake of caffeine, and increased physical activity.

COMMONLY ASSOCIATED CONDITIONS
- LUTS
  - LUTS can be divided into two groups: filling/storage symptoms and voiding symptoms.
    - Filling/storage symptoms include frequency, nocturia, urgency, and urge incontinence.
    - Voiding symptoms include difficulty initiating stream, incomplete voiding, or weak stream.
CAN LEAD TO ACUTE OR CHRONIC OBSTRUCTIVE SYMPTOMS
- Sexual dysfunction, including erectile dysfunction (ED) and ejaculatory disorders
- LUTS can also be secondary to cardiovascular, respiratory, or renal disease (1).

DIAGNOSIS

HISTORY
- Evaluate symptom severity with the American Urological Society Symptom Index (AUA-SI) or the International Prostate Symptom Score (IPSS).
- Screen for other causes of symptoms such as infection, procedural history, or neurogenic causes. Evaluate for comorbid conditions, which may produce similar symptoms such as diabetes, congestive heart failure (CHF), or Parkinson disease.
- Review medication list, particularly diuretics and anticholinergic medications, as well as decongestants (increased sphincter tone), opiates (impaired autonomic function), or tricyclic antidepressants (anticholinergic effects).
- Review family history for BPH and prostate cancer.
- Screen for gross hematuria.
- IPSS scoring of LUTS (patient survey tracking severity) (2):
  - Questionnaire: Over the past month, how often have you:
    1. Had the sensation of not emptying your bladder completely after you finished urinating?
    2. Had to urinate again <2 hours after you finished urinating?
    3. Found you stopped and started again several times when you urinated?
    4. Found it difficult to postpone urination?
    5. Had a weak urinary stream?
    6. Had to push or strain to begin urination?
    7. Been up to urinate from the time you went to bed at night until the time you got up in the morning?
    8. How would you feel if you were to spend the rest of your life with your current symptoms?
  - Scoring of the questionnaire:
    o Questions 1 to 6: no symptoms = 0 points, 1 in 5 times = 1 point, less than half = 2 points, about half = 3 points, more than half = 4 points, most of the time = 5 points
    o Question 7: no occurrence = 0 points, 1 time = 1 point, 2 times = 2 points, 3 times = 3 points, 4 times = 4 points, and 5 times or more = 5 points
    o Question 8: 0 = delighted, 1 = pleased, 2 = mostly satisfied, 3 = mixed, 4 = mostly dissatisfied, 5 = unhappy, 6 = terrible
  - Symptoms are classified as mild (total score 0 to 7), moderate (total score 8 to 19), and severe (total score 20 to 35).
- Nocturia >2 times per night warrants a frequency/volume chart for 2 to 3 days to detect urinary patterns.

PHYSICAL EXAM
- Digital rectal exam (DRE) finding of symmetrically enlarged prostate, but size does not always correlate with symptoms.
- Signs of renal failure due to obstructive uropathy (edema, pallor, pruritus, ecchymosis, nutritional deficiencies)
If DRE is suggestive of prostate cancer, or if there is hematuria, recurrent infections, concern for stricture, or evidence of neurologic disease, then the patient should be referred to urology.

**DIFFERENTIAL DIAGNOSIS**

- **Obstructive**
  - Prostate cancer
  - Urethral stricture or valves
  - Bladder neck contracture (usually secondary to prostate surgery)
  - Inability of bladder neck or external sphincter to relax appropriately during voiding
- **Neurogenic**
  - Spinal cord injury or stroke
  - Parkinsonism
  - Multiple sclerosis
- **Medical**
  - Poorly controlled diabetes mellitus
  - CHF
- **Pharmacologic**
  - Diuretics
  - Decongestants
  - Anticholinergics
  - Opioids
  - Tricyclic antidepressants
- **Other:**
  - Bladder carcinoma
  - Overactive bladder
  - Nocturnal polyuria (>33% of the 24-hour urine volume occurs at night.)
  - Bladder calculi
  - UTI
  - Prostatitis
  - Urethritis/sexually transmitted infections
  - Obstructive sleep apnea (OSA) (nocturia)
  - Caffeine
  - Polyuria (either isolated nocturnal polyuria or 24-hour polyuria)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Urinalysis (UA) in all patients presenting with LUTS can help rule out other etiologies such as bladder/kidney stones, cancer, UTI, or urethral strictures.
- PSA (especially for men with a life expectancy of 10 years or more who would be surgical candidates if prostate cancer was identified)
- PSA levels also correlate with prostate volume, which can help guide treatment choice.
- With bladder cancer risk factors (smoking history or hematuria), obtain urine cytology and/or cystoscopy.
- If nocturia is the main concern, consider using a frequency volume chart for urine output.
- Sleep study if OSA or primary nocturnal polyuria is suspected
- Serum creatinine measurement is not recommended (AUA recommendation).
Follow-Up Tests & Special Considerations
- No further testing is recommended in uncomplicated LUTS; further testing if symptoms do not respond to medical management or if initial evaluation suggests underlying disease
- Uroflow: volume voided per unit time (Peak flow <10 mL/sec is abnormal.)
- Postvoid residual (PVR): either with catheterization or bladder ultrasound (>100 mL = incomplete emptying)
- Transrectal ultrasound: assessment of prostate gland size; not necessary in the routine evaluation
- Abdominal ultrasound: can demonstrate increased PVR or hydronephrosis; not necessary in the routine evaluation

Diagnostic Procedures/Other
- Pressure-flow studies (urine flow vs. voiding pressures) to determine etiology of symptoms
  - Obstructive pattern shows high voiding pressures with low-flow rate.
- Cystoscopy
  - Demonstrates presence, configuration, cause (stricture, stone), and site of obstructive tissue
  - May help determine therapeutic option
  - Not recommended in initial evaluation unless other factors, such as hematuria, are present

TREATMENT

GENERAL MEASURES
- Treatment ranges from watchful waiting to lifestyle modifications, medications, or surgical management.
- Mild symptoms (score of <7) or moderate symptoms (score 8 to 15) that are nonbothersome require no treatment. Reevaluate annually.
- For moderate to severe symptoms, try lifestyle interventions regulation of fluid intake, avoidance of alcohol and caffeine, exercise, diet, and eliminating/reducing contributing medications.
- Medical treatment requires interval follow-up of 2 to 4 weeks for α-blockers and 3 months for 5-α-reductase inhibitors until symptoms improved and then annually.
- Patients with complications including obstruction and urinary retention require bladder drainage.

MEDICATION
- Should be used as additive therapy; lifestyle modifications are still encouraged.
- Two main classes of medications: α-adrenergic antagonists and 5-α-reductase inhibitors
- The combination of these two medication classes is effective for long-term management of BPH and demonstrated large prostates.
  - α-Adrenergic antagonists
    - First-line option for moderate/severe and bothersome LUTS (2)[A]. Affect contraction of smooth muscle in the prostatic urethra and bladder neck. Show benefit over placebo. Typically take 2 to 4 weeks to show improvement. May affect blood pressure; require dose titration and blood pressure monitoring. AUA recommends alfuzosin (Uroxatral), doxazosin (Cardura), and tamsulosin (Flomax) because they are thought to be more selective and have less effect on blood pressure. Prazosin (Minipress) and
phenoxybenzamine (Dibenzyline) have insufficient evidence and are not recommended. Most common adverse effect is dizziness; may cause orthostatic hypotension.

- Doxazosin (Cardura): 1 to 8 mg/day PO; may delay the occurrence of acute urinary retention but does not decrease incidence
- Tamsulosin (Flomax): 0.4 to 0.8 mg/day PO. Typically requires 0.8mg/day dose for best results.
- Alfuzosin (Uroxatral): 10 mg/day PO
- Terazosin (Hytrin): Start at 1 mg PO daily at bedtime, max 20 mg daily.

  Contraindications:
  - Use caution in patients who are also using phosphodiesterase type 5 inhibitors for ED.
  - Do not use in men pursuing cataract surgery until they are postoperative due to the risk for perioperative floppy iris syndrome.

- 5-α-reductase inhibitors
  - Block conversion of testosterone to dihydrotestosterone, gradually reduce prostatic volume; most benefit when prostate volume exceeds 40 mL. Require 6 months to show clinical benefit. Two equally effective options:
    - Finasteride (Proscar): 5 mg/day PO
    - Dutasteride (Avodart): 0.5 mg/day PO
  - Should not be used in patients without evidence of enlarged prostates
  - Show reduced risk of acute urinary retention, less need for surgical intervention, and less overall incidence of prostate cancer
  - Used in patients with refractory hematuria after other causes have been ruled out
  - Side effects include decreased libido and ED.

**ALERT**
A PSA value in a patient taking a 5-α-reductase inhibitors will be artificially low by up to 50%.

- Combination therapy of α-blocker plus 5-α-reductase inhibitor is superior to monotherapy with an α-blocker only in men with evidence of enlarged prostates.
- Combination therapy is superior to monotherapy to prevent progression but increase risk of drug-related adverse events.
- Anticholinergic agents are appropriate for irritative LUTS without an elevated PVR. Options include solifenacin (VESIcare), tolterodine (Detrol LA), or oxybutynin ( Ditropan XL); should be avoided in patients with PVR >250 mL
- If patient also experiences ED, phosphodiesterase-5 inhibitors have been shown to have mild improvement of LUTS; can use tadalafil (Cialis): 5 mg/day PO but avoid use in combination with α-blockers or in those with creatinine clearance <30 mL/min

**Geriatric Considerations**
Use caution with anticholinergics, antihistamines, sympathomimetics, tricyclic antidepressants, and opioids.

**ISSUES FOR REFERRAL**
- Moderate or severe LUTS that does not respond to medical management
- BPH-related complications such as recurrent UTIs or hematuria, renal insufficiency, and urinary retention
- Abnormal PSA or prostate exam
- Any history of urethral trauma or stricture, or neurologic disease of the bladder/urinary system
SURGERY/OTHER PROCEDURES

- Indications for surgery:
  - Urinary retention due to prostatic obstruction, recurrent, no improvement with medications
  - Intractable symptoms due to prostatic obstruction AUA score >8 and symptoms
  - Obstructive uropathy (renal insufficiency)
  - Recurrent or persistent UTIs due to prostatic obstruction
  - Recurrent gross hematuria due to enlarged prostate
  - Bladder calculi
- Surgical procedures: TURP remains the gold standard of surgical procedures; however, for selected patient populations, there are other options available.
- Common complications of TURP:
  - Bleeding can be significant.
  - TURP syndrome: hyponatremia secondary to absorption of hypotonic irrigation fluid
  - Retrograde ejaculation
  - Urinary incontinence
- Other options include transurethral vaporization of the prostate (TUVP), transurethral microwave thermotherapy (TUMT) and transurethral incision of the prostate (TUIP). Open prostatectomy is more common when prostate exceeds 100 g. Transurethral laser ablation is an alternative option for patients on anticoagulants (3).

COMPLEMENTARY & ALTERNATIVE MEDICINE

Saw palmetto (Serenoa repens) has been thoroughly studied in a subject in Cochrane review and did not improve LUTS. Other agents including pygeum, Cernilton, and herbs with β-sitosterols have been studied less; however, no current evidence to support their use. Acupuncture failed to show improvement in LUTS in one clinical trial as well. There are no recommended complementary or alternative treatments for BPH (2)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Symptom index (IPSS) monitored every 3 to 12 months
- DRE yearly in patients who choose watchful waiting
- PSA yearly in patients who choose watchful waiting: should not be checked while patient is in retention, recently catheterized, or within a week of any surgical procedure to the prostate
- Consider monitoring PVR, if elevated.

DIET

Avoid large boluses of oral or IV fluids or alcohol intake; caffeine may exacerbate symptoms as well.

PATIENT EDUCATION

National Kidney and Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893; 301-468-6345

PROGNOSIS
Symptoms improve or stabilize in 70–80% of patients.
25% of men with LUTS will have persistent storage symptoms after prostatectomy.
Of men with BPH, 11–33% have occult prostate cancer.

COMPLICATIONS
- Urinary retention (acute or chronic)
- Bladder stones
- Prostatitis
- Hematuria

REFERENCES

ADDITIONAL READING

CODES
ICD10
- N40.0 Enlarged prostate without lower urinary tract symptoms
- N40.1 Enlarged prostate with lower urinary tract symptoms

CLINICAL PEARLS
- Although medical therapy has changed the management of BPH, it has only delayed the need for TURP by 10 to 15 years, not eliminated it.
- Urinary retention, obstructive uropathy, recurrent UTIs, elevated PSA, bladder calculi, hematuria, and failure of medical therapy are indications for surgical management of BPH.
PROSTATITIS
Elena Voronejskaia, MD • Robert Bonanno, MD

BASICS

DESCRIPTION
- Painful or inflammatory condition affecting the prostate gland with or without bacterial etiology, often characterized by urogenital pain, voiding symptoms, and/or sexual dysfunction
- Significant impact on quality of life
- <10% bacteria-proven infection
- National Institutes of Health’s classification
  - Class I: acute bacterial prostatitis: symptomatic with fever, perineal pain, dysuria, and obstructive symptoms; polymorphonuclear leukocytes (PMNL) and bacteria in urine
  - Class II: chronic bacterial prostatitis: symptomatic chronic or recurrent bacterial infection with pain and voiding disturbances; PMNL and bacteria in expressed prostatic secretions (EPS), or urine after prostate massage, or in semen
  - Class III: chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS)
    - Inflammatory (subtype IIIA): chronic symptoms with PMNL in EPS/urine after prostate massage or in semen
    - Noninflammatory (subtype IIIB): chronic symptoms without presence of PMNL in EPS/urine after prostate massage or in semen
  - Class IV: asymptomatic inflammatory prostatitis: incidental finding during prostate biopsy for infertility, cancer workup; presence of PMNL and/or bacteria in EPS/urine after prostatic massage or in semen
- System(s) affected: genitourinary, renal, reproductive

EPIDEMIOLOGY

Incidence
- Two million cases annually in the United States
- Bimodal peak 20–40 and >60 years old
- Chronic is more common in those >50 years
- Bacterial prostatitis occurs more frequently in patients with HIV.

Prevalence
- Affects approximately 8.2% of males
- Lifetime probability of diagnosis >25%
- Accounts for 8% of visits to urologists and 1% of visits to primary care physicians
- Percentage of cases by class: class I: <1%, class II: 5–10%, class III: 80–90%, class IV: 10%

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute bacterial prostatitis (NIH class I)
  - Likely, etiology from ascending urethral infection with intraprostatic reflux of infected urine into prostatic ducts, often associated with cystitis
  - Can occur after instrumentation of prostate
  - Usually, gram-negative bacteria (Escherichia coli [most common]; Proteus, Klebsiella, Serratia, and Enterobacter species; Pseudomonas aeruginosa)
- Rarely, gram-positive bacteria (Staphylococcus aureus, Streptococcus, and Enterococcus species)
- Confirmed staphylococcal prostatitis should warrant evaluation for hematogenous spread, including endovascular source.
- Atypical bacteria include Chlamydia trachomatis, Trichomonas vaginalis, Ureaplasma urealyticum, Mycobacterium tuberculosis, and fungal etiologies in immunocompromised hosts.
- Consider Neisseria gonorrhoeae or C. trachomatis in sexually active men <35 years.

**Chronic bacterial prostatitis (NIH class II)**
- Similar pathogens as discussed earlier
- Often occurs as recurrent episodes of infection by same organism
- Progression from acute to chronic prostatitis is poorly understood but could result from inadequate treatment of acute prostatitis or from bacterial biofilm production

**CP/CPPS (NIH class III)**
- Unclear etiology with no current data to support an infectious cause
- Inciting agent may cause inflammation or neurologic damage in or around the prostate and leads to pelvic floor neuromuscular and/or neuropathic pain.
- No correlation between histologic inflammation of prostate and presence or absence of symptoms
- Patients with chronic inflammation on histology have shorter time to symptomatic progression.

**RISK FACTORS**
- Urinary tract infections (including sexually transmitted infections)
- HIV infection
- Prostatic calculi
- Urethral stricture
- Urinary catheterization: indwelling, intermittent
- Genitourinary instrumentation, including prostate biopsy (especially in patients with prior quinolone intake), transurethral resection of prostate, cystoscopy
- Urinary retention
- Benign prostatic hypertrophy
- Unprotected sexual intercourse
- Prostate cancer

**GENERAL PREVENTION**
Antibiotic prophylaxis for genitourinary instrumentation and prostatic biopsy

**COMMONLY ASSOCIATED CONDITIONS**
- Benign prostatic hypertrophy
- Cystitis
- Urethritis
- Sexual dysfunction, including erectile dysfunction and premature ejaculation

**DIAGNOSIS**

**HISTORY**
• Acute prostatitis (class I):
  – Acutely ill with fever, chills, malaise
  – Low back pain, myalgias
  – Frequency, urgency, dysuria, nocturia
  – Prostatodynia, pelvic pain, perineal pain
  – Cloudy urine
  – Obstructive voiding symptoms: poor stream, hesitancy

• Chronic prostatitis (classes II and III) (symptoms vary from patient to patient and may include the following):
  – More insidious presentation than class I
  – Symptoms for 3 of 6 previous months
  – Low-grade fever (class II only)
  – Prostatodynia, perineal pain
  – Dysuria, frequency, urgency
  – Lower abdominal pain
  – Low back, testicular, and/or penile pain
  – Hematospermia
  – Sexual dysfunction/painful ejaculation

PHYSICAL EXAM
• Vital signs (Unstable vitals suggest sepsis.)
• Back exam (CVA tenderness)
• Abdominal exam (bladder distension)
• Prostate exam
  – NIH Class I: acute bacterial prostatitis: Prostate is very tender, warm, firm, and edematous.
  – NIH Class II: chronic bacterial prostatitis: Prostate is often normal but enlarged, tender, edematous, nodular prostate also encountered
  – NIH Class III: chronic prostatitis/chronic pelvic pain syndrome (CPPS): often normal prostate

ALERT
Avoid vigorous massage of the prostate in acute bacterial prostatitis; may induce iatrogenic bacteremia; safe if done gently

DIFFERENTIAL DIAGNOSIS
• Lower urinary tract infection
• Pyelonephritis
• Cystitis (bacterial, interstitial)
• Urethritis
• Prostatic abscess
• Acute/chronic urinary retention
• Benign prostatic hypertrophy malignancy (prostate, bladder)
• Obstructive calculi
• Foreign body

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Suspected acute prostatitis (NIH class I)
- Urinalysis, urine culture and sensitivity (1)[A]
- Complete blood count with differential, blood culture if immunocompromised or signs of SIRS/sepsis are present
- Prostate-specific antigen (PSA) is not recommended unless specific indications
- Imaging is optional (1)[A] and used as indicated to rule out complications (e.g., transrectal prostatic ultrasound [TRUS] or CT scan of abdomen to rule out abscess, pelvic ultrasound (US)/bladder scan if symptoms of urinary retention). Initial imaging of prostate is not recommended.
- Sexually transmitted infection (STI) testing in men <35 or >35 years old with high-risk sexual behavior

Suspected chronic bacterial prostatitis (NIH class II)
- Microbiological localization cultures of lower urinary tract (4-glass test or 2-glass pre- and post-massage urine culture)
- Semen cultures are not recommended.
- Transrectal prostatic ultrasound is not recommended unless there is a specific indication.
- Urodynamics studies are optional and could help to document obstruction/bladder problems.

Suspected CP/CPPS (NIH class III)
- Diagnosis of exclusion (especially to rule out urinary tract infection/STI with history/physical exam and appropriate laboratory investigation if indicated)
- 4-glass test or 2-glass pre- and post-massage test with urine microscopy considered optional (prostatic massage rarely and anecdotally associated with sepsis; proceed with caution)
- Urodynamics studies are optional and could be helpful to investigate obstructive symptoms
- Semen cultures are not recommended
- Cystoscopy may be indicated for select patients (i.e., with hematuria or obstructive symptoms refractory to treatment).
- Transrectal prostatic US is not recommended unless there is a specific indication.
- Serum PSA levels not recommended unless specific indications (e.g., abnormal DRE, > 45 years, family history of prostate cancer or risk factors)
- Psychological assessment is optional to address psychosocial factors.
- If hematuria present: urine cytology, cystoscopy, CT urography with or without contrast
- Urethral symptoms (dysuria, discharge, penile pain): urethral swab
- Concomitant abdominal pain: consider CT scan of abdomen
- Testicular pain: scrotal US
- Lumbar radiculopathy: MRI of spine

Follow-Up Tests & Special Considerations
- Failure to respond to initial antibiotic therapy: US, CT scan, or MRI to image prostate and urology referral
- TRUS, CT scan, or MRI if prostatic calculi, malignancy, or abscess is suspected
- Acute bacterial: Repeat urinalysis and/or culture if symptoms persist after appropriate course of treatment. Consider repeating urine culture 7 days after antibiotic therapy to ensure resolution of infection.
Diagnostic Procedures/Other

- Needle biopsy or aspiration for culture
- Urodynamic testing if obstructive symptoms present
- Cystoscopy (to investigate for bladder cancer, interstitial cystitis if hematuria or obstructive symptoms refractory to treatment present)

TREATMENT

GENERAL MEASURES

- NSAIDs for analgesia
- Alpha-1 blockers for lower urinary tract symptoms (obstructive/voiding symptoms
- Antipyretics/stool softeners
- Hydration
- Sitz baths to relieve pain and spasm
- Urinary drainage for urine retention
- Anxiolytics, antidepressants if anxiety and/or depression are present

MEDICATION

First Line

- Acute bacterial NIH class I (outpatient) (1)
  - Antimicrobial therapy is recommended (1)[A]
  - Fluoroquinolones are preferred 1st line agents
    - Fluoroquinolones: Ciprofloxacin 500 mg PO q12h or Levofloxacin 500–750 mg PO once daily
    - Trimethoprim-sulfamethoxazole 160/800 mg PO q12 hrs (consider local E. Coli resistance rates)
  - Duration of therapy is 2–4 weeks (up to 4–6 weeks recommended by some authorities).
  - If at risk for sexually transmitted infection (STI): ceftriaxone 250 mg IM for 1 dose (or Cefixime 400 mg PO one dose) plus doxycycline 100 mg PO q12h for 10 days
  - Alpha-1-blockers for symptomatic relief of lower urinary tract symptoms and NSAIDs for analgesia

- Acute bacterial NIH class I (inpatient) (1)
  - Urinary drainage (indwelling, intermittent or suprapubic catheterization)
  - Obtain both blood and urine cultures
  - Initial broad spectrum IV antibiotic therapy:
    - Broad spectrum penicillin with beta-lactamase inhibitor (Piperacillin-Tazobactam 3.375–4.5 g IV q6hrs) or IV fluoroquinolone (Ciprofloxacin 400 mg IV q12 hrs, Levofloxacin 500–750 mg IV q24 hrs) or 3rd generation cephalosporin (Ceftriaxone 1–2 g IV q24 hrs, Cefotaxime 2 g IV q4–8 hrs, Ceftazidime 2 g IV q8 hrs)
    - Consider adding IV amnioglycoside to any of above antibiotics if severely ill.
    - Consider IV carbapenem if a history of recent prostatic instrumentation or other risk factors for bacterial resistance (especially resistant Enterobacteriaceae and Pseudomonal species)
    - De-escalate to oral regimen pending blood/urine culture results and with clinical improvement for additional 2–4 weeks of therapy.

- Chronic bacterial NIH class II (1)
– Antimicrobial therapy (1)[A]
  – Fluoroquinolones are preferred 1st line agents (Ciprofloxacin 500 mg PO q12h or Levofloxacin 500–750 mg PO once daily for 4–6 weeks) with trimethoprim-sulfamethoxazole (160/800 mg PO q12 hrs for 8–12 weeks) a suitable alternative.
  – Therapy with macrolide (Azithromycin) may help to eradicate intracellular pathogens (chlamydia).
  – Refractory cases: can consider intermittent antimicrobial treatment of acute symptomatic episodes (cystitis), low dose antimicrobial suppression, radical TURP, or open prostatectomy if all options failed
  – Alpha-blockers combined with antimicrobial therapy reduces high recurrence rate and are optimal for patients with obstructive symptoms

• CP/CPPS NIH class III (2)
  – Heterogeneous condition with no universally effective treatment
  – Treatment choice is patient-centered, focusing on symptoms relief of four domains: pain, lower urinary tract symptoms (LUTS), psychological stress, and sexual dysfunction.
  – Alpha-1 blockers not be recommended as first line therapy however more benefit in Alpha-1 blocker naive men with recent onset of symptoms especially in men with voiding symptoms (1)[C]
  – NSAIDs are not recommended as primary therapy unless part of multimodal therapy regimen (1)[C].
  – Antimicrobials cannot be recommended for men with longstanding and previously treated CP/CPPS

ISSUES FOR REFERRAL
Urology referral if antibiotic treatment fails, symptoms persist (especially obstructive voiding symptoms), hematuria, elevated PSA, or for surgical drainage if an abscess persists after ≥1 week of therapy

ADDITIONAL THERAPIES
• Psychotherapy (ideally including cognitive-behavioral therapy [CBT]) in cases of psychosocial stressors or sexual dysfunction
• Pudendal nerve block or neurolysis could be beneficial if symptoms are secondary to pudendal nerve entrapment.

SURGERY/OTHER PROCEDURES
Surgical resection may be considered for refractory cases of recurrent bacterial prostatitis or to drain an abscess. For CP/CPPS Class III, procedures such as balloon dilation, neodymium:Yag laser, transurethral needle ablation, microwave hyperthermia, thermotherapy are not recommended at this time. For CP/CPPS Class III, radical transurethral resection or total prostatectomy is not recommended.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Chronic Prostatitis/CPPS Class III: Acupuncture and extracorporeal shockwave therapy have best evidence of decrease in prostatitis symptoms without adverse effects.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Proven or suspected abscess
• Risk factors for resistance (recent prostatic instrumentation or recent fluoroquinolone use)
- Immunocompromised

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Negative urine culture at 7 days predictive of cure after completion of treatment course
- Consider prostatic abscess in patients who do not respond well to therapy.

**Patient Monitoring**
NIH-CPSI: 9 questions, which can be used to evaluate severity of patient symptoms and response to treatment within three domains:
- Pain
- Urinary symptoms
- Quality of life

**PROGNOSIS**
- Fever and dysuria usually resolve in 2 to 6 days.
- Acute infection usually improves in 3 to 4 weeks.
- Course of chronic prostatitis is often prolonged and difficult to cure; 55–97% cure rate depending on population and drug used
- 20% have reinfection or persistent infection.

**COMPLICATIONS**
- Prostatic abscess (common in HIV infected)
- Pyelonephritis
- Gram-negative sepsis, bacteremia
- Urinary retention
- Epididymitis
- Infertility
- Chronic bacterial prostatitis (following acute prostatitis)
- Metastatic infection (spinal, sacroiliac)

**REFERENCES**

**ADDITIONAL READING**
- **Prostate Cancer; Prostatic Hyperplasia, Benign (BPH); Urinary Tract Infection (UTI) in Males**
- **Algorithm:** Hematuria

**CODES**

**ICD10**
- N41.9 Inflammatory disease of prostate, unspecified
- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis

**CLINICAL PEARLS**
- Prostatic massage is contraindicated in acute prostatitis.
- Fluoroquinolones are recommended first-line antibiotic for bacterial prostatitis, both acute and chronic.
- At least 14 to 30 days of antibiotic therapy is required for acute prostatitis; longer for chronic bacterial prostatitis
- Antibiotic therapy is not proven to be effective in CP/CPPS (class III).
PROTEIN C DEFICIENCY
James E. Hougas III, MD, FAAFP • Donald J. Fahey-Ahrndt, MD

BASICS

DESCRIPTION
● Protein C is a vitamin K–dependent factor synthesized, in an inactive form, by the liver.
● Activated protein C inhibits generation of thrombin by inactivating factors Va and VIIIa, using protein S as a cofactor.
● Deficiency in protein C activity therefore leads to a prothrombotic state.
● System(s) affected: cardiovascular, pulmonary, integumentary, hematologic, and immunologic

EPIDEMIOLOGY

Prevalence
● 0.3% of the general population
● 3–5% of persons with venous thromboembolism (VTE)
● Mean age of first thrombosis is 45 years.
● There is no known gender predominance.

ETIOLOGY AND PATHOPHYSIOLOGY
● Protein C deficiency (PCD) can be inherited or acquired.
● Genetic mutations can lead to two types of PCD; however, the distinction between the two is clinically irrelevant.
  – Type I (most common) results in the reduction of protein C levels.
  – Type II results in a decreased functionality, despite having normal levels of protein C.
● Acquired PCD can occur in many disease states such as:
  – Liver disease
  – Disseminated intravascular coagulation (DIC)
  – Severe infections (especially meningococcemia)
  – Autoantibody inhibitors directed toward protein C
  – Cancer and chemotherapy (i.e., L-asparaginase, 5-FU, methotrexate, and cyclophosphamide)
  – Initial use of vitamin K antagonists (warfarin)
  – Vitamin K deficiency (malnutrition or malabsorption of fat-soluble vitamins)

Genetics
● Autosomal dominant inheritance pattern with incomplete penetrance
● At least 160 genetic mutations have been described in the protein C gene that can lead to a functional deficiency.
● Heterozygous patients often have mild or asymptomatic disease.
● Homozygous patients, or those with another coexisting genetic thrombophilia, often have more severe disease.
● Additionally, mutations in other genes (GCKR, EDEM2, BAZ1B, etc.) are associated with variability in the levels of protein C expression in the general population, although their clinical significance is currently unknown.
● Patients with PCD who start warfarin without concomitant heparin are at increased risk of
developing warfarin-induced skin necrosis (WISN). This is thought to be due to the shorter half-life of protein C (5 to 8 hours) compared to other vitamin K–dependent clotting factors. However, not all patients who develop WISN have PCD (1).

**ALERT**
The prevention of warfarin necrosis has been achieved by avoiding loading doses of warfarin and the use of heparin bridging. Screening all patients for inherited or acquired forms of PCD prior to initiating warfarin is not cost-effective nor prognostic because many patients with documented deficiency do not progress to WISN (1)[C].

**GENERAL PREVENTION**
Because PCD is usually a congenital disease, there are no preventive measures.

**COMMONLY ASSOCIATED CONDITIONS**
- VTE at any site, often spontaneous
- Arterial thrombosis is rare, and a causative relationship has not been clearly demonstrated.
- Homozygosity can be associated with catastrophic thrombotic complications at birth (e.g., purpura fulminans).
- Recurrent pregnancy losses

**DIAGNOSIS**

**HISTORY**
- Recurrent VTE
- VTE at <40 years of age
- Thrombosis in unusual locations (e.g., mesentery, sagittal sinus, portal vein)
- Family history of thrombosis or spontaneous abortion
- Often has other usual risk factors for provoked VTE

**PHYSICAL EXAM**
Normal

**DIFFERENTIAL DIAGNOSIS**
- Factor V Leiden
- Protein S deficiency
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Hyperhomocysteinemia
- Prothrombin 20210 mutation
- Elevated factor VIII, IX, or XI levels
- Antiphospholipid antibody syndrome
- DIC
- Heparin-induced thrombocytopenia (HIT)

**DIAGNOSTIC TESTS & INTERPRETATION**
Initial Tests (lab, imaging)
Initial evaluation of a new clot in patients should include a CBC with peripheral smear, INR, aPTT, hepatic and renal function tests as well as appropriate imaging.

- Testing for heritable causes of thrombophilia in unselected patients presenting with a first-time VTE (provoked or unprovoked) is not indicated (2),(3)[C].
- Consider screening for antiphospholipid syndrome rather than other thrombophilia (PCD) for women with recurrent early pregnancy loss (three losses prior to 10 weeks’ gestation) (4)[B].

**Follow-Up Tests & Special Considerations**

- Testing for heritable or acquired thrombophilia is suggested in the following circumstances (5) [C]:
  - First episode of VTE and patient age <40 years
  - Recurrent VTE regardless of the presence of risk factors
  - Patients with VTE at unusual sites
- Testing for PCD should be considered in patients with history of WISN (3)[C].
- Testing for protein C and S deficiencies should be done urgently in neonates and children suspected to have purpura fulminans (2,3)[B].
- Testing for hereditary thrombophilia should only be considered in asymptomatic first-degree relatives of those with proven hereditary thrombophilia if they are female, of childbearing age, and have no history of prior pregnancy complications (3,4)[C].
- When ordering additional testing for hereditary or acquired thrombophilia, the following conditions should be considered (3)[C]:
  - Antiphospholipid antibody syndrome
  - Antithrombin III deficiency
  - Factor V Leiden
  - PCD
  - Protein S deficiency
  - Prothrombin G20210A
- Testing for PCD is done using two separate lab tests:
  - An immunoassay for a quantitative assessment of protein C levels
  - A functional activity assay using a snake venom protease to activate protein C

**Test Interpretation**

- Drugs that may alter lab results
  - Oral contraceptives can raise protein C levels.
  - Warfarin reduces protein C levels and should be discontinued 2 to 3 weeks before reliable testing.
- Disorders that may alter lab results
  - Liver disease reduces protein C levels.

**ALERT**

Acute thrombosis can lower protein C levels. Repeat confirmatory test of low protein C level at a separate time is advisable. If a normal level of protein C is obtained at presentation, then deficiency can be excluded.

**TREATMENT**

Treat active thrombosis; follow-up
GENERAL MEASURES

- Individuals with PCD should be educated regarding signs and symptoms of VTE.
- Women with any of the following history should avoid estradiol-containing contraceptives and hormone replacement therapy during menopause (3)[A]:
  - Diagnoses of PCD
  - First-degree relative with PCD
  - First-degree relative with VTE at age <50 years
- Women may use progestin-only hormonal contraception options.
- Routine anticoagulation for asymptomatic patients with PCD is not recommended (4)[C].
- Anticoagulation is recommended for at least 3 months in patients with inherited thrombophilia following their first VTE (2,5)[B].
  - There is some argument for indefinite anticoagulation; however, data are limited (3)[C].
  - Shared decision making should be used to discuss duration of therapy beyond 3 months (3)[C].
- Indefinite anticoagulation is indicated for patients with recurrent VTE (4)[A].
- Treat VTE as an outpatient when possible if clinically stable (4)[B].
- Severe congenital PCD may be treated with protein C concentrates.

Pregnancy Considerations

- Heparin-based products should be used during pregnancy when therapeutic or prophylactic treatment of VTE is needed.
- For pregnant women with known PCD but no personal history of VTE or additional thrombotic risk factors (i.e., family history of VTE in first-degree relative <50 years of age, obesity, prolonged immobility), antepartum and postpartum clinical monitoring is recommended over prophylactic therapy (5)[C].
- For pregnant women with known PCD, no personal history of VTE but with an additional thrombotic risk factor, antepartum surveillance is recommended with postpartum prophylactic therapy for 6 weeks of either prophylactic or intermediate dose (5)[C].
- For pregnant women with known PCD and previous VTE, it is recommended to give postpartum preventative therapy with either prophylactic or intermediate-dose LMWH. This could also be given antepartum versus surveillance at the provider’s discretion (5)[C].

MEDICATION

First Line

- LMWH (4)[A]: initially started with warfarin for a minimum of 5 days and two consecutive INRs between 2 and 3 to bridge. Additionally, LMWH may be started 5 to 10 days prior to starting dabigatran or edoxaban.
  - Enoxaparin (Lovenox) 1 mg/kg SC BID or 1.5 mg/kg/day SC
  - Tinzaparin (Innohep): 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 U/kg/day
- Novel oral anticoagulants (NOACs):
  - Rivaroxaban (Xarelto) 15 mg PO BID with food for 21 days and then 20 mg PO QD with food
  - Apixaban (Eliquis) 10 mg PO BID for 7 days and then 5 mg PO BID
  - Dabigatran (Pradaxa) 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
  - Edoxaban (Savaysa) 60 mg PO QD (after 5 to 10 days of parenteral anticoagulation)
- Oral vitamin K antagonist:
– Warfarin (Coumadin) titrated to an INR of 2 to 3 (4)[A]

- Factor Xa inhibitors:
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min

- Contraindications
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.

- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Monitor kidney function, drug–drug interactions, and CBC, including platelets (concern for HIT).

Second Line
- Heparin 80 U/kg IV bolus followed by 18 U/kg/hr; adjust dose depending on PPT.
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, and for outpatients, unfractionated heparin can be given at 333 U/kg and then 250 U/kg SC, without monitoring (4)[C].

ISSUES FOR REFERRAL
Patients with suspected PCD should be referred to a hematologist.

SURGERY/OTHER PROCEDURES
- Anticoagulation may be held for surgical interventions.
- In patients with acute proximal DVT of the lower extremity and an absolute contraindication to anticoagulation, inferior vena cava (IVC) filters are recommended; otherwise, the use of an IVC filter in addition to anticoagulants is not recommended (4)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Life-threatening VTE
- Significant bleeding while on anticoagulant therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Warfarin requires periodic monitoring of the INR to maintain a range of 2 to 3 (monthly, after initial stabilization).
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in these patients.

DIET
Unrestricted (except if on warfarin—avoid varying diet with foods that have significant amounts of vitamin K)

PATIENT EDUCATION
- Patients should be educated about signs and symptoms of VTE as well as the use of oral anticoagulant therapy if taking such.
• Avoid NSAIDs while on warfarin.
• Avoid OCPs because they increase risk of thrombosis.

PROGNOSIS
When compared with normal individuals, persons with PCD have normal life spans.

COMPLICATIONS
Primary or recurrent VTE

REFERENCES

CODES
ICD10
D68.59 Other primary thrombophilia

CLINICAL PEARLS
• Activated protein C inhibits generation of thrombin by inactivating factors Va and VIIIa, using protein S as a cofactor.
• Deficiency in protein C activity therefore leads to a prothrombotic state.
• Testing for heritable causes of thrombophilia in unselected patients presenting with a first episode of VTE (provoked or unprovoked) is not indicated.
• Screening, and therefore prophylactic treatment, of asymptomatic family members is not justified with the possible exception of females of childbearing age with no previous history of pregnancy complications.
• Asymptomatic patients with PCD do not need prophylactic anticoagulation because the risk of thrombosis is low.
• Patients with PCD presenting with first-time VTE should be anticoagulated for at least 3 months. Other risk factors and shared decision making should be used to determine if anticoagulation should be used for a longer duration.
• Recurrent VTE is an indication for indefinite anticoagulation.
PROTEIN S DEFICIENCY
Thuy Thanh Thi Le, DO ● Boris Calderon, DO

BASICS

DESCRIPTION
- Protein S is a vitamin K–dependent glycoprotein, produced mainly in the liver that acts as a cofactor for protein C. It is also produced by megakaryocytes and endothelial cells.
- Protein C becomes activated when thrombin binds to the endothelial receptor, thrombomodulin.
- Activated protein C, with protein S (a cofactor), inactivates clotting factors Va and VIIIa enhancing fibrinolysis.
- Protein S is also able to directly inhibit factors Va, VIIa, and Xa independently of activated protein C.
- Protein S deficiency is a congenital thrombophilia, which increases the risk of thromboembolism.
- It primarily affects the venous system.
- System(s) affected: cardiovascular, hematologic/immunologic, pulmonary

EPIDEMIOLOGY

Incidence
- Mean age of first thrombosis: 2nd decade
- Predominant sex: male = female

Prevalence
- ~0.2% of general population
- Found in ~1% of persons with venous thrombosis embolism (VTE)

ETIOLOGY AND PATHOPHYSIOLOGY

- It is an autosomal dominant disease.
- Only the free form of protein S (30–40%) acts as a cofactor for activated protein C. Protein S reversibly binds to the C4b protein, which leads to conditions in which free protein S is low, but total protein S is normal. These individuals are prone to thrombosis.
- Conditions with reduced protein S: pregnancy, oral contraceptives, warfarin, disseminated intravascular coagulation (DIC), liver disease, nephrotic syndrome, HIV, L-asparaginase chemotherapy, acute thrombosis, and acute varicella-zoster virus infection

Genetics
- Is due to mutations in the PROS1 gene on chromosome 3. Most individuals are heterozygous.
- Heterozygotes have an odds ratio (OR) of VTE of 1.6 to 11.5.
- Homozygosity or compound heterozygosity, if untreated, is usually incompatible with adult life.
- Homozygotes can have a fulminant thrombotic event in infancy, termed neonatal purpura fulminans.

RISK FACTORS
Oral contraceptives, pregnancy, and the use of HRT increase the risk of VTE in patients with protein S deficiency (1)[A]. Patients with protein S deficiency and other prothrombotic states have further increased rate of thrombosis (1)[A].

Arterial thrombosis is more frequent in patients with protein S deficiency who smoke. Patients heterozygous for protein S deficiency who are initiated on warfarin without concomitant heparin can develop warfarin-induced skin necrosis because the half-life of other vitamin K–dependent clotting factors (e.g., prothrombin, factor IX, factor X) is much longer than the anticoagulant protein S (4 to 8 hours), leading to a transient hypercoagulable state when protein S becomes depleted. These patients develop extremely low levels of protein S and develop necrosis of the skin over central areas of the body such as the breast, abdomen, buttocks, and genitalia (1)[A].

**Pregnancy Considerations**
Increased thrombotic risk and pregnancy losses

**GENERAL PREVENTION**
There are no preventive measures.

**COMMONLY ASSOCIATED CONDITIONS**
- Deep and superficial VTE, often unprovoked
- Up to 50% of homozygotes will have thrombosis.
- Homozygosity is associated with catastrophic thrombotic complications at birth: neonatal purpura fulminans.
- Sites of thrombosis can be unusual, including the mesentery, cerebral veins, and axillary veins.
- Arterial thrombosis is rare but reported in several case reports.
- Skin necrosis in patients treated with warfarin
- Recurrent pregnancy losses (2)

**DIAGNOSIS**

**HISTORY**
Inherited thrombophilias should be suspected in:
- Unprovoked VTE at age <50 years
- VTE with a strong family history of VTE or known familial protein S deficiency
- VTE in unusual sites as mesenteric or cerebral vein
- Recurrent VTE

**PHYSICAL EXAM**
Normal

**DIFFERENTIAL DIAGNOSIS**
Other inherited thrombophilias:
- Factor V Leiden (most common; usually in Caucasians)
- Protein C deficiency (in Caucasians)
- Antithrombin deficiency
- Dysfibrinogenemia
Dysplasminogenemia
Homocystinemia
Prothrombin G20210A mutation
Elevated factor VIII levels
Acquired VTE risk factors: surgery, immobility, cancer, myeloproliferative neoplasms, trauma, antiphospholipid syndrome, paroxysmal nocturnal hemoglobinuria, pregnancy, hormone replacement therapy, postpartum, DIC

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- For evaluation of new clot in a patient at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, anticardiolipin antibody, anti-β2-glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A
- Immunoassay for quantitative assessment of total and free protein S levels
- Protein S activity assay (mainly after obtaining activated protein C resistance)
- Disorders that may alter lab results: acute thrombosis, vitamin K antagonists (VKA), any acute illness response, liver disease, and pregnancy—reduce protein S levels. Direct oral anticoagulants affect protein S activity assay.
- Heparin and low-weight heparin do not alter lab results.
- Total protein S levels are markedly decreased in newborns and young infants; use age-adjusted norms.

**TREATMENT**

**GENERAL MEASURES**
- Routine anticoagulation for asymptomatic patients with protein S deficiency is not recommended.
- Antithrombotic therapy recommendations for patients with protein S deficiency can be guided by antithrombotic therapy for VTE disease guidelines.
- Patients with unprovoked VTE and who have a low or moderate bleeding risk are suggested to receive extended anticoagulant therapy (no scheduled stop date) over 3 months of therapy (1) [B],(3), and those who have a high bleeding risk are recommended to receive 3 months of anticoagulant therapy (3,4)[B].
- Patients with a second unprovoked VTE and who have a low to moderate bleeding risk are recommended to receive extended anticoagulant therapy over 3 months (3,4)[B]; those who have high bleeding risk are suggested to receive 3 months of anticoagulant therapy (1)[B],(3).
- Patients with VTE and no history of cancer are suggested to receive dabigatran, rivaroxaban, apixaban, or edoxaban over VKA therapy as long-term (first 3 months) anticoagulant therapy; VKA therapy over low-molecular-weight heparin (LMWH) (3)
- Patients with VTE and active cancer are suggested to receive LMWH, rivaroxaban, or edoxaban for long-term anticoagulation (5). It is recommended that these patients receive extended anticoagulant therapy (3).
- Treatment of thrombosis with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure.
- Treat as outpatient, if possible.
- Prophylaxis should be considered in risk situations such as surgery, immobility or postpartum, especially in patients with family history.
- The role of family screening for protein S deficiency is unclear because most patients with this mutation do not have thrombosis. Screening should be considered for women considering oral contraceptives or pregnancy and who have a family history of protein S deficiency (6)(B).

**MEDICATION**

- **LMWH**
  - Enoxaparin (Lovenox) 1 mg/kg SC BID
  - Alternatively, 1.5 mg/kg/day SC
  - Tinzaparin (Innohep) 175 anti-Xa U/kg/day SC
  - Dalteparin (Fragmin) 200 U/kg/day SC divided QD–BID
- **Factor Xa inhibitor**
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min
- **Novel oral anticoagulants (NOACs):**
  - Dabigatran 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
  - Rivaroxaban 15 mg PO BID for 21 days and then 20 mg PO QD
  - Apixaban 10 mg PO BID for 7 days and then 5 mg PO BID
  - Edoxaban: person weighs ≤60 kg: 30 mg PO QD OR >60 kg: 60 mg PO QD (after 5 to 10 days of parenteral anticoagulation)
- **Oral anticoagulant: warfarin (Coumadin):** 2 to 5 mg PO QD then adjusted to an INR of 2 to 3. LMWH initially for a minimum of 5 days and two consecutive INRs between 2 and 3, at which time it can be stopped; contraindications
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with a prior history of warfarin-induced skin necrosis.
- **Precautions**
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections.
  - Periodically, check stool and urine for occult blood; monitor CBC, including platelets.
  - Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, and buttocks)
  - LMWH: Adjust dose in renal insufficiency.
- **Significant possible interactions**
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfonpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

**ISSUES FOR REFERRAL**

- Patients with suspected protein S deficiency should be seen by a hematologist.
Screening and prophylactic treatment of asymptomatic family members is not justified (7).

SURGERY/OTHER PROCEDURES
- Anticoagulation must be held for surgical interventions.
- For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation. IVC filter is only recommended in case of contraindication to anticoagulation (3)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Life-threatening VTE
- Significant bleeding while on anticoagulant therapy
- Look for signs of bleeding while on anticoagulation therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Warfarin requires periodic (monthly after initial stabilization) monitoring of the INR.
- Periodic measurement of INR to maintain a range of 2 to 3
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in some cases, such as overweight and borderline renal failure.

DIET
Unrestricted

PATIENT EDUCATION
- Patients should be educated about use of oral anticoagulant therapy if taking such.
- Patients undergoing warfarin therapy should avoid drinking alcohol on a daily basis.
- Avoid NSAIDs while on warfarin.

PROGNOSIS
- Persons with protein S deficiency have normal lifespan.
- By age 45 years, 50% of the people heterozygous for protein S deficiency will have VT; half will be spontaneous.

COMPLICATIONS
Recurrent thrombosis (requires indefinite anticoagulation)

REFERENCES

CODES

ICD10
D68.59 Other primary thrombophilia

CLINICAL PEARLS

- Asymptomatic patients with protein S deficiency do not require prophylactic anticoagulation because the risk of thrombosis is low; asymptomatic patients do not require anticoagulation.
- Patients with protein S deficiency and DVT should be anticoagulated for at least 6 months, especially if first episode.
PROTEINURIA
Lovella Duru Kanu, MD

BASICS

DESCRIPTION
Urinary protein excretion of >150 mg/day
- Nephrotic-range proteinuria: urinary protein excretion of >3.5 g/day; also called heavy proteinuria
- Three pathologic types:
  - Glomerular proteinuria: increased permeability of proteins across glomerular capillary membrane
  - Tubular proteinuria: decreased proximal tubular reabsorption of proteins
  - Overflow proteinuria: increased production of low-molecular-weight proteins

Pediatric Considerations
- Proteinuria: Normal is daily excretion of up to 100 mg/m² (body surface area).
- Nephrotic-range proteinuria: daily excretion of >1,000 mg/m² (body surface area)

Pregnancy Considerations
- Proteinuria in pregnancy beyond 20 weeks’ gestation is a hallmark of preeclampsia/eclampsia and demands further workup.
- Proteinuria in pregnancy before 20 weeks’ gestation is suggestive of underlying renal disease.

ETIOLOGY AND PATHOPHYSIOLOGY
- Glomerular proteinuria: increased filtration/larger proteins (albumin) due to the following:
  - Increased size of glomerular basement membrane pores and
  - Loss of proteoglycan negative charge barrier
- Tubular proteinuria: Tubulointerstitial disease prevents proximal tubular reabsorption of smaller proteins (β₂-microglobulin, immunoglobulin [Ig] light chains, retinol-binding protein, amino acids).
- Overflow proteinuria: proximal tubular reabsorption overwhelmed by increased production of smaller proteins
- Glomerular proteinuria
  - Primary glomerulonephropathy
    - Minimal-change disease
    - Idiopathic/primary membranous glomerulonephritis
    - Focal segmental glomerulonephritis
    - Membranoproliferative glomerulonephritis
    - IgA nephropathy
  - Secondary glomerulonephropathy
    - Diabetic nephropathy
    - Autoimmune/collagen vascular disorders (e.g., lupus nephritis, Goodpasture syndrome)
    - Amyloidosis
    - Preeclampsia
Infection (HIV, hepatitis B and C, poststreptococcal, endocarditis, syphilis, malaria)
- Malignancy (GI, lung, lymphoma)
- Renal transplant rejection
- Structural (reflux nephropathy, polycystic kidney disease)
- Drug-induced (NSAIDs, penicillamine, lithium, heavy metals, gold, heroin)

- Tubular proteinuria
  - Hypertensive nephrosclerosis
  - Tubulointerstitial disease (uric acid nephropathy, hypersensitivity, interstitial nephritis, Fanconi syndrome, heavy metals, sickle cell disease, NSAIDs, antibiotics)
  - Acute tubular necrosis
- Overflow proteinuria
  - Multiple myeloma (light chains; also tubulotoxic)
  - Hemoglobinuria
  - Myoglobinuria (in rhabdomyolysis)
  - Lysozyme (in acute monocytic leukemia)
- Benign proteinuria
  - Functional (fever, exercise, cold exposure, stress, CHF)
  - Idiopathic transient
  - Orthostasis (postural)

**RISK FACTORS**
- Hypertension
- Diabetes
- Obesity
- Strenuous exercise
- CHF
- UTI
- Fever

**Genetics**
No known genetic pattern

**GENERAL PREVENTION**
Control of weight, BP, and blood glucose reduces the risk of proteinuria.

**COMMONLY ASSOCIATED CONDITIONS**
- Hypertension (common)
- Diabetes mellitus (DM) (common)
- Preeclampsia (common)
- Multiple myeloma (rare)

**DIAGNOSIS**

**HISTORY**
- Frothy/foamy urine
- Change in urine output
- Blood- or cola-colored urine
Recent weight change
Swelling
Rule out systemic illness: diabetes, heart failure, autoimmune, poststreptococcal infection.

**PHYSICAL EXAM**
- BP
- Weight
- Peripheral edema
- Periorbital/facial edema
- Ascites
- Palpation of kidneys
- Check lungs, heart for signs of CHF.

**DIFFERENTIAL DIAGNOSIS**
Includes all causes listed under “Etiology and Pathophysiology”

**DIAGNOSTIC TESTS & INTERPRETATION**
Screening for proteinuria is not cost-effective unless directed at groups with hypertension/diabetes, older persons, and so forth.

**Initial Tests (lab, imaging)**
- Urinalysis (UA) quantitatively estimates proteinuria:
  - Only sensitive to albumin; will not detect smaller proteins of overflow/tubular etiologies
  - False-positive finding if urine pH >7, highly concentrated (specific gravity [SG] >1.015), gross hematuria, mucus, semen, leukocytes, iodinated contrast agents, penicillin analogues, sulfonamide metabolites
  - False-negative finding if urine is dilute (SG 1.005), albumin excretion <20 to 30 mg/dL, protein is nonalbumin
  - Sensitivity, 32–46%; specificity, 97–100%
  - Also can perform sulfosalicylic acid test to detect nonalbumin protein
- If UA positive, perform urine microscopy. Refer to nephrologist if positive for signs of glomerular disease.
- If UA shows trace to 2+ protein, rule out transient proteinuria with repeat UA at another visit:
  - More common than persistent proteinuria
  - Causes include exercise, fever, CHF, UTI, and cold exposure.
  - Reassure patient that transient proteinuria is benign and requires no further workup.
- If initial UA shows 3+ to 4+ protein or repeat UA is positive, measure creatinine clearance and quantify proteinuria with 24-hour urine collection (gold standard) or spot urine protein-to-creatinine (P/C) ratio (acceptable practice) ([1][A]):
  - Numerical P/C ratios correlate with total protein excreted in grams per day (i.e., ratio of 0.2 correlates with 0.2 g during a 24-hour collection).
  - Patients age <30 years with 24-hour urine excretion of <2 g/day and normal creatinine clearance should be tested for orthostatic proteinuria:
    - Benign condition is present in 2–5% of adolescents.
    - Diagnosed with a normal urine P/C ratio in first morning void and an elevated urine P/C ratio in a second specimen taken after standing for several hours
- If protein excretion >2 g/day, consider nephrology referral and begin workup for systemic/renal disease.
Patients with persistent proteinuria not explained by orthostatic changes should undergo renal ultrasound to rule out structural abnormalities (e.g., reflux nephropathy, polycystic kidney).

**Follow-Up Tests & Special Considerations**
Renal/systemic disease workup can include the following:
- CBC, ferritin, ESR, serum iron
- Electrolytes, LFTs
- Lipid profile (ideally, fasting)
- Prothrombin time/international normalized ratio
- Anti-phospholipase A2 receptor antibody: positive in ~70% of primary membranous nephropathy
- Antinuclear antibodies: elevated in lupus
- Antistreptolysin O titer: elevated after streptococcal glomerulonephritis
- Complement C3/C4: low in most glomerulonephritis
- HIV, syphilis, and hepatitis serologies: all associated with glomerular proteinuria
- Serum and urine protein electrophoresis: abnormal in multiple myeloma
- Blood glucose: elevated in diabetes
- All patients with diabetes should be screened for microalbuminuria.
- Patients with nephrotic-range proteinuria are at increased risk for hypercholesterolemia and thromboembolic events (~25% of adult patients) with highest risk in membranous nephropathy. Optimal duration of prophylactic anticoagulation is unknown but may extend for the duration of the nephrotic state (2).
- Proteinuric pregnant patients beyond 20 weeks’ gestation should be examined for other signs/symptoms of preeclampsia (e.g., hypertension, thrombocytopenia, elevated liver transaminases).

**TREATMENT**
- BP goal for both diabetic and nondiabetic adults is ≤140/90 mm Hg (3)[C].
- Proteinuria goal is <0.5 g/day (4)[A].

**GENERAL MEASURES**
- Limit protein intake to 0.8 g/kg/day in adults with DM or without DM and glomerular filtration rate (GFR) <30 mL/min/1.73 m². Soy protein may be renoprotective. Monitor protein intake with 24-hour urine urea excretion (4)[A].
- Limit sodium chloride intake to <2 g/day to optimize antiproteinuric medications (3)[B]. Effect on BP is further protective (4)[A].
- Limit fluid intake for urine output goal of <2 L/day. Larger urine volumes are associated with increased proteinuria and later GFR decline (4)[B].
- Smoking cessation: Smoking is associated with increased proteinuria and faster kidney disease progression (4)[B].
- Encourage supine posture (up to 50% reduction vs. upright) (4)[B].
- Discourage severe exertion (4)[B].
- Encourage weight loss (4)[B].

**MEDICATION**
ACE inhibitors: first choice; use maximally tolerated doses; use even if normotensive (4)[A].
Angiotensin receptor blockers (ARBs): proven antiproteinuric and renoprotective; ARBs are first choice if ACE inhibitors are not tolerated (4)[A].
Combination ACE inhibitor and ARB should not be used. Although shown to reduce proteinuria, combination does not reduce poor CV outcomes and does increase risk of adverse drug reactions (5,6)[A].

β-Blockers: antiproteinuric and cardioprotective (4)[A]
Dihydropyridine calcium channel blockers (DHCCBs): should be avoided unless needed for BP control; not antiproteinuric (4)[A]
Non-DHCCB: antiproteinuric, may be renoprotective (4)[B]
Aldosterone antagonists: antiproteinuric independent of BP control (4)[B]
NSAIDs: antiproteinuric but also nephrotoxic; generally should be avoided (4)[C]

ISSUES FOR REFERRAL
Consider nephrology referral for possible renal biopsy if
- Impaired creatinine clearance
- Nephrotic-range proteinuria
- Unclear etiology of nonnephrotic-range proteinuria
- Diabetics with microalbuminuria

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Corticosteroids: No proven benefit in mortality or need for renal replacement in adults with nephrotic syndrome, although steroids are recommended in some patients who do not respond to conservative treatment. Classically, children with nephrotic syndrome respond better than adults, especially those with minimal-change disease (6)[A].
- Estrogen/progesterone replacement: may be renoprotective in premenopausal women but should be avoided in postmenopausal women (4)[B]
- Antioxidant therapy: may be antiproteinuric in diabetic nephropathy (4)[C]
- Sodium bicarbonate: not antiproteinuric but may block tubular injury caused by proteinuria; correcting metabolic acidosis may decrease protein catabolism (4)[C].
- Avoid excessive caffeine consumption: antiproteinuric in diabetic rat models (4)[C]
- Avoid iron overload (4)[C].
- Pentoxifylline: prevents progression of renal disease by unclear mechanisms (4)[C]
- Mycophenolate mofetil: antiproteinuric and renoprotective in animal models (4)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
All patients with persistent proteinuria should be followed with serial BP checks, UA, and renal function tests in the outpatient setting. Intervals depend on underlying etiology.

PROGNOSIS
● Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.
● Clinical significance of persistent proteinuria varies greatly and depends on underlying etiology.
● Degree of proteinuria is associated with disease progression in chronic kidney disease.
● Independent of GFR, higher levels of proteinuria likely convey an increased risk of mortality, myocardial infarction, and progression to kidney failure.

**COMPlications**
● Progression to chronic renal failure and the need for dialysis/renal transplant
● Hypercholesterolemia
● Hypercoagulable state
● Increased risk for infection for patient with nephrotic syndrome
● In nephrotic syndrome, ACIP recommends first dose of PCV13, followed by first dose of PPSV23 ≥8 weeks and then second dose of PPSV23 5 years after the first PPSV.

**REFERENCES**

**CODEs**

**ICD10**

- R80.9 Proteinuria, unspecified
- R80.2 Orthostatic proteinuria, unspecified
- R80.1 Persistent proteinuria, unspecified

**CLINICAL PEARLS**

- Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.
● Proteinuria >2 g/day likely represents glomerular malfunction and warrants a nephrology consultation.
● Clinical course varies greatly but, in general, the degree of proteinuria correlates with kidney disease progression.
● First-line therapy for persistent proteinuric patients is a high-dose ACE inhibitor.
PROTHROMBIN 20210 (MUTATION)
Katyayini Aribindi, MD ● Adrian DaSilva-DeAbreu, MD ● Raymundo A. Quintana, MD

BASICS

DESCRIPTION

- The G20210A is a gain of function mutation where adenine is substituted for a guanine at the 20210 noncoding position of the prothrombin (a.k.a. factor II) gene.
- Prothrombin 20210 mutation is the second most common venous thrombophilia after the factor V Leiden mutation.
- The mechanism of increasing the risk of thrombosis is incompletely understood but has been attributed to increased prothrombin or factor II levels in circulation by increased prothrombin protein translation without changing the levels of prothrombin mRNA transcription.
- Autosomal dominant condition, where heterozygotes have a 30% higher prothrombin level and a 3- to 4-fold increased risk of venous thromboembolism (VTE).
- System(s) affected: cardiovascular, hematologic/lymphatic/immunologic, nervous, pulmonary, reproductive, and hepatic
- Synonym(s): prothrombin G20210A mutation; prothrombin G20210A gene polymorphism; prothrombin gene mutation; and FII A20210 mutation

EPIDEMIOLOGY

- Found largely in Caucasian population with a prevalence ranging between 1% and 6%, but overall, it is about 2%.
- In patients presenting with a VTE, prothrombin 20210 mutation has a prevalence that ranges from 4.6% to 18% with increased prevalence attributed to highly thrombophilic families.
- Mean age of first thrombosis is in the 2nd decade of life.
- Inheritance is similar between both genders (autosomal).

ETIOLOGY AND PATHOPHYSIOLOGY

- Noncoding substitution of adenine for guanine at the 20210 position at the terminal nucleotide of the 3′ resulting in a gain of function of prothrombin gene, leading to increased levels of prothrombin (factor II), by increased translation of prothrombin mRNA but not transcription.
- The base change location is in the 3′ terminal nucleotide of the untranslated region associated with the mRNA sequence for polyadenylation. The gain of function is possible due to increased rate of processing, alteration of the site of cleavage, or increased mRNA stability.
- In the coagulation cascade, prothrombin (factor II) is the precursor of thrombin, which cleaves fibrinogen to fibrin. Elevated prothrombin activity leads to elevated thrombin levels and subsequent clot formation.
- The majority of thrombus formation occurs in the venous circulation: deep venous thrombosis (DVT)/PE, mesenteric, and cerebral. Recent studies have shown that prothrombin 20210 mutation did not correlate with Budd-Chiari syndrome or a portal or hepatic vein thrombosis.
- G20210A mutation is not known to be a risk factor for some arterial thrombotic events (myocardial infarction or acute ischemic stroke); however, studies have shown an increased prevalence of the mutation in patients with critical limb ischemia (1).
Genetics
- Caused by the G20210A mutation of the F2 gene (prothrombin gene) located in the short (p) arm of chromosome 11 that causes a gain of function
- Heterozygotes have a 30% increased levels of prothrombin levels, with a 3- to 4-fold increase of VTE events. Homozygotes are at an even greater risk.
- There are three other prothrombin mutations not related to the G20210A area:
  - Yukuhashi: missense mutation G1787T, arginine for leucine at amino acid 596, leading to prolonged procoagulant activity
  - C20209T: adjacent to G20210A mutation, primarily found in African individuals; newer studies have suggested a possible relationship between this mutation and recurrent pregnancy loss, although it is not fully understood.
  - A19911G: located in the intron of the prothrombin gene; may affect the G20210A mutation by increasing the odds ratio of the venous thromboembolic event. Mechanism is still unknown.

RISK FACTORS
- Being a hereditary condition, the presence of such mutation in the parents poses risk of transmission to offspring.
- Regarding the risk of developing VTE:
  - Patients with both the prothrombin 20210 mutation and factor V Leiden mutation increases the odds ratio of VTE by 20-fold.
  - Virchow triad of thrombogenesis consists of stasis, endothelial injury, and thrombophilia. Any condition that promotes stasis and endothelial injury will consequently increase the risk of VTE, for example, oral contraceptive, pregnancy, malignancy, orthopedic surgery, congestive heart failure, cerebrovascular accident in the past 3 months, air travel, obesity, and smoking.

Pregnancy Considerations
- Increased thrombotic risk in patients with prothrombin 20210 mutation during pregnancy and in the postpartum state is attributed to relative stasis.
- Anticoagulation should begin in the 1st trimester because the risk of VTE increases early in pregnancy and should be discontinued at onset of labor or before scheduled induction/cesarean delivery. Postpartum risk of VTE is usually greater, and anticoagulation can resume 4 to 6 hours after a vaginal delivery or 6 to 12 hours after surgery. Warfarin may begin immediately due to slow onset of action.
- C20209T mutation may have some relation with recurrent pregnancy loss; however, it is not well studied (2).

GENERAL PREVENTION
Asymptomatic individuals with the mutation do not require any prophylactic anticoagulation. Exceptions are generally made for pregnant women with very high-risk thrombophilic mutations (usually factor V Leiden) with a strong family history. After the first VTE, lifelong prophylaxis may be warranted if some features are present: unprovoked or in a nontraditional area like hepatic, portal, mesenteric, or cerebral.

COMMONLY ASSOCIATED CONDITIONS
- VTE
- Factor V Leiden
DIAGNOSIS

HISTORY
- Previous VTE
- Family history of VTE
- Family history of prothrombin 20210 mutation

PHYSICAL EXAM
- Unilateral swollen, erythematous, and tender calf is significant for a possible DVT.
- Positive Homans sign, sensitivity of 10–54%, specificity of 39–89% for DVT
- Tachycardia is the most common sign of a pulmonary embolism; however, patients may have chest pain and hypotension depending on the severity of the pulmonary embolus.
- A tender abdomen may be indicative of mesenteric veins thrombosis; however, other causes of an acute abdomen should be worked up as appropriate.

DIFFERENTIAL DIAGNOSIS
- Factor V Leiden mutation
- Protein C deficiency
- Protein S deficiency
- Antithrombin deficiency
- Other causes of activated protein C resistance (e.g., antiphospholipid antibodies)
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Elevated factor VIII levels

DIAGNOSTIC TESTS & INTERPRETATION
Screening for prothrombin G20210A mutation in asymptomatic individuals is not recommended; except for those with very strong family history (3)[B]. Testing can take place in patients with thrombosis at a very early age, recurrent unprovoked VTE, or those with thrombosis in unusual locations.

Initial Tests (lab, imaging)
- This mutation can be diagnosed using PCR with electrophoresis or immunoassays.
- Imaging should be obtained as appropriate for the suspected site of thrombosis: ultrasound with Doppler, computed tomography scan with contrast to evaluate venous phase, and V/Q scan.
- Testing for an inherited thrombophilic condition is reliable during an acute embolic event or with anticoagulation use (4)[A].

Follow-Up Tests & Special Considerations
Although prothrombin levels are elevated, this is not a sensitive test to make the diagnosis.

Diagnostic Procedures/Other
MR angiography (MRA), venography, or arteriography to detect thrombosis

Test Interpretation
Imaging is likely to show presence of arterial or venous thrombus.
TREATMENT

GENERAL MEASURES
Management of patients with a first-time VTE with or without an acquired thrombophilic condition remains overall very similar.

MEDICATION
Is directed to treat those patients with VTE (prophylactic doses may vary). We recommend the reader to check the most updated doses, dose adjustments, and contraindications for the medications listed below. The doses listed apply to most adults.

First Line
In adult patients without cancer, the following oral anticoagulants are preferred over warfarin and low-molecular-weight heparin (LMWH): dabigatran, rivaroxaban, apixaban, or edoxaban are preferred over warfarin (5)[A].

- Apixaban (Eliquis): Initial dose is 10 mg BID for 7 days, followed by 5 mg BID.
- Dabigatran (Pradaxa): requires initial parenteral anticoagulation for 5 to 10 days, followed by 150 mg BID
- Edoxaban (Savaysa): requires initial parenteral anticoagulation for 5 to 10 days, followed by 60 mg daily
- Rivaroxaban (Xarelto): Initial dose is 15 mg BID with food for 21 days, followed by a daily dose of 20 mg with food.

Second Line
For patients without cancer that cannot be treated with DOAC, warfarin is preferred over LMWH (5)[A].

- Warfarin (Coumadin): Initial dose may range from 2 to 10 mg PO daily and then adjusted to an INR of 2 to 3.
- Enoxaparin (Lovenox): 1 mg/kg subcutaneous injection every 12 hours

MEDICATION CONSIDERATIONS
- Contraindications
  - Absolute contraindications: active bleeding, severe bleeding diathesis, planned or recent high bleeding risk surgery or procedure, major trauma, recent or history of intracranial hemorrhage
  - Relative contraindications: recurrent gastrointestinal bleeding, intracranial or spinal tumors, thrombocytopenia with platelets <50,000 (enoxaparin can be dose adjusted depending on severity of thrombocytopenia), large AAA with severe hypertension, recent or emergent low bleeding risk surgery
  - Warfarin: history of warfarin skin necrosis
  - Doses of LMWH and new oral anticoagulants need to be adjusted in patients with renal dysfunction. Rivaroxaban should be avoided in patients with severe renal dysfunction. Apixaban may be relatively safer to use in patients with CKD and has a significantly lower risk of major bleeding or clinically relevant nonmajor bleeding than rivaroxaban or dabigatran (6)[A].
  - Apixaban can be given for DVT prophylaxis as well as at a reduced dose of 2.5 mg PO BID.
- Precautions
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Periodically monitor CBCs.
  - Oral contraceptives are generally avoided in women already known to have the mutation; however, it is not recommended to check for the mutation before starting oral contraceptives in asymptomatic women.
- Complications of medications
  - Heparins: heparin-induced thrombocytopenia
  - Warfarin may cause necrotic skin lesions (typically breasts, thighs, or buttocks).
- Significant possible interactions
  - Agents that increase the effect of some anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that decrease the effect of some anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

**ISSUES FOR REFERRAL**
- Recurrent thrombosis on anticoagulation
- Difficulty anticoagulating
- Genetic counseling

**SURGERY/OTHER PROCEDURES**
- Anticoagulation must be held for surgical interventions.
  - For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation, except in case with contraindication to anticoagulation (5)[A].
  - Thrombectomy may be necessary in some cases.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization: complicated thrombosis, such as pulmonary embolus; required heparin drip
  - Patient can be safely discharged if patient is stable on anticoagulation.

**ONGOING CARE**
- Compression stockings for prevention
- DVT prophylaxis as appropriate if patient admitted to hospital

**FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**
- Warfarin use requires periodic (weekly and then monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (5)[A].
- Heterozygosity for the prothrombin 20210 mutation increases the risk for recurrent VTE only slightly, thus its presence does not alter the length of anticoagulation treatment decision.

**DIET**
No restrictions; unless taking warfarin
Food rich in vitamin K may interfere with warfarin anticoagulation.
Grapefruit and St. John’s wort interfere with the cytochrome P450 and can alter the levels and clearance of anticoagulant therapy.

PATIENT EDUCATION
Patients should be educated about:
- Use of oral anticoagulant therapy
- Signs and symptoms of acute blood loss
- Avoidance of NSAIDs while on warfarin

PROGNOSIS
When compared with normal individuals, persons with prothrombin 20210 have normal lifespans.

COMPLICATIONS
- Recurrent thrombosis on anticoagulation
- Bleeding on anticoagulation
- Complications are usually location dependent and can lead to death, possibly from a massive pulmonary embolism.
- Venous stasis ulcers

REFERENCES

ADDITIONAL READING
Prothrombin 20210 mutation is the second most common inherited risk factor for VTE after factor V Leiden mutation. Asymptomatic patients with prothrombin 20210 mutation do not need anticoagulation or screening. Management of VTE is no different with or without the prothrombin G20210A mutation. However, indefinite anticoagulation may be considered in people with an unprovoked VTE or thrombus in a nontraditional area (mesenteric or cerebral).
PRURITUS ANI
Marie L. Borum, MD, EdD, MPH, MACP, FACG, AGAF • Scott Baumgartner, MPAS

**BASICS**

**DESCRIPTION**
- Intense anal/perianal itching and/or burning
- Usually acute
- Classified as primary (idiopathic) or secondary (25–75% of cases) to anorectal pathology

**EPIDEMIOLOGY**

**Incidence**
- 1–5% of the general population
- Predominant age: 30 to 50 years; although seen in all age groups
- Predominant sex: male > female (4:1)

**Prevalence**
Difficult to estimate because many patients do not report symptoms. Affects 1–5% of the population

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Multiple etiologies categorized by inflammatory, infectious, systemic, neoplastic, neuropathic, neurogenic, and psychogenic causes
- Most cases are idiopathic (25–90%)
- Pruritus may create an irresistible desire to scratch leading to a self-perpetuating “itch–scratch–itch” cycle.
- Pruritus ani is typically intensely perceived by the patient due to dense innervation.
- Consider primary pruritus ani when no other demonstrable causes can be found, including:
  - Poor anal hygiene
  - Loose or leaking stool that makes hygiene difficult. Patients with abdominal ostomy bags typically do not complain of pruritus.
  - Internal sphincter laxity
- Etiologies of secondary pruritus ani:
  - Inflammatory dermatologic diseases:
    - Allergic contact dermatitis (soaps, perfumes, or dyes in toilet paper, topical anesthetics, oral antibiotics)
    - Atopic dermatitis ± lichen simplex chronicus (patients also have asthma and/or eczema)
    - Psoriasis (lesions tend to be poorly demarcated, pale, and nonscaling)
    - Seborrheic dermatitis
    - Scleroderma
    - Lichen planus (may be seen in patients with ulcerative colitis and myasthenia gravis)
    - Radiation dermatitis
  - Colorectal/anorectal diseases: rectal prolapse, hemorrhoids, fissures or fistulas, chronic diarrhea/constipation, polyps
– Infectious etiologies, may be sexually transmitted: bacteria (gonorrhea, chlamydia, syphilis), viruses (herpes simplex virus [HSV], condyloma acuminata from human papillomavirus [HPV], molluscum), parasites (pinworms, lice, scabies, or bed bugs), fungal (Candida, or dermatophytes like tinea); other bacteria (Staphylococcus aureus, β-hemolytic Streptococcus, Corynebacterium minutissimum [erythrasma]) (3)
– Malignancies: melanoma, basal cell/squamous cell carcinoma, colorectal cancer, leukemia, lymphoma, or (uncommon) the presenting symptom of Bowen or Paget disease
– Mechanical factors: vigorous cleaning and scrubbing, tight-fitting clothes, synthetic undergarments
– Systemic diseases (often presents as generalized pruritus): diabetes mellitus (most common), cholestasis, chronic liver disease, renal failure, hyperthyroidism, anemia
– Chemical irritants: chemotherapy, diarrhea (often from antibiotic use)
– Dietary elements (citrus, milk products, coffee, tea, cola, chocolate, beer, wine, tomatoes, nuts)
– Psychogenic factors: anxiety–itch–anxiety cycle

RISK FACTORS
● Obesity
● Excess perianal hair growth and/or perspiration
● Underlying anorectal pathology
● Underlying anxiety disorder
● Caffeine intake has been correlated with symptoms.

GENERAL PREVENTION
● Good perianal hygiene; avoid overzealous hygiene
● Avoid mechanical irritation of skin (vigorous cleaning or rubbing with dry toilet paper or baby wipes, harsh soaps or perfumed products, excessive scratching with fingernails, or tight/synthetic undergarments).
● Minimize moisture in perianal area (absorbent cotton in anal cleft may help keep area dry).
● Avoid laxative use (loose stool is an irritant).

DIAGNOSIS
HISTORY
● Patients present with complaints of anal and/or perianal itching, burning, or excoriation.
● Inquire about:
  – Timing (when it started, when it is worse)
  – Perianal hygiene (frequency of cleansing and products used)
  – Change in bowel habits
  – Bleeding (spotting of toilet paper, melena, hematochezia)
  – Recent antibiotic use
  – Skin disorders (psoriasis, eczema)
  – Rectal or vaginal discharge, menstrual cycle
  – Dietary history: Focus on the “C”s: caffeine, coffee, cola, chocolate, citrus, calcium (dairy) (3).
  – Medical history (hepatitis, iron deficiency anemia, and diabetes in particular)
- Family history of colorectal cancer
- Anal receptive intercourse
- Change in toiletry products
- Household members (particularly children) with itching (possible pinworms)
- Clothing preference (tight, synthetic) (1)

**PHYSICAL EXAM**
- Perianal visual inspection for erythema, hemorrhoids, anal fissures, maceration, lichenification, warts, polyps, excoriations, neoplasia, stool seepage
- Classification based on gross appearance
  - Stage 1: erythema, inflamed appearance
  - Stage 2: lichenification
  - Stage 3: lichenification, coarse skin, potential fissures or ulcerations (1)
- Digital rectal exam to evaluate for masses, internal sphincter tone, pain
- Valsalva to evaluate for prolapse
- Anoscopy to evaluate for hemorrhoids, fissures, other internal lesions

**DIFFERENTIAL DIAGNOSIS**
- “ITChE” acronym (4)
  - Infection: Candida, parasites (scabies, pinworms), HPV, HSV, bacterial (gram-positive bacteria, gonorrhea, chlamydia, syphilis)
  - Topical irritants: soaps/detergents, garments, deodorants, perfumes, stool leakage
  - Cutaneous/Cancer/Colorectal: eczema, psoriasis, lichen planus, lichen sclerosus, seborrhea, skin cancer, extramammary Paget disease, Bowen disease, fistula, fissure, prolapase, hemorrhoids, colorectal cancer
  - Hypersensitivity: foods, medications (colchicine, quinidine, mineral oil)
  - eSSystemic: diabetes, iron deficiency anemia, uremia, cholestasis, hematologic malignancy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Use history and exam to suggest a specific etiology, and guide testing:
- Pinworm tape test; stool for ova and parasites
- CBC, comprehensive metabolic panel, A1c, thyroid studies to identify underlying systemic disease
- Wood lamp examination will show coral-red fluorescence in erythrasma (3).
- Skin scraping with potassium hydroxide (KOH) prep for dermatophytes or candidiasis (as etiology or as superinfection) and mineral oil prep for scabies
- Perianal skin culture (bacterial superinfection)
- Hemoccult testing of stool

**Pediatric Considerations**
Pinworms common in children. Consider perianal Crohn disease (5).

**Follow-Up Tests & Special Considerations**
Anal DNA polymerase chain reaction (PCR) probe for gonorrhea and chlamydia. Test for anal HPV if receptive anal intercourse.

**Diagnostic Procedures/Other**
Biopsy suspicious lesions (e.g., lichenification, ulcerated epithelium, refractory cases) to exclude neoplasia; evaluate etiology.

Consider colonoscopy if history, exam, or testing suggests colorectal pathology (family history of colorectal disease, especially if age >40 years, weight loss, rectal bleeding, change in bowel habits).

Geriatric Considerations
- Stool incontinence may be a predisposing factor.
- Consider systemic disease.
- Higher likelihood of colorectal pathology

TREATMENT

GENERAL MEASURES
- Proper anal/perianal hygiene. Avoid chemical and mechanical irritants and wear proper undergarments (1).
- High-fiber diet and/or bowel regimen to maintain regular bowel movements (1)
- Avoid tight-fitting clothing. Use cotton undergarments.
- Avoiding moisture; absorbent cotton, talcum powder, or cornstarch if excess moisture (1)
- Cotton gloves at night to control nocturnal scratching

MEDICATION

First Line
- Treat underlying infections: fungal or dermatophyte infection with topical imidazoles, bacterial infection with topical antibacterials.
- Treat underlying anorectal anatomic pathology: banding of prolapsing internal hemorrhoids, fistulas, or fissures.
- Break itch–scratch cycle with low-potency steroid cream such as hydrocortisone 1% ointment applied sparingly up to 4 times daily (1). Discontinue when itching subsides. Avoid use >2 weeks due to risk of skin atrophy.
- If no response with low-potency steroid, consider high-potency steroid cream.
- Antihistamines, particularly sedating antihistamines, may be useful in reducing nighttime itching until local measures take effect (4).
- Tricyclic antidepressants may reduce nighttime scratching.
- Zinc oxide can be used after steroid course for barrier protection (3); petroleum jelly is another barrier (mineral oil can worsen pruritus).
- Low-dose topical capsaicin cream in combination with steroid cream if refractory symptoms (1)
- 0.03% tacrolimus ointment as an option to avoid atrophy associated with prolonged steroid use (1)
- Several small case series have shown symptomatic benefit with intradermal methylene blue injection—this may be an additional option for patients with refractory pruritus.
- Albendazole for pinworm.

Second Line
Radiation may be used to destroy nerve endings (create permanent anesthesia) in intractable
cases. This is almost never indicated but is very effective.

**ISSUES FOR REFERRAL**

- Intractable pruritus: Consider referral to gastroenterology (for colonoscopy) or dermatology (for additional treatment, possibly injections, or biopsies). Refractory or persistent symptoms should signal the possibility of underlying neoplasia because pruritus ani of long duration is associated with a greater likelihood of colorectal pathology.

- Refer for colonoscopy if at risk for colon cancer.

**SURGERY/OTHER PROCEDURES**

As above, especially if concern for malignancy identified

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

See patient every 2 weeks if not improving. Ensure proper hygiene and avoidance of irritants. Work up for systemic disease, and check for persistent lichenification. If refractory pruritus or lichenification does not resolve, consider underlying malignancy.

**DIET**

- Eliminate foods and beverages known or suspected to exacerbate symptoms: coffee, tea, chocolate, beer, cola, vitamin C tablets in excessive doses, citrus fruits, tomatoes, or spices.

- Eliminate foods or drugs contributing to loose bowel movements or dermatitis.

- Add fiber supplementation to bulk stools and prevent fecal leakage in patients who have fecal incontinence or partially formed stools.

**PATIENT EDUCATION**

- Review proper anal hygiene:
  - Resist overuse of soap and rubbing.
  - Avoid products with irritating perfumes and dyes.
  - Avoid use of ointments and mineral oil.
  - Wear loose, light cotton clothing.
  - If moisture is a problem, use cotton, unmedicated talcum powder, or cornstarch to keep the area dry.
  - Cleanse perianal area after bowel movements with water-moistened cotton.
  - Dry area after bathing by patting with a soft towel or by using a hair dryer on cool setting (1).

- Avoid medications that cause diarrhea or constipation.

- Avoid caffeine, cola, chocolate, citrus, tomatoes, tea, alcohol, nuts, and milk products (3)[C].

- Use barrier protection if engaging in anal intercourse.

- If unable to completely empty rectum with defecation, use small plain-water enema (infant bulb syringe) after each bowel movement to prevent soiling and irritation.

- If persists, consider underlying medical disease.

**PROGNOSIS**

- Conservative treatment successful in ~90% of cases

- Idiopathic pruritus ani is often chronic—waxes and wanes.
COMPLICATIONS
- Bacterial superinfection at site of excoriations and potential abscess formation or penetrating infection via self-inoculation with colonic pathogens
- Lichenification
- Significant effect on quality of life

Pinworms; Pruritus Vulvae

CODES
ICD10
L29.0 Pruritus ani

CLINICAL PEARLS
- Pruritus ani is characterized by anal/perianal itching and/or burning. It is a skin irritation with itch–scratch–itch cycle.
- Conservative treatment with perianal hygiene and reassurance is successful in 90% of patients.
- Consider trial of dietary elimination of “C”s—citrus, vitamin C supplements, calcium products, caffeine, coffee, cola, chocolate.
- Rule out infection (viral, bacterial, parasitic) in immunosuppressed patients.
- Consider underlying malignancy if refractory.
PRURITUS VULVAE
Maeve K. Hopkins, MD ● Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION
- Pruritus vulvae is a symptom or can be a primary diagnosis.
- If a primary diagnosis other etiologies must be excluded.
- Pruritus vulvae as a primary diagnosis may also be more appropriately documented as vulvodynia (see “Vulvodynia” topic) or burning vulva syndrome.

EPIDEMIOLOGY
Symptoms may occur at any age during a woman’s lifetime.
- Young girls most commonly have infectious or hygiene etiology.
- The primary diagnosis is more common in postmenopausal women.

Incidence
The exact incidence is unknown, although most women complain of vulvar pruritus at some point in their lifetime.

ETIOLOGY AND PATHOPHYSIOLOGY
Vulvar tissue is more permeable than exposed skin due to differences in structure, occlusion, hydration, and susceptibility to friction. It is particularly vulnerable to irritants such as:
- Perfumes
- Soaps
- Vaginal hygiene products
- Topical medications
- Dyes
- Body fluids

RISK FACTORS
- High-risk sexual behavior
- Immunosuppression
- Obesity

GENERAL PREVENTION
- Avoid irritants.
- Tight-fitting clothing should be avoided.
- Only cotton underwear should be worn.

COMMONLY ASSOCIATED CONDITIONS
- Infectious etiology
  - Vaginal or vulvar candida
  - Gardnerella vaginalis
  - Trichomonas
  - Human papillomavirus
  - Herpes simplex virus
Vulvar vestibulitis
Lichen sclerosus
Lichen planus
Lichen simplex chronicus (squamous cell hyperplasia)
Malignant or premalignant conditions
Psoriasis
Fecal or urinary incontinence
Dermatophytosis
Parasites: scabies, Pthirus pubis
Extramammary Paget
Dietary: methylxanthines (e.g., coffee, cola), tomatoes, peanuts
Autoimmune progesterone dermatitis: perimenstrual eruptions
Irritant or allergic contact dermatitis
Atopic dermatitis

DIAGNOSIS

Pruritus vulvae is a diagnosis of exclusion. Delay in diagnosis is common due to patient hesitancy to seek treatment or provider delay in biopsy. Delayed diagnosis can have profound negative effect on women’s sexual comfort and quality of life (2).

HISTORY

- Persistent itching
- Persistent burning sensation over the vulva or perineum
- Change in vaginal discharge
- Postcoital bleeding
- Dyspareunia

PHYSICAL EXAM

- Visual inspection of the vulva, vagina, perineum, and anus
  - Superior surfaces of the labia majora—extending from mons to the anal orifice—are most involved.
  - Vulvar skin is leathery or lichenified in appearance.
  - Papillomatosis may be a sign of chronic inflammation.
- Cotton swab–applied pressure to area of pain and to vestibular glands
- Musculoskeletal evaluation to confirm not contributing if persistent vulvar pain

DIAGNOSTIC TESTS & INTERPRETATION

- Sodium chloride: Gardnerella or Trichomonas
- 10% potassium hydroxide: Candida
- Viral culture or polymerase chain reaction: herpes simplex virus
- Directed biopsy recommended (3)[B]: human papillomavirus, lichen, malignancy, chronic inflammation
- Colposcopy with acetic acid or Lugol solution of vagina and vulva

Follow-Up Tests & Special Considerations

- A patch test may be performed by a dermatologist to assist in identifying a causative agent if
contact dermatitis is suspected or if topical products are suspected as source of dermatitis (4) [A].

- Exam-directed tissue biopsies are essential in the postmenopausal population to rule out malignancy.

**Diagnostic Procedures/Other**

Biopsies should be collected from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus.

**Test Interpretation**

- Only in the absence of pathologic findings can the primary diagnosis of pruritus vulvae be made.
- Biopsies of visible lesions most commonly show lichen simplex chronicus (25%), lichen sclerosus (20%), or chronic inflammation (15%) (3).

---

**TREATMENT**

Identify the underlying cause or disease to target treatment.

- Stop all potential irritants.
- Eliminate bacterial and fungal infection.
- Cool the affected area: Use cool gel packs (not ice packs, which may cause further injury).
- Sitz baths and bland emollients to soothe fissured or eroded skin

**MEDICATION**

**First Line**

- Topical steroids (1,5)
  - Triamcinolone 0.1% applied daily for 2 to 4 weeks and then twice weekly
  - Hydrocortisone 1–2.5% cream applied 2 to 4 times daily
  - Avoid long-term use due to risk of atrophy.
- 1st-generation antihistamines
  - Hydroxyzine: Initiate with 10 mg before bedtime (slowly increase up to 100 mg).
  - Doxepin: Initiate with 10 mg before bedtime.
  - 2nd-generation antihistamines are of little benefit.

**Second Line**

- SSRI such as citalopram 20 to 40 mg for resistant cases (6)
- Calcineurin inhibitors such as 1% pimecrolimus (5)[A]

**ISSUES FOR REFERRAL**

- Persistent symptoms should prompt additional investigation and referral to a gynecologist or gynecologic oncologist.
- Gynecologic oncology referral for proven or suspected malignancy
- Dermatology referral for patch testing to evaluate for contact dermatitis

**ADDITIONAL THERAPIES**

- Sacral neuromodulation device
- Laser therapy
- GnRH analogues
Naltrexone

ONGOING CARE
- Frequent evaluation, repeat cultures, and biopsies are necessary for cases resistant to treatment.
- Refractory cases may require referral to gynecologist or gynecologic oncology for further management.

DIET
Dietary alterations include avoidance of the following:
- Coffee and other caffeine-containing beverages
- Tomatoes
- Peanuts

PATIENT EDUCATION
- American College of Obstetricians and Gynecologists: https://www.acog.org
- National Vulvodynia Association: https://www.nva.org

PROGNOSIS
Conservative measures and short-term topical steroids control most patients’ symptoms.

COMPLICATIONS
Malignancy

REFERENCES

ADDITIONAL READING
- Hill A, Paraiso M. Resolution of chronic vulvar pruritus with replacement of a

**CODES**

**ICD10**

- L29.2 Pruritus vulvae
- N94.819 Vulvodynia, unspecified

**CLINICAL PEARLS**

- Pruritus vulvae is a common complaint.
- Pruritus vulvae is a diagnosis of exclusion once other causes of itching have been ruled out.
- Exam-directed biopsies from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus are essential to rule out malignancy.
- Initial treatment is conservative.
PSEUDOFOLLICULITIS BARBAE
Maurice Duggins, MD

BASICS

DESCRIPTION
- Foreign body inflammatory reaction from an ingrown hair resulting in the appearance of papules and pustules. This is found mainly in the bearded area (barbae) but may occur in other hairy locations such as the scalp, axilla, or pubic areas where shaving is done (1).
- A mechanical problem: extrafollicular and transfollicular hair penetration
- System(s) affected: skin/exocrine
- Synonym(s): chronic sycosis barbae; pili incarnati; folliculitis barbae traumatica; razor bumps; shaving bumps; tinea barbae; pseudofolliculitis barbae (PFB)

EPIDEMIOLOGY
- Predominant age: postpubertal, middle age (14 to 25 years) (2)
- Predominant sex: male > female (can be seen in females of all races who wax/shave)

Incidence
- Adult male African Americans: unknown
- Adult male whites: unknown

Prevalence
- Widespread in Fitzpatrick skin types IV to VI (darker complexions) who shave
- 45–83% of African American soldiers who shave (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Transfollicular escape of the low-cut hair shaft as it tries to exit the skin is accompanied by inflammation and often an intraepidermal abscess.
- As the hair enters the dermis, more severe inflammation occurs, with downgrowth of the epidermis in an attempt to sheath the hair.
- A foreign body reaction forms at the tip of the invading hair, followed by abscess formation.
- Shaving too close
- Plucking/tweezing or wax depilation of hair may cause abnormal hair growth in injured follicles.

Genetics
- People with curly hair have an asymmetric accumulation of acidic keratin hHa8 on hair shaft.
- Single-nucleotide polymorphism (disruption Ala12Thr substitution) affects keratin of hair follicle.

RISK FACTORS
- Curly hair
- Shaving too close or shaving with multiple razor strokes
- Plucking/tweezing hairs
- South Mediterranean/American, Middle Eastern, Asian, or African descent (skin types IV to VI)
GENERAL PREVENTION

- Prior to shaving, rinse face with warm water to hydrate and soften hairs.
- Use adjustable hair clippers that leave very low hair length above skin.
- Shave with either a manual adjustable razor at coarsest setting (avoids close shaves), a single-edge blade razor (e.g., Bump Fighter), a foil-guarded razor (e.g., PFB razor), or electric triple “O-head” razor.
- Empty razor of hair frequently.
- Shave in the direction of hair growth. Do not overstretch skin when shaving.
- Use a generous amount of the correct shaving cream/gel (e.g., Ef-Kay shaving gel, Edge shaving gel, Aveeno therapeutic shave gel, Easy Shave medicated shaving cream).
- Daily shaving reduces papules/pruritus.
- Regular use of depilatories

COMMONLY ASSOCIATED CONDITIONS

- Keloidal folliculitis
- Pseudofolliculitis nuchae

DIAGNOSIS

HISTORY

Pain on shaving; pruritus of shaved areas, irritated “razor bumps”

PHYSICAL EXAM

- Tender, exudative, erythematous follicular papules or pustules in beard area (less commonly in scalp, axilla, and pubic areas); range from 2 to 4 mm
- Hyperpigmented “razor or shave bumps”
- Alopecia
- Lusterless, brittle hair

DIFFERENTIAL DIAGNOSIS

- Bacterial folliculitis
- Impetigo
- Acne vulgaris
- Tinea barbae
- Sarcoidal papules

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Clinical diagnosis
- Culture of pustules: usually sterile; may show coagulase-negative Staphylococcus epidermidis (normal skin flora)
- Additional hormonal testing may be indicated in females with hirsutism and/or polycystic ovary syndrome: dehydroepiandrosterone sulfate, luteinizing hormone (LH)/follicle-stimulating hormone (FSH), and free and total testosterone (3)[C].

Test Interpretation

Follicular papules and pustules
**TREATMENT**

- **Mild cases**
  - Stop shaving or avoid close shaving for 30 days while keeping beard groomed and clean \(^{(1,2)}[C]\).
  - Consider 5% benzoyl peroxide after shaving and application of 1% hydrocortisone cream at bedtime (or LactiCare-HC lotion after shaving) \(^{(2)}[C]\).
  - Tretinoin 0.025% cream; apply daily \(^{(1)}[C]\).

- **Moderate cases**
  - Chemical depilatories (barium sulfide; Magic shaving powder); first test on forearm for 48 hours (for irritation) \(^{(1,2,3)}[B]\).
  - Consider eflornithine HCl cream (Vaniqa) to reduce hair growth and stiffness in combination with other therapies \(^{(1,4)}[B]\).

- **Severe cases**
  - Laser therapy: Longer wavelength laser (e.g., neodymium [Nd]:YAG) is safer for dark skin \(^{(5)}[B]\).
  - Avoid shaving altogether; grow beard \(^{(1,2,3)}[C]\).

**GENERAL MEASURES**

**Acute treatment**
- Dislodge embedded hair with sterile needle/tweezers.
- Discontinue shaving until red papules have resolved (minimum 3 to 4 weeks; longer if moderate or severe); can trim to length >0.5 cm during this time
- Massage beard area with washcloth, coarse sponge, or a soft brush several times daily.
- Hydrocortisone 1–2.5% cream to relieve inflammation
- Selenium sulfide if seborrhea is present and to help reduce pruritus
- Systemic antibiotics if secondary infection is present

**Pregnancy Considerations**
Do not use tretinoin (Retin-A), tetracycline, or benzoyl peroxide.

**MEDICATION**

**First Line**
- Topical or systemic antibiotic for secondary infection
  - Application of clindamycin (Cleocin T) solution BID or topical erythromycin
  - Low-dose erythromycin or tetracycline 250 to 500 mg PO BID for more severe inflammation
  - Benzoyl peroxide 5%–clindamycin 1% gel BID: Administer until papule/pustule resolves.
- Mild cases: tretinoin 0.025% cream at bedtime; combination of the above therapies
- Moderate disease/chemical depilatories
  - Disrupt cross-linking of disulfide bonds of hair to produce blunt (less sharp) hair tip.
  - Apply no more frequently than every 3rd day: 2% barium sulfide (Magic Shave) or calcium thioglycolate (Surgex); calcium hydroxide (Nair)
- Contraindications
  - Clindamycin: hypersensitivity history; history of regional enteritis or ulcerative colitis; history of antibiotic-associated colitis
  - Erythromycin, tetracycline, tretinoin: hypersensitivity history
● **Precautions**
  – Clindamycin: colitis, eye burning and irritation, skin dryness; pregnancy Category B
  – Erythromycin: Use cautiously in patients with impaired hepatic function; GI side effects, especially abdominal cramping; pregnancy Category B (erythromycin base formulation)
  – Chemical depilatories: Use cautiously; frequent use and prolonged application may lead to irritant contact dermatitis and chemical burns.
  – Tetracycline: Avoid in pregnancy.
  – Tretinoin: severe skin irritation; avoid in pregnancy.
  – Benzoyl peroxide: skin irritation and dryness, allergic contact dermatitis
  – Hydrocortisone cream: local skin irritation, skin atrophy with prolonged use, lightening of skin color

● **Significant possible interactions**
  – Erythromycin: increases theophylline and carbamazepine levels; decreases clearance of warfarin
  – Tetracycline: depresses plasma prothrombin activity

**Second Line**
Chemical peels with either glycolic acid or salicylic acid

**ISSUES FOR REFERRAL**
● Worsening or poor response to the above therapies after 4 to 6 weeks should prompt dermatology consultation.
● Occupational demands may also prompt earlier referral to dermatology for more aggressive therapy.

**SURGERY/OTHER PROCEDURES**
Laser treatment with long-pulsed Nd:YAG is helpful for severe cases.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
● As needed
● Educate patient on curative and preventive treatment.

**DIET**
● No restrictions
● No dietary studies available

**PATIENT EDUCATION**
[https://medlineplus.com](https://medlineplus.com)

**PROGNOSIS**
● Good, with preventive methods
● Prognosis is poor in the presence of progressive scarring and foreign body granuloma formation.
COMPLICATIONS

- Scarring (occasionally keloidal)
- Foreign body granuloma formation
- Disfiguring postinflammatory hyperpigmentation (use sunscreens; can treat with hydroquinone 4% cream, Retin-A, clinical peels)
- Impetiginization of inflamed skin
- Epidermal (erythema, crusting, burns with scarring) and pigmentary changes with laser

REFERENCES

ADDITIONAL READING

SEE ALSO

Folliculitis; Impetigo

CODES

ICD10

- L73.1 Pseudofolliculitis barbae
B35.0 Tinea barbae and tinea capitis
L73.8 Other specified follicular disorders

CLINICAL PEARLS

- Electrolysis is not recommended as a treatment. It is expensive, painful, and often unsuccessful.
- Combination of laser therapy with eflornithine is more effective than laser alone.
- The unpleasant smell of sulfur could be a problem with some depilatory products.
- Have patient test for skin sensitivity with a small (coin sized) amount of the depilatory on the bearded area or forearm.
PSEUDOGOUT (CALCIUM PYROPHOSPHATE DIHYDRATE)
Juliana Chang, MD

BASICS

DESCRIPTION
- Autoinflammatory disease triggered by calcium pyrophosphate dihydrate (CPPD) crystal deposition within joints
- One of many diseases associated with pathologic deposition of crystal; mineralization and ossification
  - CPPD crystal deposition = chondrocalcinosis (calcification of hyaline or fibrocartilage), pseudogout, and pyrophosphate arthropathy
  - Monosodium urate crystal deposition = gout
  - Hydroxyapatite deposition associated with ankylosing spondylitis, osteoarthritis, and vascular calcification
- Suspect pseudogout with arthritis and a pattern of joint involvement inconsistent with degenerative joint disease (e.g., metacarpophalangeal joints, wrists).
- Clinical presentation is broad:
  - Asymptomatic CPPD (incidentally identified on radiograph with or without additional findings of osteoarthritis)
  - Acute CPPD arthritis (acute onset, self-limiting, synovitis)
    - Knee is affected in over 50% of all acute attacks vs. metatarsophalangeal in gout
    - Can be brought on by trauma, medical illness, or surgery (after parathyroidectomy) (1)
  - Chronic CPPD crystal inflammatory arthritis (2)[C]
- Chronic CPPD crystal deposition may cause a progressive degenerative arthritis in numerous joints; usually large joints; primarily in elderly patients
- Symptom onset is usually insidious.
- Definitive diagnosis requires the identification of CPPD crystals in synovial fluid.
- System(s) affected: endocrine/metabolic; musculoskeletal
- Synonyms: pseudogout; CPPD; pyrophosphate arthropathy; chondrocalcinosis

EPIDEMIOLOGY

Prevalence
- 80% of patients >60 years
- No gender predominance. Men more likely to present acutely; women more likely to present atypically
- Chondrocalcinosis present in 1:10 adults age 60 to 75 years, 1:3 age >80 years; only a small percentage develop arthropathy.
- 20–43% prevalence of CPPD crystals in synovial fluid of osteoarthritic joints at time of joint replacement

ETIOLOGY AND PATHOPHYSIOLOGY
- Arthropathy results from an acute autoinflammatory reaction to CPPD crystals in the synovial cavity.
CPPD crystal deposition occurs in three stages:
- Overproduction of anionic pyrophosphate (PPI) in articular cartilage
- PPI binds calcium to form CCPD crystals, eliciting an inflammatory response. Neutrophils engulf CPPD crystals, inducing extracellular trap formation.
- Increased CPPD crystal deposition causes inflammation and damage (3)[C].

Genetics
Rare familial pattern with autosomal dominant inheritance (<1% of patients); most cases are sporadic. Mutation in ANKH gene increases risk for calcium crystal formation.

RISK FACTORS
Advanced age; joint trauma

GENERAL PREVENTION
Colchicine 0.6 mg BID may be used prophylactically to reduce frequency of episodes in recurrent CPPD.

COMMONLY ASSOCIATED CONDITIONS
- Gout
- Hyperparathyroidism
- Amyloidosis
- Hemochromatosis; ochronosis
- Hypothyroidism
- Wilson disease
- Hypomagnesemia
- Familial hypocalciuric hypercalcemia
- X-linked hypophosphatemic rickets
- Acromegaly

DIAGNOSIS

HISTORY
- Presentation often mimics gout (“pseudogout”).
- Acute CPPD: pain and swelling of ≥1 or more joints; knee involved 50% of the time; ankle, wrist, toe, and shoulder are also common.
- Proximal joint involvement (mimicking polymyalgia rheumatica), often with tibiofemoral and ankle arthritis and tendinous calcifications
- Multiple symmetric joint involvement (mimicking rheumatoid arthritis) in <5% of cases
- May develop after intra-articular injection of hyaluronic acid (Hyalgan, Synvisc)
- Chronic CPPD: progressive degenerative arthritis with superimposed acute inflammatory attacks

PHYSICAL EXAM
- Inflammation (erythema, warmth, tender to touch), joint effusion, decreased range of motion (ROM)
- 50% associated with fever

DIFFERENTIAL DIAGNOSIS
Illnesses that may cause acute inflammatory arthritis in a single or multiple joint(s): gout, septic arthritis, trauma

Other acute inflammatory arthritides: Reiter syndrome, lyme disease, acute RA

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

Synovial fluid analysis shows an inflammatory effusion:

- Cell count 2,000 to 100,000 white blood cells (WBCs)/mL
- Neutrophil predominance (80–90%)
- >50,000 WBC count increases likelihood of septic arthritis; >100,000 WBCs/mL
- Polarized microscopy shows small number of positively birefringent crystals; high false-negative rate

Consider the following to exclude underlying disease:

- Serum calcium, phosphorus, and magnesium
- Serum alkaline phosphatase
- Serum parathormone (i-PTH)
- Serum iron, total iron-binding capacity, and serum ferritin
- Serum thyroid-stimulating hormone (TSH) level

Plain radiograph:

- Radiographic findings in pseudogout are neither sensitive nor specific.
- Punctate and linear calcifications in fibrocartilage, particularly of knees, hips, symphysis pubis, and wrists
- Chronic CPPD: subchondral cysts and loose bodies in joints not typically affected by degenerative joint disease

Ultrasound: joint effusion, synovial thickening, and hyperechoic deposits

- may be more useful than plain radiography for the diagnosis of pseudogout in peripheral joints, with a positive predictive value of 92% and negative predictive value of 93% (4)[C].

MRI: Chondrocalcinosis evident as hypointense lesions, particularly of knee menisci

**Diagnostic Procedures/Other**

**ALERT**

Synovial fluid analysis with demonstration of CPPD crystals is required for diagnosis; aspiration may help relieve symptoms and speed resolution.

**Test Interpretation**

CPPD crystal deposition in articular cartilage, synovium, ligaments, and tendons

**TREATMENT**

**GENERAL MEASURES**

Target symptom relief (reduce inflammation):

- Rest and elevate affected joint(s).
- Apply ice/cool compresses to affected joints.
- Non–weight-bearing on affected joint while painful; use crutches or a walker

**MEDICATION**
First Line
- Acute attacks: ice packs, rest, and joint aspiration with or without steroid injection
- Chronic CPPD: prophylactic management with oral NSAIDs and/or colchicine (4)[C]
- Oral NSAIDs
  - Ibuprofen 600 to 800 mg PO TID–QID with food; maximum 3.2 g/day
  - Naproxen 500 mg PO BID with food
  - Other NSAIDs are effective, although indomethacin has higher complication rates (relative risk [RR] = 2.2) compared with ibuprofen (RR = 1.2).
- Contraindications:
  - History of hypersensitivity to NSAIDs or aspirin
  - Active peptic ulcer disease or history of recurrent upper gastrointestinal (GI) lesions
  - Avoid in renal insufficiency.
  - Serious GI bleeding can occur without warning; patient should be instructed on signs/symptoms. Administer proton pump inhibitor (PPI) or misoprostol 200 μg PO QID in patients at risk for NSAID-induced gastric ulcers.
  - Caution in cardiovascular disease, particularly heart failure or difficult to control hypertension
  - Avoid in concomitant aspirin and anticoagulant use
- Oral colchicine: 0.5 mg up to 3–4 times daily, with or without 1 mg initial dose; 1.2 mg at the first sign of flare, followed in 1 hour
- Intra-articular steroid injection: Prednisolone sodium phosphate 4 to 20 mg or triamcinolone diacetate 2 to 40 mg with local anesthetic
- Supportive measures for symptomatic relief (application of ice or cool packs) and immobilization

Second Line
- Oral prednisone: 30 to 50 mg/day for 7 to 10 days
- IM triamcinolone acetonide 40 mg; if necessary, may repeat in 1 to 4 days
- Consider referring patients with large space-occupying tophaceous lesions for surgical removal.
- Alternative therapies for chronic CPPD
  - ACTH, anakinra (anti–IL-1), hydroxychloroquine, infliximab, probenecid, magnesium, ethylenediaminetetraacetic acid (EDTA) have all been suggested. Large scale studies are needed to evaluate effectiveness (5)[C].

ALERT
Recent randomized trial showed no significant effect of methotrexate in chronic-recurrent CPPD (6)[B].

ISSUES FOR REFERRAL
Consider consultation with orthopedist or rheumatologist if septic joint or patient is not responding.

ADDITIONAL THERAPIES
Physical therapy
- Isometric exercises to maintain muscle strength during the acute stage
- Begin joint ROM exercises as inflammation and pain subside.
- Resume weight bearing when pain subsides.
SURGERY/OTHER PROCEDURES
Perform arthrocentesis and joint fluid analysis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Consider admission for septic arthritis if:
- Synovial fluid WBC count >50,000/mL
- Treat with appropriate antibiotics pending culture results.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Reevaluate response to therapy 48 to 72 hours after beginning treatment; reexamine in 1 week, then as needed.

DIET
No known relationship to diet

PATIENT EDUCATION
- Rest affected joint.
- Symptoms usually resolve in 7 to 10 days.

PROGNOSIS
- Acute attack usually resolves in 10 days; prognosis for resolution of acute attack is excellent.
- Patients may experience progressive joint damage and functional limitation with recurrent attacks.

COMPLICATIONS
- Recurrent acute attacks
- Osteoarthritis

Geriatric Considerations
Elderly patients treated with NSAIDs require careful monitoring and are at higher risk for GI bleeding and acute renal insufficiency; no loading dose for colchicine due to high rates of renal insufficiency in elderly patients

REFERENCES

ADDITIONAL READING

CODES

ICD10
- M11.20 Other chondrocalcinosis, unspecified site
- M11.269 Other chondrocalcinosis, unspecified knee
- M11.29 Other chondrocalcinosis, multiple sites

CLINICAL PEARLS
- Suspect CPPD in arthritis cases that do not follow a pattern typical of degenerative joint disease.
- Perform arthrocentesis to confirm diagnosis.
- If septic arthritis is suspected, treat empirically with antibiotics while awaiting culture.
- NSAIDs are preferred pharmacologic treatment for acute flare.
- Oral steroids are useful if NSAIDs are contraindicated.
- Intra-articular steroids can be used if septic arthritis has been excluded.
BASICS

DESCRIPTION

- A chronic, inflammatory disorder most commonly characterized by cutaneous erythematous plaques with silvery scale. It is a complex immune-mediated disorder that results from a polygenic predisposition in the setting of environmental triggers. It is associated with relapsing flares related to systemic, psychological, infectious, and environmental factors. A skin disease with multiple phenotypic variations and degrees of severity.

- Clinical phenotypes
  - Plaque (vulgaris): most common variant (~80% of cases); well-demarcated, red plaques with thick, silvery scale; symmetrically distributed most commonly on the scalp, extensor surfaces of extremities, and trunk
  - Guttate: <2% of psoriasis patients, usually in patients <30 years of age; presents abruptly with 1- to 10-mm droplet-shaped pink erythematous papules with fine scale over trunk and extremities; often preceded by group A β-hemolytic streptococcal infection 2 to 3 weeks prior
  - Inverse: affects intertriginous areas and flexural surfaces; pink-to-red plaques with minimal scale; absence of satellite pustules distinguishes it from candidiasis although may coexist.
  - Erythrodermic: generalized erythema and scaling, affecting 90% of body surface area (BSA) or more; associated with desquamation; hair loss; nail dystrophy; and systemic symptoms such as fever, chills, malaise, lymphadenopathy, and/or high-output cardiac failure; usually requires hospital admission for management of dehydration, electrolyte abnormalities, and risk of infection
  - Pustular: sterile pustules; several forms including generalized pustular psoriasis, localized pustular psoriasis, and impetigo herpetiformis (in pregnancy); generalized type can result in life-threatening bacterial superinfections, sepsis, and dehydration if left untreated.
  - Nail disease: pitting, oil spots, and onycholysis; nails involved in up to 50% of patients with psoriasis with lifetime incidence of 80–90%; increased association with psoriatic arthritis
  - Psoriatic arthritis: 5–30% of patients; most commonly asymmetrical oligoarthritis involving the hands and feet

EPIDEMIOLOGY

Incidence
Predominant sex: male = female; predominant age: two peaks of incidence between the ages of 20 to 30 years and 50 to 60 years

Prevalence
- 2–4%—similar prevalence in all races in the United States
- Estimated 125 million affected worldwide (1)

ETIOLOGY AND PATHOPHYSIOLOGY
Psoriasis is a complex immune-mediated disorder with interactions between dendritic cells, T lymphocytes, neutrophils, and keratinocytes. It is considered a TH1- and TH17-driven disease
with numerous cytokines including TNF-α, interferon-γ, IL-12, IL-17, and IL-23 playing pathogenic roles resulting in an inflammatory, hyperproliferative state.

**Genetics**
- Genetic predisposition (polygenic)
- 40% have psoriasis in a first-degree relative.
- Multiple susceptibility loci contain genes involved in immune system regulation (e.g., psoriasis susceptibility [PSORS1] locus on chromosome 6p21; polymorphisms in the IL-12/IL-13 receptor, the p40 subunit of IL-12 and IL-23, and the p19 subunit of IL-12) (2).
- HLA-Cw6 is most strongly correlated with early onset psoriasis.

**RISK FACTORS**
- Family history
- Obesity (may contribute to more severe disease)
- Local trauma; local irritation (Koebner phenomenon)
- HIV
- Streptococcal infection
- Mental stress (may contribute to exacerbation)
- Medications (lithium, antimalarials, β-blockers, interferon, TNF-α inhibitors, withdrawal of steroids)
- Smoking
- Alcohol

**GENERAL PREVENTION**
Avoid triggers, including trauma, sunburns, smoking, and exposure to certain medications, alcohol, and stress; weight loss if obese

**COMMONLY ASSOCIATED CONDITIONS**
- Psoriatic arthritis
- Seborrheic dermatitis
- Obesity, metabolic syndrome, diabetes, chronic kidney disease
- Cardiovascular disease, atherosclerotic disease
- Nonalcoholic fatty liver disease (NAFLD)
- Other autoimmune conditions: Crohn disease, ankylosing spondylitis
- Psychiatric/psychological: depression, suicide, emotional burden/anxiety, alcohol abuse

**DIAGNOSIS**

**HISTORY**
- May include: sudden onset of clearly demarcated, erythematous plaques with overlying silvery scales or exacerbation of chronic plaques, especially on extensor surfaces and scalp. Typically no or mild pruritus. Triggers may include recent streptococcal infection or trauma.
- Family history of similar condition

**PHYSICAL EXAM**
- Well-demarcated salmon pink-to-red erythematous papules and plaques with silvery scale
- Distribution favors scalp, auricular conchal bowls, and postauricular area, extensor surface of
extremities, especially knees and elbows, umbilicus, lower back, intergluteal cleft, and nails
- Nail findings: pitting, oil spots, onycholysis
- Auspitz sign: pinpoint bleeding with removal of scale
- Koebner phenomenon: new psoriatic lesions arising at sites of skin injury/trauma
- Woronoff ring is a pale blanching ring that may be seen around a psoriatic lesion
- Sebopsoriasis: Psoriasis can overlap with seborrheic dermatitis as greasy scales on the scalp, eyebrows, nasolabial folds, postauricular, and presternal areas.

**DIFFERENTIAL DIAGNOSIS**
- Plaque: seborrheic dermatitis (may coexist), nummular eczema, atopic dermatitis, contact dermatitis, lichen simplex chronicus (may coexist), tinea, pityriasis rubra pilaris, dermatomyositis, squamous cell carcinoma in situ, reactive arthritis, pityriasis rosea, lichen planus, lichen sclerosis et atrophicus
- Guttate: pityriasis rosea, pityriasis lichenoides chronica, secondary syphilis, small plaque parapsoriasis
- Inverse: cutaneous candidiasis, tinea, seborrheic dermatitis, contact dermatitis
- Pustular: subcorneal pustulosis, acute generalized exanthematous pustulosis, folliculitis
- Erythrodermic: cutaneous T-cell lymphoma, drug-induced erythroderma, pityriasis rubra pilaris

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Clinical diagnosis based on history and physical exam. Labs generally not needed, although KOH to rule out tinea helpful, especially in inverse psoriasis. Consider skin biopsy if diagnosis unclear. Consider x-rays if complaints of joint pain to evaluate for psoriatic arthritis.

**Diagnostic Procedures/Other**
- Psoriasis Area and Severity Index (PASI) evaluates overall severity and BSA involvement.
- Dermatology Life Quality Index (DLQI)

**Test Interpretation**
Biopsy findings: thickening of the stratum corneum (hyperkeratosis) with retention of nuclei (parakeratosis); elongation, thickening, and clubbing of rete ridges; dilated tortuous capillary loops in the dermal papillae; perivascular lymphocytic infiltrate, Munro microabscesses: neutrophils in stratum corneum

**TREATMENT**

**GENERAL MEASURES**
Adequate topical hydration (emollients); avoid triggers; weight loss

**MEDICATION**

**First Line**
- Mild-to-moderate disease
  - Emollients: petrolatum/ointments to maintain skin hydration and minimize pruritus and risk of koebnerization
  - Topical corticosteroids
- Anti-inflammatory, antiproliferative, immunosuppressive, and vasoconstrictive effects
- Local side effects: skin atrophy, hypopigmentation, striae, acne, folliculitis, and purpura
- Systemic side effects: Risk is higher, with higher potency formulations used over a large surface for a prolonged period; Pregnancy Category C
- Applications are typically twice daily until lesions flatten/resolve and then taper to PRN use for maintenance.
- Scalp: high potency in solution/foam vehicle; shampoos and sprays also available
- Face, intertriginous areas, infants: low-potency corticosteroids: 1% hydrocortisone
- Adult initial therapy: medium-potency corticosteroids daily: 0.1% mometasone or triamcinolone; strong-potency corticosteroids: 0.05% betamethasone or fluocinonide daily; superpotency corticosteroids: clobetasol, halobetasol; caution with use over 2 to 4 weeks; avoid occlusive dressings; reserved for recalcitrant plaques
- Vitamin D analogues: calcipotriene 0.005% cream daily to BID; good for plaque and also intertriginous zones; limits keratinocyte hyperproliferation; may be highly effective for short-term control in combination with a superpotent corticosteroid; should not be used with products that can alter pH, such as topical lactic acid; local side effects: burning, pruritus, edema, peeling, dryness, and erythema; pregnancy Category C
- Topical retinoids: tazarotene 0.05% or 0.1% (Tazorac) daily; normalizes abnormal keratinocyte differentiation and diminishes hyperproliferation; may be combined with corticosteroids; side effects: local irritation, photosensitivity; pregnancy Category X
- Topical calcineurin inhibitors: Tacrolimus 0.1% or pimecrolimus 1% may be used as steroid-sparing agents, especially in facial and intertriginous areas.
- Comparison of topical therapies: Vitamin D analogues have slower onset of action than topical corticosteroids but longer disease-free periods for body plaques; for scalp, potent and superpotency steroids are more effective (3)[A].
- Combination of superpotent steroids and vitamin D analogues has better efficacy than either as monotherapy (4)[A].

Severe disease: may need combination therapy
- Light therapy: locally immunosuppressive and antiproliferative. UVB (broad/narrow band [BB, NB]) or PUVA: Treatment protocols are skin type dependent: mixed studies as to whether PUVA or NBUVB more effective; PUVA with GI SE, photosensitivity, and increased risk of nonmelanoma skin cancers
- Systemic therapies
- Methotrexate: immunosuppressive, blocks DNA synthesis; start with 5-mg test dose, then increase to 7.5 to 15.0 mg/week IV, PO, IM, or SC, and then increase 2.5 mg every 2 to 3 weeks, up to 25 mg; contraindicated in pregnancy and use caution in women of child bearing age; supplement with folic acid 1 mg/day to protect against side effects: hepatotoxicity, pulmonary toxicity, bone marrow suppression; baseline chest x-ray, monitor LFTs, renal function, CBC, testing for latent tuberculosis (TB); consider liver biopsy when cumulative dose reaches 3.5 to 4.0 g; avoid alcohol and medications that interfere with folic acid metabolism, including trimethoprim—sulfamethoxazole (Bactrim), NSAIDs, sulfamethoxazole, or hepatotoxic agents (e.g., retinoids).
- Cyclosporine: inhibits T-cell activation; start 2.5 mg/kg/day; if insufficient response after 4 weeks, increase by 0.5 mg/kg/day; additional dosage increases every 2 weeks (max dose: 5 mg/kg/day); pregnancy Category C; side effects: renal toxicity and hypertension, limit use to 6 months to 1 year: Monitor renal function, with Mg\(^2\) and K\(^+\), CBC, lipids,
Acitretin (Soriatane): systemic retinoid; start at 10 to 25 mg/day given with the main meal; effective for pustular psoriasis and as a maintenance therapy after stabilization with other agents; sometimes combined with UVB/PUVA; pregnancy Category X: pregnancy test before starting; two forms of contraception 1 month before, during, and for at least 3 years after treatment; avoid alcohol (may convert acitretin to etretinate); side effects: alopecia, xerosis, cheilitis, hepatotoxicity, hyperlipidemia, cataracts; monitor LFTs, renal function, lipid profile, CBC, regular eye exams.

Biologics: general guidelines: Screen for latent TB at baseline and yearly, hepatitis panel at baseline, avoid live vaccines; monitor CBC with differential, signs/symptoms of infections, heart failure, malignancy, drug-induced lupus, demyelinating disorder. Some concern for “biologic fatigue” phenomenon, or loss of PASI 75 over time, possibly due to antidrug antibodies. Each has been shown to be effective at 24 weeks with an NNT between 1 and 3. All should be considered effective first-line treatments (5)[A]; pregnancy Category B

- TNF-α inhibitors: Etanercept (Enbrel): Begin at 50 mg SC twice a week for 3 months, then maintenance of 50 mg/week. Adalimumab (Humira): Dosing starts at 80 mg SC for 1 week, then 40 mg SC every other week. Infliximab (Remicade): 5 mg/kg IV at weeks 0, 2, and 6; maintenance doses of 5 mg/kg every 8 weeks thereafter; adjust interval, as needed; anaphylaxis-like infusion reaction occurs in <1% of patients.
- IL-12/IL-23 antagonist: ustekinumab (Stelara): patients <100 kg: 45 mg SC at weeks 0 and 4 and then every 12 weeks; >100 kg: 90 mg can be given.
- IL-17 antagonists: secukinumab (Cosentyx): 300 mg SC on weeks 0, 1, 2, 3, and 4 and then every 4 weeks. Ixekizumab (Taltz): 160 mg on week 0, then 80 mg on weeks 2, 4, 6, 8, 10, and 12, and then 80 mg every 4 weeks. Brodalumab (Siliq): 210 mg SC on weeks 0, 1, 2 and then every 2 weeks.
- Phosphodiesterase-4 enzyme inhibitor: Apremilast (Otezla): 10 mg PO, titrate up by 10 mg/day on days 2 to 5 to maintenance dose of 30 mg BID starting on day 6. Routine lab monitoring not required. Most common SE are GI symptoms, depression; pregnancy Category C

Second Line
- Immunosuppressives: azathioprine, hydroxyurea, 6-thioguanine, fumaric acid esters
- Topicals: salicylic acid, anthralin, coal tar

ISSUES FOR REFERRAL
Psoriasis >20% of BSA, psoriatic arthritis, pustular psoriasis, severe extremity involvement, particularly hands and feet

SURGERY/OTHER PROCEDURES
Psoriasis and psoriatic medications can affect wound healing postoperatively; methotrexate: Monitor for postoperative infections; hold cyclosporine for 1 week before and after; some surgeons may prefer to hold therapy with biologics for up to 1 month before and after surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Generalized pustular psoriasis/erythrodermic psoriasis: rule out sepsis; restoration of barrier function of skin with cleaning and bandaging; intensive topical corticosteroid therapy (like wet wraps), systemic therapy, particularly medications with a quick onset such as oral cyclosporine; management of electrolytes
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Measure BSA involvement to determine if therapy is working; change therapy or add agent if no improvement is seen.

DIET
Well-balanced diet and exercise to limit cardiovascular risk factors and decrease risk of associated conditions, including obesity, metabolic syndrome, diabetes, and atherosclerosis

PATIENT EDUCATION
National Psoriasis Foundation: https://www.psoriasis.org; 800-723-9166

PROGNOSIS
Guttate form may be self-limited and remit after months; chronic plaque type is lifelong, with intermittent spontaneous remissions and exacerbations; erythrodermic and generalized pustular forms may be severe and persistent.

COMPLICATIONS
Psoriatic arthritis, generalized pustular psoriasis, erythrodermic psoriasis, comorbidities (cardiovascular disease, metabolic syndrome, etc.)

Arthritis, Psoriatic
CODES

ICD10
- L40.9 Psoriasis, unspecified
- L40.50 Arthropathic psoriasis, unspecified
- L42 Pityriasis rosea

CLINICAL PEARLS

Chronic lifelong inflammatory skin condition with remissions and exacerbations; set realistic expectations with patient. Disease burden not limited to skin. If one medication does not work, use/combine with another agent. Control cardiovascular risk factors, patients with psoriasis have a higher risk of cardiovascular disease.
PSYCHOSIS
Matthew J. Filippo, DO  Courtney Heim, DO

BASICS
DESCRIPTION
A disorder where thoughts and emotions are significantly impaired (i.e., a loss of contact with reality). Seen in schizophrenia, affective disorders, bipolar disorder, depression, substance use, medical problems, delirium, and dementia; symptoms include the following:
- Positive symptoms: hallucinations and delusions (fixed false beliefs not typical of cultural background)
- Negative symptoms: anhedonia, poverty of speech, lack of motivation, social withdrawal, affective blunting
- Cognition: poor working memory, information processing, difficulty with attention, disorganized speech and/or behavior

EPIDEMIOLOGY
Incidence
The incidence of schizophrenia (the number of new cases annually) is about 1.5 per 10,000 people.

Prevalence
- Schizophrenia: peak onset 18 to 25 years in males; 25 to 35 years in females
- 1% of the U.S. population; similar percentage worldwide; 1:1 male–female ratio
- Delusional disorder: 0.3% of population, bipolar: 1–3% of population, unipolar depression: up to 20% prevalence

ETIOLOGY AND PATHOPHYSIOLOGY
- Stems from many causes, including psychiatric, medical, and/or substance use
- Positive symptoms relate to excessive dopaminergic activity in the mesolimbic pathway.
- Negative symptoms relate to diminished dopaminergic activity in mesocortical pathway.
- Glutamate, steroids, cortisol, inflammation, and developmental abnormalities are likely involved and active areas of research.

Genetics
Schizophrenia: 50% concordance for monozygotic twins, little or no shared environmental effect; multiple candidate genes involved

RISK FACTORS
Substance abuse (particularly cannabis or synthetics), family history of psychosis, lower socioeconomic status

GENERAL PREVENTION
Community interventions for early detection and treatment of prodromal symptoms show promise; research currently exploring use of omega-3 fatty acids and anti-inflammatories, which may prevent prodromal progression to schizophrenia
COMMONLY ASSOCIATED CONDITIONS
- Associated with metabolic syndrome, autonomic dysfunction, sudden cardiac death, and cancer mortality: particularly breast and lung cancer
- Substance abuse disorders, including nicotine dependence

DIAGNOSIS
Rule out delirium: Psychosis should not have fluctuating consciousness/reduced clarity of awareness.

HISTORY
- Delusions (fixed false beliefs): persecutory (being monitored), bizarre (involving impossible states), somatic (fixed belief in nonexistent illness), referential (getting special messages or thoughts inserted/deleted by others), grandiose (belief that one has special powers)
- Hallucinations: auditory, visual, tactile, gustatory, olfactory
- Bipolar depression, unipolar depression, and dementia are associated with psychosis. Screen for symptoms of these.
- Screen for toxidromes of drugs of abuse and for history of epileptiform activity.
- Suicidality: higher risk with comorbid depression/mania, previous attempts, drug abuse, agitation/akathisia, poor adherence

PHYSICAL EXAM
- Mental status exam: disorganized speech, behavior, and/or thought process; thought blocking; response latency; blunted or flat affect; often have negative symptoms, including social withdrawal, lack of initiative, poverty of thought, and/or positive symptoms such as auditory and visual hallucinations
- Pay attention to focal neurologic symptoms, antipsychotic-induced parkinsonism, tardive dyskinesia, and akathisia.
- May present with catatonia: ranging from lack of movement to extreme excitement, posturing, mutism, grimacing, waxy flexibility

DIFFERENTIAL DIAGNOSIS
- Schizophrenia: positive symptoms (psychosis) and negative symptoms (flat affect), prodrome of social withdrawal, cognitive impairment; schizophreniform disorder: psychotic/prodromal symptoms in <6 months; schizoaffective disorder: manic/depressive mood disorder with psychosis that persists even when euthymic; schizotypal personality disorder: no true psychosis but distance in relationships and odd beliefs; delusional disorder: nonbizarre delusion (e.g., erotomanic, grandiose, jealous, persecutory, somatic), no negative/mood symptoms
- Mood disorder with psychotic features: can occur in mania or depression. Delusions often mood congruent; psychosis remits when mood improves.
- Substance-induced psychosis: alcohol and benzodiazepine withdrawal, intoxication with cocaine, bath salts, PCP, cannabis, synthetic cannabinoids, MDMA, amphetamines, hallucinogens, and alcohol; may persist beyond acute intoxication
- Borderline personality disorder: During extreme stress, patients often experience auditory/visual hallucinations (psychosis NOS).
- Posttraumatic stress disorder: psychosis associated with traumatic recollections; often visual
hallucinations (vs. more auditory in schizophrenia)

- Psychosis due to general medical condition: delirium, stroke, infection, collagen vascular disease, head injury, tumor, interictal, porphyria, syphilis, and so forth
- Medication-induced psychosis: common causes: steroids, l-dopa, anticholinergics, antidepressants in bipolar patients, interferon, digoxin, stimulants

**DIAGNOSTIC TESTS & INTERPRETATION**

Labs: CBC, CMP, LFTs, thyroid-stimulating hormone (TSH), rapid plasma reagin (RPR), HIV, ANA, ESR, vitamin B₁₂, 25-hydroxy-vitamin D, urinalysis, UDS

**Initial Tests (lab, imaging)**

- Neuroimaging: not necessary for diagnosis but may consider CT scan or MRI to evaluate for medical cause of symptoms (especially with focal neurological deficits and first break or new onset in the elderly). Schizophrenia is associated with enlarged lateral ventricles, reduced gray matter, and symmetry.
- Consider EKG if patient has a cardiac history, is above age 50, and may require antipsychotic therapy. Many antipsychotics can prolong QTc interval, particularly ziprasidone, iloperidone, and IV haloperidol. Aripiprazole may shorten QTc.

**Follow-Up Tests & Special Considerations**

- Consider Wilson disease, porphyria, metachromatic leukodystrophy, and inflammatory conditions.
- Consider lumbar puncture if unable to distinguish from delirium and/or unexplained rapid-onset psychosis.
- Consider electroencephalogram (EEG) for partial complex seizures and psychosis associated with preictal and postictal events.

**TREATMENT**

Before antipsychotic treatment: Screen for metabolic syndrome. Baseline fasting lipid panel and glucose, HgbA₁c, CBC, CMP, LFTs, weight, waist circumference, AIMS testing. Continue monitoring with long-term use (1)[B].

**GENERAL MEASURES**

Ensure safety of person and environment and rule out medical causes of psychosis particularly delirium. Many psychotic patients presenting to the hospital may require inpatient care for acute stabilization

**MEDICATION**

- Antipsychotics are mainstay of treatment (1)[B].
- Classified as typical versus atypical. Dopamine-2 (D₂) antagonists with varied affinity for the receptor. Atypicals also block serotonin 5-HT2A receptors. Help positive symptoms more than negative. Nonspecific effect on agitation begins early; antipsychotic effect takes 1 to 6 weeks.
- For mania with psychotic features, a mood stabilizer may be used with an antipsychotic.
- For major depression with psychotic features, antidepressant and antipsychotic medications yield better response rate than either medication alone. In delirium, must treat underlying cause; may not require antipsychotic therapy
Side effects
- Acute dystonia: benztropine 1 to 3 mg IM/IV then 0.5 to 2.0 mg BID–TID or diphenhydramine 50 to 100 mg IM/IV BID–TID max 400 mg/day, NTE 25 mg/min
- Parkinsonism: Lower antipsychotic dose; switch to atypical (particularly, quetiapine, olanzapine, or clozapine) and/or add benztropine 0.5 to 2.0 mg PO BID–TID, diphenhydramine 25 to 50 mg BID–TID.
- Akathisia: intense restlessness, especially legs. Lower antipsychotic dose; treat with β-blocker, anticholinergic, or benzodiazepine; may switch to antipsychotic with lower akathisia risk such as quetiapine, olanzapine, iloperidone, or clozapine
- Tardive dyskinesia: seen in ~32.4% of those treated long term with typicals, 13.1% treated with atypicals. Switch to clozapine or quetiapine. If cannot, minimize dose. Symptomatic treatment has been tried with low-dose benzodiazepines, botulinum toxin, anticholinergics, and VMAT-2 inhibitors such as FDA-approved valbenazine and deutetrabenazine. AIMS exam is gold standard for detecting tardive dyskinesia.
- Neuroleptic malignant syndrome: potentially fatal; rigidity, tremor, fever, autonomic instability, mental status changes; discontinue neuroleptic; ICU; volume resuscitation; cooling blankets; no anticholinergics/antihistaminics; consider dantrolene, amantadine, bromocriptine, and electroconvulsive therapy (ECT).
- Metabolic syndrome, sudden cardiac death (risk higher IM/IV droperidol, IV haloperidol), stroke, heart failure, PNA (elderly), pulmonary embolus

First Line
- Benefits of atypical antipsychotics; lower risk of extrapyramidal symptoms (quetiapine, olanzapine, iloperidone, or clozapine) and dyskinesias (clozapine, quetiapine); possibly more effective for negative symptoms
- Greater risk of weight gain, new-onset diabetes, and hyperlipidemia with olanzapine and clozapine compared with typicals and other atypicals
- Acute psychotic agitation: olanzapine 5 to 10 mg IM with up to three 10-mg injections over a 24-hour period; do not administer concurrently with benzodiazepines; ziprasidone 10 mg IM q2h or 20 mg q4h; NTE 40 mg/day; aripiprazole IM has been discontinued; haloperidol 5 mg +/- lorazepam 2 mg IM, can be given with 1 mg IM benztropine, NTE 20 mg haloperidol, and 8 mg lorazepam per day.
- Psychosis in schizophrenia
  - Olanzapine: Start 5 to 10 mg at bedtime; target dose 5 to 20 mg/day within 2 days and up to 40 mg/day in treatment-refractory schizophrenia. More likely weight gain, hyperlipidemia, and hyperglycemia than other oral atypicals except clozapine; may have lower rates of discontinuation and rehospitalization than several other atypicals but likely not more efficacy than clozapine; sedation initially; drug metabolism increased up to 50% by tobacco use
  - Quetiapine: Start 25 mg BID, increase 25 to 50 mg q8–12h days 2 and 3, up to 3, to 400 mg in divided doses by day 4. Can then increase 50 to 100 mg/day, NTE 800 mg/day divided BID–TID; less risk of parkinsonism, useful in Parkinson psychosis; more weight gain than others; sedation, restless legs syndrome; gradual titration tolerated better. Quetiapine XR: can start 300 mg/day. Dose increase ≥1 day up to 300 mg/day. Target dose is 300 to 800 mg.
  - Risperidone: Start 1 to 2 mg/day; target dose of 2 to 8 mg/day to be reached over 1 to 2 weeks; doses >6 mg rarely more effective and higher risk of parkinsonism; higher risk of
prolactinemia/parkinsonism due to D₂ blockade
- Paliperidone: Start 3 to 6 mg/day; target dose 6 to 12 mg/day; titrate over 1 to 2 weeks. Higher risk of prolactinemia/parkinsonism than others; minimal hepatic metabolism, ideal for hepatic impairment
- Ziprasidone: Start 20 to 40 mg PO BID with food (at least 500 calories), with target dose of 100 to 160 mg/day in divided doses over 2 weeks; prolongs QTc; less likely to cause weight gain than other atypicals; higher risk of akathisia/parkinsonism
- Aripiprazole: Start 10 to 15 mg/day, may increase up to 30 mg/day over 1 to 2 weeks; less weight gain but higher rates of akathisia; can lower QTc
- Asenapine: Start 5 mg at bedtime or BID sublingually, increase to 10 mg BID if needed over 1 to 2 weeks; less weight gain than some, higher rates of akathisia/parkinsonism; sedation, orthostatic hypotension, numb tongue, nausea, bad taste
- Lurasidone: Start 20 to 40 mg QD with food (at least 350 calories), increase up to max of 160 mg at bedtime if needed over 2 to 4 weeks. Less weight gain than some but higher rates of akathisia/parkinsonism; not antihistaminic but α-blocking sedation and serotonergic nausea
- Iloperidone: Start 1 mg BID, may increase by 2 mg daily, but slower can be better due to significant orthostasis. Increase to max 12 mg BID; little akathisia/parkinsonism, less weight gain but slower efficacy due to long titration, orthostasis, sedation
- Brexpiprazole: Start 1 mg daily for first 4 days, 2 mg QD days 5 to 7, can increase dose up to 4 mg/day based on response and tolerability. Lower rates of akathisia than aripiprazole but higher rates than others; less weight gain than others
- Cariprazine: Start at 1.5 mg QD, can be increased to 3 mg QD on day 2, dosed up to 6 mg daily based on tolerability and response; in 6-week study, similar to placebo in changes of fasting glucose, cholesterol, triglycerides, and showed 0.8 to 1.0 kg weight increase

Geriatric Considerations
Increased risk of death compared to placebo when antipsychotics are used in the elderly with dementia. Pimavanserin has recently been approved for hallucinations and delusions associated with Parkinson disease psychosis.

Second Line
Clozapine: more effective for reducing symptom SHADEs, preventing relapse, decreasing tardive dyskinesia, and decreasing suicidality than other antipsychotics. Second line given risk of fatal agranulocytosis. Single national registry (clozapine Risk Evaluation and Mitigation Strategy [REMS]) for all patients on clozapine, updated guidelines in 2015 requiring CBC to monitor absolute neutrophil count weekly for first 6 months, then every 2 weeks for 6 months, and then every 4 weeks. More weight gain, hyperlipidemia, hyperglycemia, seizures, myocarditis, pulmonary embolus, and sedation but low rate of parkinsonism, tardive dyskinesia; useful in treatment-refractory psychosis and in Parkinson disease psychosis. Despite association with more weight gain than other antipsychotics, clozapine and olanzapine do not appear to increase risk of cardiac and all-cause mortality. Drug metabolism increased up to 50% by tobacco use.
- Maintenance:
  - Consider switching to long-acting injectable (LAI) medications.

ADDITIONAL THERAPIES
Psychotherapy, vocational, art, and group are effective adjuvants to antipsychotics. [1][B].
COMPLEMENTARY & ALTERNATIVE MEDICINE
Vitamin treatments if there is a deficiency (common with folic acid, B₆, B₁₂, D), fish oil
supplements, glycine, diet. Early studies show CBD may have efficacy as adjunctive treatment.
This should not be confused with THC, which can precipitate psychosis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: at risk for harm to self or others; extreme functional
  impairment; unable to care for self; new-onset psychosis
- Discharge criteria: when not danger to self or others AND adequate outpatient follow-up in
  place

ONGOING CARE
Medication management, psychotherapy. Cognitive behavioral therapies can be very effective in
psychosis.

FOLLOW-UP RECOMMENDATIONS
Close follow-up for inpatient discharge (high risk for suicide), use therapy, exercise, smoking
cessation, AIMS testing q3–6mo

Patient Monitoring
- For EPS: when starting you should evaluate weekly until medication dose is stable for at least
  2 weeks. Once stabilized, assess for EPS and TD at least every 6 (high potency) to 12 months.
- Lipids: check at baseline, 6 weeks, 3 months, and then at minimum annually.
- Fasting glucose or HbA1c: Check at baseline, 3 months, 12 months, and then annually.
- Diet, smoking, blood pressure, weight: Check at baseline, 6 weeks, 3 months, and then
  quarterly.

DIET
- Recommended to follow portion control with emphasis on fresh fruits or vegetables, whole
  grains, and lean meats.
- Avoid alcohol and sugar-sweetened beverages.

PATIENT EDUCATION
National Alliance on Mental Illness: https://www.nami.org/

PROGNOSIS
Schizophrenia: fluctuating course; 70% first-episode psychosis patients improve in 3 to 4
months, 20–40% will attempt suicide, and 7% will die of suicide.

COMPLICATIONS
Metabolic disturbances including weight gain, hyperlipidemia, HTN, and DM (secondary to
antipsychotic medications, sedentary lifestyle, and smoking). Life expectancy reduced by more
than a decade compared to general population (largely mediated by heart disease).

SEE ALSO

Delirium; Schizophrenia

CODES

ICD10
- F29 Unsp psychosis not due to a substance or known physiol cond
- F20.9 Schizophrenia, unspecified
- F39 Unspecified mood [affective] disorder

CLINICAL PEARLS
- Antipsychotics mainstay of treatment; lead to decreased all-cause mortality in adherent patients
- Clozapine and LAIs may increase adherence.
BASICS

DESCRIPTION

- Pulmonary arterial hypertension (PAH) is a category of pulmonary hypertension (PH) characterized by abnormalities in the small pulmonary arteries (precapillary PH) that produce increased pulmonary arterial pressure (PAP) and vascular resistance, eventually resulting in right-sided heart failure. PAH is a progressive disorder associated with increased mortality.
  - Previously, PH was classified as primary PH (without cause, now idiopathic IPAH) or secondary PH (with cause or associated condition); now, it is clear that some types of secondary PH closely match primary PH (IPAH) in their histology, natural history, and response to treatment. Therefore, WHO classifies PH into five groups based on mechanism, with PAH as group 1 in this classification.
  - PAH is diagnosed by right-heart catheterization and defined by a mean PAP ≥25 mm Hg at rest when other groups of PH are ruled out; pulmonary capillary wedge pressure ≤15 mm Hg (excludes PH owing to left heart disease; i.e., group 2 PH)
  - Mild or absent chronic lung disease or other causes of hypoxemia (excludes PH owing to lung disease or hypoxemia; i.e., group 3 PH)
  - Absent venous thromboembolic disease (excludes chronic thromboembolic PH [CTEPH]; i.e., group 4 PH)
  - Absent systemic disorder (like sarcoidosis), hematologic disorders (like myeloproliferative disease), and metabolic disorders (like glycogen storage disease) (excludes group 5 PH)

- PAH is divided into the following main categories:
  - Idiopathic: sporadic, with no family history or risk factors
  - Heritable: IPAH with mutations or familial cases with or without mutations
  - Drug or toxin induced: mostly associated with anorectics (e.g., fenfluramine), rapeseed oil, L-tryptophan, dasatinib (Bcr-Abl tyrosine kinase inhibitor), and illicit drugs such as methamphetamine and cocaine
  - Associated: connective tissue diseases (e.g., systemic lupus erythematosus, rheumatoid arthritis, scleroderma), HIV infection, portal hypertension (HTN), congenital heart disease, schistosomiasis (chronic hemolytic anemia added to group 5 PH—unclear/multifactorial mechanisms) (1)
  - Pulmonary veno-occlusive disease (PVOD) and/or pulmonary capillary hemangiomatosis (PCH) and persistent PH of the newborn (PPHN) are classified as separate categories due to more differences than similarities with PAH.
    - PVOD and/or PCH: rare cause of PH characterized by extensive diffuse occlusion of the pulmonary veins (unlike PAH, which involves the small muscular pulmonary arterioles)

EPIDEMIOLOGY

- Age: can occur at any age; mean age 37 years
- Sex (IPAH): female > male (female:male ratio ranges from 1.7 to 4.8:1.0)

Incidence
Overall PAH: 5 to 52 cases per million
- IPAH: low, ~2 to 6 per million
- Drug-induced PAH: 1/25,000 with >3 months of anorectic use
- HIV associated: 0.5/100
- Portal HTN associated: 1 to 6/100
- Scleroderma associated: 6–60%

**Prevalence**
- PAH: ~15 to 50 cases per million
- IPAH: ~6 cases per million

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Pulmonary: Inflammation, vasoconstriction, endothelial dysfunction, and intimal proliferation causing remodeling of pulmonary arteries produced by increased cell proliferation and reduced rates of apoptosis lead to obstruction.
- Cardiovascular: Right ventricular hypertrophy (RVH), eventually leading to right-sided heart failure and right ventricular (RV) ischemia due to reduced right coronary artery flow, causes RV remodeling associated with PAH.
- IPAH: by definition, unknown. True IPAH is mostly sporadic or sometimes familial in nature.
- Pulmonary arteriolar hyperactivity and vasoconstriction, occult thromboembolism, or autoimmune (high frequency of antinuclear antibodies)

**Genetics**
- 75% of heritable PAH (HPAH) cases and 25% of IPAH cases have mutations in BMPR2 (autosomal dominant).
- Mutations in ALK1 and endoglin (autosomal dominant) also are associated with PAH.

**RISK FACTORS**
- Female sex
- Previous anorectic drug use
- Recent acute pulmonary embolism
- First-degree relatives of patient with familial PAH

**COMMONLY ASSOCIATED CONDITIONS**
See associated PAH, earlier discussed.

**DIAGNOSIS**
Symptoms of PAH are nonspecific, which can lead to missed or delayed diagnosis of this serious disease.

**HISTORY**
Dyspnea, weakness, syncope, dizziness, chest pain, palpitations, lower extremity edema

**PHYSICAL EXAM**
- Pulmonary component of S₂ (at apex in >90% of patients)
- RV lift
- Early systolic click of pulmonary valve
Pansystolic murmur of tricuspid regurgitation
Diastolic murmur of pulmonic insufficiency (Graham Steell murmur)
RV $S_3$ or $S_4$
Edema as jugular vein distention, ascites, hepatomegaly, or peripheral edema

DIFFERENTIAL DIAGNOSIS
Other causes of dyspnea:
- Pulmonary parenchymal disease such as chronic obstructive pulmonary disease, interstitial lung disease or restrictive lung disease
- Pulmonary vascular disease such as pulmonary thromboembolism
- Cardiac disease such as cardiomyopathy
- Other disorders of respiratory function such as sleep apnea

DIAGNOSTIC TESTS & INTERPRETATION
- Echocardiography (ECG): RVH and right axis deviation, or RV strain (increased P wave amplitude, incomplete right bundle branch block pattern, an R-to-S ratio > 1 in lead V1)
- Pulmonary function testing: reduced diffusion capacity
- Arterial blood gas: arterial hypoxemia, hypocapnia
- Ventilation/perfusion (V/Q) scan: Look for proximal pulmonary artery emboli and CTEPH; rule out group 4 PH.
- Exercise test: reduced maximal $O_2$ consumption, high-minute ventilation, low anaerobic threshold, increased $PO_2$ alveolar–arterial gradient; correlation to severity of disease with 6-minute walk distance (6MWD) test
- Antinuclear antibody positive (up to 40% of patients)
- LFTs: Evaluate for portopulmonary HTN as a complication of chronic liver disease.
- HIV test, thyroid function tests, sickle cell disease screening
- Elevated brain natriuretic peptide (BNP) and N-terminal-proBNP may be useful for early detection of PAH in young, otherwise healthy patients with mild symptoms. It can also be used to assess disease severity and prognosis.
- Chest radiograph
  - Prominent central pulmonary arteries with peripheral hypovascularity of pulmonary arterial branches
  - RV enlargement is a late finding.
- Echo Doppler
  - Should be performed with suspicion of PAH; echo suggests, but does not diagnose, PAH; most commonly used screening tool
    - Estimates mean PAP and assesses cardiac structure and function, excludes congenital anomalies
    - Right atrial and ventricular enlargement; tricuspid regurgitation
    - Important to rule out underlying cardiac disease such as atrial septal defect with secondary PH or mitral stenosis
- In patients at risk for HPAH, screen for gene mutations BMPR2.
- Polysomnography: for suspected symptoms of obstructive sleep apnea

Diagnostic Procedures/Other
- Pulmonary angiography
  - Should be done if V/Q scan suggests CTEPH
Use caution; can lead to hemodynamic collapse; use low osmolar agents, subselective angiograms.

- Right-sided cardiac catheterization (gold standard for diagnosis of PAH)
- Essential to confirm diagnosis and determine severity and prognosis by measuring PAPs and hemodynamics
  - Rule out underlying cardiac disease (e.g., left-sided heart disease) and assess response to vasodilator therapy.
- Lung biopsy: not recommended unless primary pulmonary parenchymal disease exists
- 6MWD: classifies severity of PAH and estimates prognosis

### TREATMENT

- Treat underlying diseases/conditions that may cause PAH to relieve symptoms and improve quality of life and survival.

  - Reasonable goals of therapy include the following:
    - Modified NYHA FC I or II
    - ECG/CMR of normal/near-normal RV size and function
    - Hemodynamic parameters showing normalization of the RV function (RAP <8 mm Hg and Cardiac Index (CI) >2.5 to 3.0 L/min/m²)
    - 6MWD of >380 to 440 m
    - Cardiopulmonary exercise testing, including peak oxygen consumption of >15 mL/min/kg and EqCO₂ <45 L/min
    - Normal BNP levels (2)[C]

### GENERAL MEASURES

- Supervised exercise training (3)[A]
- Psychosocial support (3)[C]
- Avoid strenuous physical activity (3)[C].
- Avoid pregnancy (3)[C].
- Influenza and pneumococcal immunization (3)[C]
- Oxygen—maintain arterial blood O₂ pressure >60 mm Hg (3)[C]

### MEDICATION

- Acute vasodilator test during heart catheterization for all patients who are potential candidates for long-term oral calcium channel blocker (CCB) therapy (3)[C]
  - Screens for pulmonary vasoreactivity/responsiveness using inhaled nitrous oxide; epoprostenol (IV) or adenosine (IV): Positive response may be a prognostic indicator.
  - Contraindicated in right-sided heart failure or hemodynamic instability
- Chronic vasodilator therapy
  - If IPAH with positive response to acute vasodilator test (a fall in mean PAP of ≥10 mm Hg and to a value <40 mm Hg, with unchanged/increased cardiac output), use CCBs.
    - Adequate response confirmed after 3 to 4 months of treatment
    - ~13% will initially respond. Long-term clinical response to CCB therapy is small (~7%) (3)[C].
    - CCBs include nifedipine (long acting), diltiazem, and amlodipine.
    - Avoid verapamil due to its significant negative inotropic effect.
CCBs are contraindicated in patients with a cardiac index of <2 L/min/m² or a right atrial pressure >15 mm Hg if PAH with negative response to acute vasodilator test or worsening on therapy; specific vasodilator choice based on risk stratification (3)[C]

- Nonresponders to acute vasoreactivity who are in WHO-FC II should be treated with an oral compound (3)[B].
- Nonresponders who remain or progress to WHO-FC III should be considered for treatment with any approved PAH drugs (3)[B].
- Continuous IV epoprostenol is recommended as first-line therapy for WHO-FC IV PAH due to survival benefit (NNT = 5) (3)[A].
- In case of inadequate clinical response, sequential combination therapy should be considered. Therapy includes ERA plus a phosphodiesterase type 5 (PDE5) inhibitor or a prostanoid plus ERA or a prostanoid plus a PDE5 inhibitor (3)[A].
- WHO-FC II PAH–approved drugs: ambrisentan, bosentan, macitentan, riociguat, sildenafil, tadalafil (3)[B]
- WHO-FC III PAH–approved drugs: ambrisentan, bosentan, epoprostenol (IV), macitentan, riociguat, sildenafil, tadalafil, treprostinil (SC, inhaled) (3)[B]
- WHO-FC IV PAH–approved drugs: epoprostenol (IV) (3)[A]

Drug classes:
- Prostacyclins: improve exercise capacity, cardiopulmonary hemodynamics: epoprostenol (IV), treprostinil (IV, SC, or inhaled), iloprost, beraprost
- Prostacyclin IP: receptor agonist—selexipag
- Endothelin receptor antagonists: improve exercise capacity; reducing mortality has been noted (4)[A]: bosentan (PO), ambrisentan (PO), macitentan. Pregnancy Category X; monitor LFTs monthly.
- PDE5 inhibitor: suggested improvement in exercise capacity, cardiopulmonary hemodynamics, and symptoms (3)[C]: sildenafil (PO), tadalafil (PO), vardenafil
- Guanylate cyclase stimulant: stimulators of the nitric oxide receptor, improves exercise capacity: riociguat (PO)

- Anticoagulation
  - Improved survival originally suggested in patients with IPAH only. Newer studies show some evidence for favorable effects of anticoagulation on survival in IPAH, HPAH, or PAH associated with anorexigens (3)[C].
  - Warfarin with international normalized ratio of 1.5 to 2.5 shows survival advantage in patients in multiple observational studies.
  - Contraindications: Avoid in patients with syncope or significant hemoptysis; consider drug interactions.
- Diuretics indicated in patients with RV volume overload (e.g., peripheral edema or ascites) (3) [B]
- Digoxin has little long-term data in PAH: used in RV failure and/or atrial dysrhythmias, increases cardiac output, and preserves RV contractility

**ISSUES FOR REFERRAL**

Refer to a pulmonologist and/or a cardiologist for further evaluation/treatment if PAH is suspected.

**SURGERY/OTHER PROCEDURES**

- Patients with documented large-vessel thromboembolic disease should be considered for
pulmonary thrombectomy.
- Balloon atrial septostomy for severe PAH with right-sided heart failure despite optimized medical therapy to relieve symptoms prior to lung transplant or as a treatment on its own
- Heart–lung or lung transplantation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Medical therapy is primarily palliative.
- Hospitalization with invasive monitoring is needed to screen vasodilator responsiveness and initiate vasodilator therapy.
- National registry has been established by the National Heart, Lung, and Blood Institute.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Pneumococcal and influenza vaccines
- Exercise: walking or low-level aerobic activity, as tolerated, once stable; respiratory training

**Patient Monitoring**
Frequently evaluate disease progression and therapeutic efficacy. Tests to measure treatment response include 6-minute walk test and cardiopulmonary exercise test.

**DIET**
Fluid and salt restrictions, especially with RV failure

**PATIENT EDUCATION**
Discuss prognosis, lifestyle changes, and all therapeutic options (including transplant).

**PROGNOSIS**
- Median survival is 2 to 3 years from diagnosis; 5-year survival rate is 34% (NIH registry); newer data show 5-year survival ~70% with new treatment.
- Mode of death: right-sided heart failure (most common), pneumonia, sudden death, cardiac death
- Poor prognostic factors
  - Rapid symptom progression
  - Clinical evidence of RV failure
  - WHO functional PAH class IV (or NYHA functional class III or IV)
  - 6MWD <300 m
  - Peak VO\textsubscript{2} during cardiopulmonary exercise testing <10.4 mL/kg/min
  - ECG with pericardial effusion, significant RV enlargement/dysfunction, right atrial enlargement
  - Mean right atrial pressure >20 mm Hg
  - Cardiac index <2 L/min/m\textsuperscript{2}
  - Elevated mean PAP
  - Significantly elevated BNP and NT-proBNP; other markers also show promise in predicting survival: RDW, GDF-15, interleukin-6, creatinine.
  - Scleroderma spectrum of diseases
COMPLICATIONS
• Thromboembolism, heart failure, pleural effusion, and sudden death
• Pregnancy should be avoided due to high maternal mortality (30–50%) and fetal wastage.

REFERENCES

ADDITIONAL READING

CODES
ICD10
• I27.0 Primary pulmonary hypertension
• I27.2 Other secondary pulmonary hypertension

CLINICAL PEARLS
• PAH involves abnormalities in the small pulmonary arteries (precapillary PH) which increase PAP and vascular resistance leading to right heart failure. Diagnosis is made by right heart catheterization.
• For positive vasodilator test, CCBs are the first-line agents to manage IPAH.
• For nonresponders, treatment depends on WHO-FC.
PULMONARY EMBOLISM
Umair Usman Khan, MD • Naureen Bashir Rafiq, MD

BASICS
Pulmonary embolism (PE) is an acute cardiovascular disorder that requires emergent medical attention due to its high early mortality rates. PE causes pulmonary vascular bed obstruction, which results in acute right ventricular failure, a life-threatening condition.

DESCRIPTION
- PE is the most serious presentation of venous thromboembolism (VTE).
- Classified based on severity:
  - Low-risk PE: acute and absence of clinical markers of adverse prognosis
  - Submassive PE: no systemic hypotension, but there is either myocardial necrosis (elevated troponin) or right ventricle (RV) dysfunction (RV dilation or systolic dysfunction on echocardiography [echo], RV/LV ratio >1 on computed tomography [CT], elevation of B-type natriuretic peptide [BNP] or N-terminal pro-BNP, or consistent electrocardiogram [ECG] changes)
  - Massive PE: hemodynamic instability with sustained hypotension; pulselessness; or persistent bradycardia, cardiogenic shock, acute manifesting RV failure

EPIDEMIOLOGY
Case fatality rates vary widely (1–60%); case fatality rate is approximately 11% at 2 weeks.

Incidence
- Approximately 30 to 80/100,000, with higher incidence in African Americans and lower in Asians; >100,000 cases annually in the United States
- Incidence increases with age, most occurring at 60 to 70 years of age.
- 250,000 hospitalizations per year in the United States, 10–60% in hospitalized patients
  - Highest risk for orthopedic and cancer patients
  - 1/1,000 pregnancies (including postpartum)

Prevalence
- Epidemiology is difficult to determine outside of the hospital setting because some patients with PE may remain asymptomatic, the first presentation of PE can be sudden death or diagnosis of PE is incidental.
- Within hospitalized patients:
  - 17.3% prevalence of PE in hospitalized adults who were admitted for first episode of syncope (between 2012–2014)
  - 2.5–23 per 10,000 patient prevalence of PE in Asian countries (China, India, Japan, Korea, Singapore) (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Venous stasis, endothelial damage, and changes in coagulation properties trigger thrombus.
- Causes increased pulmonary vascular resistance, impaired gas exchange, and decreased pulmonary compliance. RV failure due to pressure overload is usually the primary cause of death.
The most common source (85%) of PE is proximal lower extremity deep vein thrombosis.

**Genetics**
- Factor V Leiden: most common thrombophilia. 5.5% in Caucasian, 2.2% in Hispanics, 1.2% in African American, 0.5% in Asian; associated with 20% of VTE
- Prothrombin G20210A: 3% of Caucasians; rare in African American, Asian, and Native American; 6% in patients with VTE
- Rarely, deficiencies in protein C, S, and antithrombin

**RISK FACTORS**
- Older age, obesity, prolonged immobilization, surgery, major trauma, joint replacement, spinal cord injury, cancer, hormonal replacement therapy, pregnancy/puerperium, previous thrombosis, antiphospholipid syndrome, genetics
- Oral contraceptive most frequent risk factor in women.

**GENERAL PREVENTION**
- Low VTE risk: early ambulation after surgery, compression stockings, and intermittent pneumatic compression
- Hip or knee arthroplasty (high VTE risk): 10 or more days prophylaxis with low-molecular-weight heparin (LMWH), fondaparinux, apixaban, dabigatran, rivaroxaban, or low-dose unfractionated heparin (UFH)
- Spinal cord injury, hip fracture surgery, and trauma surgery (high VTE risk): 28 to 35 days with LMWH, fondaparinux, UFH, or vitamin K antagonists (VKA)
- Long-distance travel (>8 hours): hydration, walking, avoidance of constrictive clothing and frequent calf exercises, compression stockings below knee
- Patients with factor V Leiden, prothrombin G20210A with no previous thrombosis do not need prophylaxis.

**DIAGNOSIS**
- Establish a pretest probability based on clinical criteria.
  - Wells score
    - Clinical signs and symptoms of DVT +3
    - Alternative diagnosis is less likely than PE +3.
    - Heart rate >100 +1.5
    - Immobilization previous 4 weeks +1.5
    - Previous DVT/PE +1.5
    - Hemoptysis +1
    - Malignancy +1
    - D-dimer has very high negative predictive value, so if < 500 ng/ml, pulmonary embolism is ruled out.
  - Interpretation:
    - <2 points, low probability (obtain D-dimer)
    - 2 to points, moderate probability (obtain D-dimer but consider initiating anticoagulation)
    - >4 points, high probability (obtain spiral CT angiogram if patient is stable and initiate anticoagulation if no contraindications)
Wells and revised Geneva score were simplified.
- Wells score: Each predictor is +1; PE unlikely if 0 to 1, PE likely if >2.
- Geneva score: Each predictor is +1 except for heart rate >95 beats/min, which is +2; PE unlikely if 0 to 2 and PE likely if >3.

**HISTORY**
- Determine if the presentation is provoked or idiopathic. Approximately 30% of cases develop without identifiable risk factor.
- Bleeding risk (previous anticoagulation, history of bleeding, recent interventions/surgeries, liver disease, kidney disease)
- Sudden onset dyspnea (>85%), chest pain (>50%), cough (20%), syncope (14%), hemoptysis (7%)

**PHYSICAL EXAM**
- Dyspnea, syncope, hemoptysis, tachycardia, tachypnea, accentuated S2; pleuritic chest pain, pleural friction rub, rales
- Signs of DVT: leg swelling, tenderness, visible collateral veins
- Signs of RV failure: jugular vein distention, S3 or S4, systolic murmur at left sternal edge, hepatomegaly

**DIFFERENTIAL DIAGNOSIS**
- Pulmonary: pneumonia, bronchitis, pneumothorax, pneumonitis, chronic obstructive pulmonary disease exacerbation, pulmonary edema
- Cardiac/vascular: myocardial infarction, pericarditis, congestive heart failure, aortic dissection
- Musculoskeletal: rib fracture(s), chest wall pain

**DIAGNOSTIC TESTS & INTERPRETATION**
- D-dimer ELISA: In patients with low pretest probability, it can rule out PE if it is negative (high negative predictive value [NPV]). It is not diagnostic if positive (low positive predictive value [PPV]), and it is not helpful if pretest probability is intermediate or high.
- CBC, creatinine, aPTT and PT, ABG: In young patients with idiopathic, recurrent, or significant family history of VTE, consider hypercoagulable tests.
  - Do not test for protein C, S, factor VIII, or antithrombin in the acute setting.
  - Patients with intermediate or high pretest probability and low probability with elevated D-dimer need further diagnostic testing.
- Chest x-ray (CXR): Westermark sign (lack of vessels in an area distal to the embolus), Hampton hump (wedge-shaped opacity with base in pleura), Fleischner sign (enlarged pulmonary arteries), pleural effusion, hemidiaphragm elevation
- ECG: right heart strain, nonspecific rhythm abnormalities, S1Q3T3
- CT pulmonary angiography: sensitivity 96–100%, specificity 86–89%; NPV 99.8%. If normal, it excludes PE if low or intermediate clinical probability.
- Ventilation/perfusion scintigraphy (V/Q scan): Use if CT angiography is not available or contraindicated. A high-probability V/Q scan makes the diagnosis of PE; normal V/Q scan excludes PE.
- Pulmonary angiography: gold standard, invasive and technically difficult: 2% morbidity and <0.01 mortality risk
- Echo: assesses RV function and thrombus in transit (associated with >40% mortality)
Magnetic resonance (MR) angiography: lower sensitivity and specificity than CT angiography

CT venography: can be done at the same time as CT angiography; increases diagnostic yield

**ALERT**

If your preclinical probability is intermediate or high and the patient has a low bleeding risk, start treatment while waiting for the diagnostic results.

**Initial Tests (lab, imaging)**

- Labs: CBC: to check for anemia, thrombocytosis, leukocytosis
  - CMP: to check electrolyte abnormalities
  - D-dimer: *used to rule out DVT/PE when clinical suspicion for PE is low to moderate
  - BNP: to rule-out CHF as cause of symptoms (SOB, tachypnea, edema)
  - Troponins: rule out myocardial causes
- Imaging:
  - EKG: Most common finding is sinus tachycardia
  - CXR: If normal with hypoxemia, suspect PE
  - Venous doppler: initial test for DVT; positive venous doppler with SOB and tachypnea can begin treatment for PE

**Follow-Up Tests & Special Considerations**

- Spiral CTA—Test of choice to diagnose PE, performed when clinical suspicion for PE is high
  - *Contraindication: renal failure or contrast allergy
- Lung V/Q scan – Can rule out PE if low clinical suspicion/Wells score

**Diagnostic Procedures/Other**

Pulmonary angiography—definitive test; not used due to risk

**Test Interpretation**

- D-Dimer (performed if Wells criteria for PE is less than or equal to 4)
  - Normal: PE is ruled out.
  - High: Move on to imaging (Spiral CTA).
- Spiral CTA (performed if Wells is greater than 4 or D-Dimer is high). Diagnostic/positive:
  - Treat for PE.
  - Non-diagnostic/contraindicated: Perform V/Q scan, CUS
- V/Q scan, CUS
  - Negative: TEE or MR or pulmonary angiography
  - Positive: Treat for PE.

**TREATMENT**

Treatment is based on risk stratification.

- Low-risk PE – use anticoagulation or IVC filter.
- Submassive PE – anticoagulation + possible INR guided thrombolysis
- Massive PE – anticoagulation + definite INR consult for thrombolysis/embolectomy catheter/surgery
GENERAL MEASURES
Goal to maintain SaO2 at >92%

MEDICATION
- Start LMWH, fondaparinux, UFH, as initial therapy for first 5 to 10 days. VKA can be started the 1st day and must overlap with parenteral treatment for minimum of 5 days, until INR is 2 to 3 for 24 hours.
- Following 5 to 10 days of parenteral therapy, dabigatran or edoxaban is also approved.
- An oral option for initial and long-term treatment is rivaroxaban or apixaban.
- Patients with massive PE with low bleeding risk: Consider systemic thrombolytics if no contraindications.

First Line
- UFH:
  - IV bolus of 80 U/kg or 5,000 U followed by continuous infusion (initially 18 U/kg/hr or 1,300 U/hr) with dose adjustments to maintain aPTT that corresponds to anti-Xa levels of 0.3 to 0.7
  - SC injection: two options:
    - Monitored: 17,500 U or 250 U/kg BID with dose adjustments to maintain an aPTT that corresponds to anti-Xa levels of 0.3 to 0.7 measured 6 hours after a dose
    - Fixed dose: 333 U/kg initial dose, followed by 250 U/kg BID
- LMWH: preferred due to lower risk of major bleeding and heparin-induced thrombocytopenia (HIT)
  - Enoxaparin (Lovenox) 1 mg/kg/dose SC q12h
  - Dalteparin (Fragmin) 200 U/kg SC q24h
  - Fondaparinux (Arixtra) 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100 kg) SC q24h
- Maintenance therapy: warfarin on day 1, if possible; 5 mg/day for 3 days in hospitalized or older patients and at a dose of 10 mg in <60 years of aged patients; adjust dose to maintain an INR of 2 to 3; needs to overlap with UFH, LMWH, or fondaparinux: 5 to 7 days, until 2 consecutive days of therapeutic INR
- Rivaroxaban: 15 mg BID × 3 weeks and then 20 mg once daily to complete treatment. Compared to warfarin, it has less major bleeding side effects while having same efficacy; ok to use in HIT
- Edoxaban: 60 mg once daily (reduced to 30 mg once daily if CrCl 30 to 50 mL/min or body weight <60 kg). Patients require initial treatment with LMWH at least 5 days before starting edoxaban. Compared to warfarin, less bleeding and lower rate of recurrence in PE with RV dysfunction; increased bleeding risk in cancer-associated thrombosis compared to dalteparin
- Apixaban: 10 mg BID for 7 days, then 5 mg once daily; less major bleeding episodes; ok to use in HIT
- Dabigatran: requires initial treatment with LMWH; ok to use in HIT

ALERT
- Contraindications:
  - Active bleeding
  - Heparin: HIT
  - LMWH: HIT, renal failure
– Warfarin: pregnancy
– Rivaroxaban and fondaparinux: renal failure
– Edoxaban: severe kidney or liver failure
– Apixaban: renal impairment and nonvalvular atrial fibrillation
– Dabigatran: severe kidney problems. Use of dronedarone or ketoconazole increases risk.

★ No dose reduction strategy needed to treat acute PE with dabigatran, apixaban, or rivaroxaban

Pregnancy Considerations
★ Warfarin: teratogenic; safe while breastfeeding
★ LMWH: Dalteparin, enoxaparin, and fondaparinux are Category B; heparin is Category C: Use if the benefit outweighs risks.
★ UFH: requires aPTT monitoring; can cause osteoporosis if used for prolonged period
★ Rivaroxaban is Category C.
★ Edoxaban and apixaban: Category B; increase risk of hemorrhage
★ Dabigatran: Category C; only if benefit > risk.

Second Line
Massive PE: thrombolytics if hemodynamic compromise and low bleeding risk, intracranial hemorrhage risk: 0.7–6.4%:
★ Tissue plasminogen activator (tPA) 100 mg infused over 2 hours.
  – Absolute contraindications: Intracranial hemorrhage, intracranial cerebrovascular or malignancy, ischemic stroke <3 months, possible aortic dissection, bleeding diathesis, active bleeding, recent neurosurgery, or major trauma

SURGERY/OTHER PROCEDURES
★ Inferior vena cava (IVC) filter placement if absolute contraindication for anticoagulation or recurrent PE despite adequate anticoagulation treatment
★ Emergency embolectomy can be considered in patients with massive PE with contraindications for thrombolysis.
★ Consider catheter-based interventions if massive PE and thrombolytic contraindications.
★ Consider US-assisted catheter-directed thrombolysis with intermediate risk of death or submassive PE

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
★ In selected, low-risk acute PE population (Pulmonary Embolism Severity Index [PESI] score class I or II), patients could be managed safely and effectively in the outpatient setting with close follow-up.
★ ICU-level care if hemodynamically unstable

ONGOING CARE
Duration of anticoagulation
★ Provoked PE (trigger no longer present): 3 months
★ Unprovoked PE: >3 months; consider long-term or prolonged secondary prophylaxis if bleeding risk is low. HERDOO2 Score provides guidance to determine duration of therapy in women with first unprovoked VTE. Low risk (0 to 1 criteria) can safely stop treatment after 6 months.
Cancer-related PE: LMWH first 3 to 6 months. Consider secondary prophylaxis as long as the patient has active cancer.

Recurrent unprovoked PE: long-term anticoagulation

**FOLLOW-UP RECOMMENDATIONS**

If concomitant DVT, consider 30 to 40 mm Hg knee-high compression stockings.

**Patient Monitoring**

- INR should be checked regularly; target is 2 to 3.
- aPTT needs to be monitored in SC UFH.
- Anti-Xa can be checked in special circumstances if treated with LMWH, including pregnancy, younger patients, renal disease.

**PATIENT EDUCATION**

Patients at risk for forming clots (i.e., sedentary lifestyle, post-surgical patients, hypercoagulable states such as pregnancy or cancer) should be counseled on preventive measures.

**PROGNOSIS**

- Mortality: submassive 6–14%; massive PE 15–60%
- PESI score predicts 30-day mortality. Stratified by risk classes depending on number of risk factors: class I (very low mortality risk; 0–1.6%), class II (low mortality risk; 1.7–3.5%), class III (moderate mortality risk; 3.2–7.1%), class IV (high mortality risk; 4–11.4%), and class V (very high mortality risk; 10–24.5%)
- Any one of the following defines high risk: age >80 years, cancer, chronic cardiopulmonary disease, heart rate 110 beats/min, systolic blood pressure <100 mm Hg, O₂ saturation <90%.
- High early mortality risk: shock or hypotension, + sPESI >1 + RV dysfunction signs
- Intermediate high early mortality risk: no shock or hypotension + sPESI >1 + RV dysfunction signs
- Intermediate low early mortality risk: no shock or hypotension + sPESI >1 + either RV dysfunction by imaging or cardiac laboratory biomarkers
- Low early mortality risk: no shock or hypotension, no sPESI; imaging is optional.
- PE mortality rate is significantly higher in patients with active cancer (up to 47-fold higher). Elevated white blood cell count is a strong predictor of 30-day mortality in cancer population.

**COMPLICATIONS**

- 1 in 25 patients will develop chronic thromboembolic pulmonary hypertension, recurrent DVT, or PE.
- Post-PE syndrome: permanent pulmonary vasculature changes, chronic dyspnea, reduced exercise capacity
- Younger age, previous PE, and larger perfusion defect associated with increased risk of chronic thromboembolic pulmonary.

**REFERENCES**

CODES

ICD10
- I26.99 Other pulmonary embolism without acute cor pulmonale
- I27.82 Chronic pulmonary embolism

CLINICAL PEARLS
- Use Wells criteria; obtain D-dimer for low and intermediate risk; spiral CT angiography for high risk.
PULMONARY FIBROSIS
Sheshadrie Saha, MD  Avignat S. Patel, MD

BASICS

DESCRIPTION
- Pulmonary fibrosis (PF) is a part of interstitial lung diseases (ILDs) that is a family of >200 different lung diseases, which are characterized by inflammation, cellular proliferation, and/or fibrosis within lung interstitium and bronchial walls. If no cause identified, ILD is called idiopathic interstitial pneumonia.
- The most common idiopathic interstitial pneumonia is idiopathic PF (IPF).
- IPF is defined as a specific form of chronic fibrosing interstitial pneumonia limited to the lung and associated with the histologic and/or radiologic appearance of usual interstitial pneumonia (UIP) when other causes have been excluded.

EPIDEMIOLOGY
- Most common ILD prevalent worldwide accounting for 25–30% of all ILD
- Most common in men >60 years of age

Incidence
Higher in North America and Europe (3 to 9 cases per 100,000 person-years) than in South America and East Asia (fewer than 4 cases per 100,000 person-years)

Prevalence
Exact prevalence is unknown. In the United States, the prevalence of IPF has been reported to range from 10 to 60 cases per 100,000.

ETIOLOGY AND PATHOPHYSIOLOGY
- Exact inciting factors unknown.
- A favored model for the pathogenesis of IPF is that recurrent, subclinical epithelial damage with accelerated epithelial cell senescence leads to abnormal repair of the alveolus and deposition of interstitial fibrosis by myofibroblasts.
- Causes of nonidiopathic PF include occupational and environmental exposures, drugs, and connective tissue diseases.
- IPF pattern on histopathology is UIP, which appears to be a distinct pathophysiologic entity characterized by minimal inflammation and chronic fibroproliferation due to abnormal parenchymal wound healing.

Genetics
- The role of host genetic factors and their interactions with environmental factors leading to IPF is unknown.
- Mutations in genes involved in maintenance of telomere length are associated with increased risk of IPF.
- An SNP in the MUC5B promoter leads to gene over expression and is associated with increased risk of IPF. However, the mechanism linking MUC5B and IPF is not clear.

RISK FACTORS
• Family history of IPF
• Smoking—most significant association
• GERD, OSA
• Occupational and environmental exposures: wood (pine), metal dusts (lead, brass, steel), farming, raising birds, hairdressing, stone cutting, exposure to livestock, vegetable and animal dust, and air pollution

GENERAL PREVENTION
It is general avoidance of above noted risk factors.

COMMONLY ASSOCIATED CONDITIONS
• Pulmonary hypertension: 30–80% of patients with IPF
• GERD
• Nonidiopathic PF may be related to connective tissue diseases (RA and scleroderma).

DIAGNOSIS

HISTORY
• Very insidious and slow onset
• Exertional breathlessness and nonproductive cough
• Constitutional symptoms are uncommon but can present with weight loss, fever, fatigue, myalgias, and arthralgias.
• Obtain history of exposure to dampness, mold, or birds in the home or workplace and history suggestive of other causes of ILD.

PHYSICAL EXAM
• Bibasilar fine, late inspiratory crackles: velcro crackles
• Clubbing in late stages, cyanosis (rare)
• Findings of pulmonary hypertension and right-sided heart failure
• Pneumothorax and pneumomediastinum (rare)
• Look for signs and symptoms of autoimmune conditions and connective tissue disorders.

DIFFERENTIAL DIAGNOSIS
• Other ILDs such as chronic hypersensitivity pneumonitis, nonspecific interstitial pneumonia, occupational lung disease, connective tissue disease-ILD (CTD-ILD)
• See below for histologic differential diagnosis of UIP.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Blood tests: Most labs are normal.
• Chest radiograph:
  – Reduced lung volumes and reticular opacities mostly at lung bases
  – Coarse reticular pattern and honeycombed cysts in advanced stages
• Pleural abnormalities (such as pleural plaques, effusions) are uncommon. Presence should suggest alternate diagnosis.

Follow-Up Tests & Special Considerations
● Chest CT scan:
  – Once diagnosis of IPF is suspected, high-resolution CT (HRCT) scan of chest is needed. It should include inspiratory and expiratory images with thin <1.25 mm slices, and prone position should be included if subtle subpleural basal changes are present.
  – Four distinct patterns are noted on HRCT: UIP, probable UIP, indeterminate, and alternative diagnosis.
  – UIP diagnosis requires bilateral reticulation that is primarily peripheral and in the lower lobes AND honeycombing. If no secondary cause is identified, and radiologic UIP pattern is seen on HRCT, this is diagnostic of IPF without need for surgical lung biopsy.
  – Similar changes (as described above) in the absence of honeycombing would be categorized as probable UIP.
  – Atypical features on HRCT include upper- or mid-lung predominance, predominant consolidation, ground-glass opacities, and diffuse nodules or cysts; these increase the likelihood of an ILD other than IPF.
● Serologic testing for connective tissue diseases: should be obtained when IPF is being considered to exclude nonidiopathic causes. ANA; RF; anti–CCP antibodies; Scl-70, Ro, La, U1-RNP, and Jo-1; creatine kinase; and myoglobin and antisynthetase antibodies.
● Echocardiogram to assess cardiac function, right ventricular function, and pulmonary hypertension

**Diagnostic Procedures/Other**

● Pulmonary function testing (PFT):
  – PFTs in all patients undergoing evaluation and treatment of IPF or any other ILD
  – Findings include:
    o Decreased diffusion capacity for carbon monoxide (DLCO)
    o Decreased lung volumes (TLC, RV, FRC)
    o Decreased expiratory flow rates (FVC and FEV1): may be decreased because of the reduction in lung volume, but the FEV1/FVC ratio is maintained.
● Exercise stress testing shows tachypnea, with rapid shallow breathing with increase in their minute ventilation.
● ABG: Resting ABG shows hypoxemia and respiratory alkalosis.
● 6-minute walk distance (6MWD)
  – 6MWD has high correlation with DLCO and mortality.
● Sleep study:
  – Sleep disturbances with reduced rapid eye movement sleep, lighter and more fragmented sleep, and hypoxemia during rapid eye movement sleep.
  – Tachypnea persists during sleep.
● Bronchoscopy:
  – Bronchoalveolar lavage (BAL):
    o Can be helpful in excluding other diagnoses like infection, malignancy etc.
    o ATS/ERS does not recommend routine use of BAL if HRCT is diagnostic of UIP.
  – Bronchoscopic transbronchial biopsy:
    o It is not recommended for diagnosis of IPF as sensitivity and specificity is unknown and it is unknown from where biopsy should be taken as disease is heterogeneous.
    o It may help to exclude other possible etiologies of ILD.
    o Transbronchial lung cryobiopsy has been increasingly advocated as a replacement for thoracoscopic biopsy. Data is limited at this point.
Surgical lung biopsy:
- Gold standard for diagnosis of ILDs
- When the combination of clinical and imaging data is not diagnostic, a thoracoscopic lung biopsy can be considered if the results are expected to influence therapy.
- Biopsy samples should be taken from multiple lobes and avoid sampling the most severely affected areas as they will show nondiagnostic fibrosis.
- Procedure should not be performed in high-risk patients, including:
  - High oxygen requirements (>2L/min)
  - Significant pulmonary hypertension
  - Rapid disease progression
  - Severely reduced FVC or DLCO
- Several studies have compared video-assisted thoracoscopic biopsy (VATS) with open thoracotomy biopsy and noted that diagnostic yield is similar but morbidity less with VATS.

**Test Interpretation**

- Histopathology
  - Gross appearance of the lungs: distinctive nodular pleural surface.
  - The histopathologic pattern in IPF is UIP.
    - UIP pattern requires dense fibrosis with architectural distortion, subpleural, and basal distribution, heterogeneous pattern (spatial and temporal), fibroblastic foci, and microscopic honeycomb changes plus absence of features suggestive of alternate diagnosis.
    - Differential diagnosis of UIP pattern in histology includes IPF, connective tissue diseases like RA and scleroderma, chronic hypersensitivity pneumonitis, asbestosis, chronic aspiration pneumonia, chronic radiation pneumonitis, Hermansky-Pudlak syndrome and neurofibromatosis.

- Diagnostic Strategies:
  - As per ATS/ERS statement of IPF in 2018, diagnosis of IPF requires (1):
    - Exclusion of other known causes of ILD and either of the following:
      - The presence of UIP pattern on HRCT
      - Specific combinations of HRCT patterns and histopathology patterns in patients subjected to lung tissue sampling
    - UIP pattern on HRCT would be diagnostic with all histology patterns except alternate diagnosis findings.
    - UIP pattern on histology would be diagnostic with all HRCT patterns except alternate diagnosis findings.
    - Per ATS/ERS, for patients suspected of having IPF, a multidisciplinary team (pulmonologists, radiologists, pathologists, rheumatologists) is recommended for diagnostic decision-making.

**TREATMENT**

**GENERAL MEASURES**
- Smoking cessation
- Pulmonary rehabilitation
Referral to a transplant center

Supplemental oxygen:
- Clinical practice guidelines strongly recommend supplemental oxygen.
- Goal oxyhemoglobin saturation >88%.
- The oxygen prescription should be informed by 6-minute walk tests or treadmill testing of oxygen saturation as well as by nocturnal oximetry or polysomnography when indicated.

MEDICATION
- IPF is a progressive and fatal disorder without spontaneous remission.
- Median survival after diagnosis is 3.8 years.
- Any therapy of IPF, regardless of the agent used, requires at least 1 year before its effectiveness can be assessed.
- During the past 5 years, notable advances have been made in pharmacotherapeutic approaches to IPF.
- Two medications, nintedanib and pirfenidone, have been shown to be safe and effective in the treatment of IPF; both are recommended for use in patients with IPF.
  - In placebo-controlled, randomized trials, each drug has been shown to slow the rate of FVC decline by approximately 50% over the course of 1 year.
  - Both have shown some efficacy in reducing severe respiratory events, such as acute exacerbations and hospitalization for respiratory events.
  - Pooled data and meta-analyses suggest that these agents may reduce mortality.
  - The cost of each medication is estimated to exceed $100,000 annually.

First Line
- Nintedanib:
  - Mechanism of action: tyrosine kinase inhibitor that targets growth factor pathways including vascular endothelial growth factor receptors, fibroblast growth factor receptors, and platelet-derived growth factor receptors.
  - Most common side effect is diarrhea. It is also associated with a small increase in the risk of bleeding and should be used cautiously, if at all, in patients on full dose anticoagulation.
  - Liver function should be followed as liver toxicity has been reported.
- Pirfenidone:
  - Mechanism of action: anti-inflammatory and antifibrotic effects, including inhibition of collagen synthesis, down regulation of TGF-β and tumor necrosis factor-α, and reduction in fibroblast proliferation.
  - Common side effects: anorexia, nausea, and vomiting, photosensitive rash, abnormal liver function
  - It is difficult to recommend one agent over the other because there have been no head-to-head comparisons and efficacy is similar. Recent data on treatment that combines these agents suggest clinically significant gastrointestinal side effects.
- Reflux management:
  - Treatment of coexistent GERD because it is very common and some data suggested worsening of IPF with ongoing reflux. However, there is no data from clinical trials to support this recommendation.

Second Line
- No second-line agents available to specifically treat IPF.
Treatment guidelines for IPF by ATS/ERS include:
- Strong recommendations against use of:
  - Anticoagulation (warfarin)
  - Combination prednisone + azathioprine + N-acetylcysteine (NAC)
  - Selective endothelin receptor antagonist (ambrisentan)
  - Imatinib, a tyrosine kinase inhibitor with one target
- Conditional recommendations against:
  - Dual endothelin receptor antagonists (macitentan, bosentan)
  - Phosphodiesterase-5 inhibitor (sildenafil)
  - NAC monotherapy

ISSUES FOR REFERRAL
- Referral to pulmonologist for diagnosis and management
- Thoracic surgeon referral is indicated if patient cannot be diagnosed by ATS clinical and radiographic criteria.
- Referral to lung transplant center is indicated early on for patients showing progressive worsening of the disease.

ADDITIONAL THERAPIES
Several investigational therapies are being studied in different randomized controlled trials.

SURGERY/OTHER PROCEDURES
Lung transplant:
- Can prolong survival and improve quality of life for highly selected candidates
- Only a minority of patients with IPF receive lung transplants
- Only 66% of lung transplant recipients survive for more than 3 years after transplant and only 53% survive for more than 5 years
- Common complication include primary graft dysfunction, acute and chronic allograft rejection, CMV and other infections, and cancer.

COMPLEMENTARY & ALTERNATIVE MEDICINE
No proven benefit of any of the complementary and alternative medications. Patient should be vaccinated for influenza and pneumonia.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Acute exacerbation of IPF should be admitted to the hospital for management with corticosteroids.
- Mechanical ventilation carries a poor prognosis and should be avoided if possible.
- Palliative care consult is appropriate for all patients diagnosed with IPF.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Pulmonary clinic and, if possible, at an ILD clinic.
- Monitoring with serial HRCT and PFT along with 6MWD and exercise oximetry
- If on treatment with any of the newly approved medications, monitor LFTs.
PROGNOSIS
IPF carries a poor prognosis with a median survival of 3.8 years among adults 65 years of age or older in the United States.

COMPLICATIONS
- Acute exacerbation of IPF
  - 10–20% per patient per year
  - It is characterized by worsened hypoxemic respiratory failure, with bilateral ground-glass opacities, consolidation, or both on HRCT imaging that are not fully explained by volume overload or infection.
  - Triggers: infection, aspiration, or drug toxicity or idiopathic
  - Treatment: Available guidelines make weak recommendations for the use of glucocorticoids and do not recommend the use of mechanical ventilation. Consider palliative care referral.
- Increased risk for VTE, lung cancer, and pulmonary hypertension
  - Management of pulmonary hypertension in the outpatient setting should consist solely of supplemental oxygen, without pulmonary vasodilator therapy. Until further data is available, targeted therapies approved for pulmonary arterial hypertension should be avoided in patients with IPF unless they are enrolled in a clinical trial investigating such therapies.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- J84.10 Pulmonary fibrosis, unspecified
- J84.112 Idiopathic pulmonary fibrosis

CLINICAL PEARLS
- IPF is most common idiopathic ILD and frequently misdiagnosed and mistreated.
- High Resolution CT scan is the cornerstone for diagnosis.
- Until recently available two newer drugs, no other therapy has proven effective in management.
- Oxygen supplementation, pulmonary rehab, anti-reflux treatment, vaccinations against pneumonia and influenza should be considered in all patients.
Referral to pulmonary clinic, ILD clinic, and lung transplant center should be considered very early in course.
PYELONEPHRITIS
Katelin M. Lisenby, PharmD, BCPS • Catherine Scarbrough, MD, MSc, FAAFP • Dana G. Carroll, PharmD, BCPS, CDE, BCGP

BASICS

DESCRIPTION
- A syndrome caused by infection of the renal parenchyma and/or renal pelvis, often producing localized flank/back pain combined with systemic symptoms, such as fever, chills, and nausea; wide spectrum from mild illness to septic shock
- Chronic pyelonephritis is the result of progressive inflammation of the renal interstitium and tubules, due to recurrent infection, vesicoureteral reflux, or both.
- Pyelonephritis is considered uncomplicated if the infection is caused by a typical pathogen in an immunocompetent patient with normal urinary tract anatomy and renal function.
- System(s) affected: renal; urologic
- Synonym: acute upper urinary tract infection (UTI)

Geriatric Considerations
- May present as altered mental status; absence of fever is common in this age group.
- Elderly patients with diabetes and pyelonephritis are at higher risk of bacteremia, longer hospitalization, and mortality.
- The high prevalence of asymptomatic bacteriuria in the elderly makes the use of urine dipstick less reliable for diagnosing UTI in this population.

Pregnancy Considerations
- Most common medical complication requiring hospitalization. Pregnant women with asymptomatic bacteriuria (ABU) have 20–30% risk to develop acute pyelonephritis if ABU is not treated.
- Affects 1–2% of all pregnancies. Morbidity does not differ between trimesters.
- Urine culture for test of cure 1 to 2 weeks after therapy.

Pediatric Considerations
- UTI is present in ~5% of patients age 2 months to 2 years with fever and no apparent source on history and physical exam.
- Treatment (PO or IV; inpatient or outpatient) should be based on the clinical situation and patient toxicity.

EPIDEMIOLOGY

Incidence
Community-acquired acute pyelonephritis: 3–4 cases per 10,000 males; 15–17 cases per 10,000 females. 28 cases per 10,000 women ages 18–49 years.

Prevalence
Adult cases: 250,000/year, with 200,000 hospitalizations

ETIOLOGY AND PATHOPHYSIOLOGY
Escherichia coli (>80%)  
Other gram-negative pathogens: Proteus, Klebsiella, Serratia, Clostridium, Pseudomonas, and Enterobacter spp.  
Enterococcus spp.  
Staphylococcus: Staphylococcus epidermidis, Staphylococcus saprophyticus (number 2 cause in young women), and Staphylococcus aureus  
Candida spp.  

RISK FACTORS  
- Underlying abnormalities in the anatomy of the urinary tract  
- Indwelling catheter/recent urinary tract instrumentation  
- Nephrolithiasis  
- Immunocompromised, including diabetes  
- Elderly, institutionalized patients (particularly women)  
- Prostatic enlargement  
- Childhood UTI  
- Acute pyelonephritis within the prior year  
- Frequent recent sexual intercourse; spermicide use; new sex partner within the prior year  
- Stress incontinence in the previous 30 days  
- Pregnancy  
- Hospital-acquired infection  
- Symptoms >7 days at time of presentation  

COMMONLY ASSOCIATED CONDITIONS  
- Indwelling catheters  
- Renal calculi  
- Benign prostatic hyperplasia  

DIAGNOSIS  

HISTORY  
- In adults  
  - Fever; flank pain  
  - Nausea ± vomiting  
  - Malaise, anorexia  
  - Myalgia  
  - Dysuria, urinary frequency, urgency  
  - Suprapubic discomfort  
  - Mental status changes (elderly)  
- In infants and children  
  - Fever  
  - Irritability and poor feeding  
  - GI symptoms  

PHYSICAL EXAM  
- In adults  
  - Fever: ≥38°C (100.4°F)
– Costovertebral angle tenderness
– Presentation ranges from no physical findings to septic shock.
– Mental status changes common in the elderly
– A pelvic exam may be necessary in female patients to exclude pelvic inflammatory disease.

• In infants and children
  – Lethargy
  – Fever
  – Poor skin perfusion
  – Inadequate weight gain/weight loss
  – Jaundice to gray skin color

DIFFERENTIAL DIAGNOSIS
• Obstructive uropathy
• Acute bacterial pneumonia (lower lobe)
• Cholecystitis
• Acute pancreatitis
• Appendicitis
• Perforated viscus; aortic dissection
• Pelvic inflammatory disease; ectopic pregnancy
• Kidney stone
• Diverticulitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Urinalysis: pyuria (>5 wbc/hpf) ± leukocyte casts, hematuria, nitrites (sensitivity 35–85%; specificity 92–100%), and mild proteinuria
• Urine leukocyte esterase positive (sensitivity 74–96%; specificity 94–98%)
• Urine Gram stain; urine culture (>100,000 colony forming units/mL or >100 colony forming units/mL + symptoms) and sensitivities
• Complete blood count, blood urea nitrogen, creatinine, glomerular filtration rate (GFR), and pregnancy test (if indicated)
• C-reactive protein levels have been shown to correlate with prolonged hospitalization and recurrence; serum albumin <3.3 g/dL also associated with risk for hospital admission
• Imaging not necessary in routine cases
• Pediatrics: Guidelines recommend renal/bladder US (not voiding cystourethrogram) after first UTI.

Follow-Up Tests & Special Considerations
• Catheterization/suprapubic aspirate to obtain samples from non–toilet-trained children
• Catheterization may be necessary for some geriatric patients.
• Blood culture(s): if hospitalized, diagnosis uncertain, suspected hematogenous source or immunosuppression
• Recent antibiotic use may alter lab results.
• If patient’s condition does not improve within 72 hours, if obstruction/anatomic abnormality suspected, in patients with immunosuppression or multiple comorbidities, and/or if certain lab abnormalities are present (urine pH >7, GFR <40, 50% decline in renal function), consider:
  – CT scan of abdomen and pelvis ± contrast Contrast-enhanced computed tomography
(CECT) is typically the image of choice for children and adults with acute pyelonephritis to identify changes in renal perfusion, parenchymal change, and perinephric change.
- US of kidneys, ureter, bladder is not as sensitive as CT, but is cheaper and more readily available.
- Cystoscopy with ureteral catheterization

**Test Interpretation**
- Acute: abscess formation with neutrophil response
- Chronic: fibrosis with reduction in renal tissue

**TREATMENT**
- ≤7 days of treatment is equivalent to longer regimens in adults (including those with bacteremia) without urogenital abnormalities (1,2)[A].
- IV antibiotics for inpatients who are toxic appearing or unable to tolerate oral antibiotics

**GENERAL MEASURES**
- Broad-spectrum antibiotics initially based on severity of illness, health status, and risk factors for resistant pathogens; tailor to culture and sensitivity results.
  - Risk factors for a multidrug-resistant (MDR) pathogens/infections if present within last three months:
    - History of urinary MDR pathogen
    - Inpatient stay at a health care facility (hospital, nursing home, etc.)
    - Use of fluoroquinolone, trimethoprim-sulfamethoxazole (TMP-SMX), or broad-spectrum β-lactam
    - Travel to geographical regions with significant incidence of MDR pathogens (e.g., India, Middle East, Central America)
- Analgesics and antipyretics
- Consider urinary analgesics (e.g., phenazopyridine 200 mg q8h) for dysuria.

**MEDICATION**
- For empiric oral therapy, a fluoroquinolone is recommended. Should fluoroquinolone resistance exceed 10% or the patient has nausea/vomiting, a single initial IV dose of a long-acting antibiotic such as ceftriaxone 1 g is recommended.
- For parenteral therapy, fluoroquinolone, aminoglycoside with or without ampicillin, an extended-spectrum cephalosporin with or without a β-lactamase inhibitor, an extended-spectrum penicillin with or without an aminoglycoside, or a carbapenem are recommended.
- Contraindications:
  - Known drug allergy
  - Fluoroquinolones are not recommended in children, adolescents, and pregnant women unless other alternatives are not available.
  - Nitrofurantoin does not achieve reliable tissue levels for treatment of pyelonephritis.
- Precautions:
  - Most antibiotics require adjustments in dosage for patients with renal insufficiency.
  - Monitor aminoglycoside levels and renal function.
  - If Enterococcus is suspected based on Gram stain, ampicillin ± gentamicin or piperacillin-tazobactam are reasonable empiric choices; unless patient is penicillin allergic, then use
vancomycin. If outpatient, add amoxicillin to fluoroquinolone, pending culture results and sensitivity. Do not use a 3rd-generation cephalosporin for suspected/proven enterococcal infections.

- >20% E. coli strains are resistant to ampicillin and trimethoprim-sulfamethoxazole (TMP-SMX) in community-acquired infections.
- Extended-spectrum β-lactamase (ESBL)-producing strains should be treated with a carbapenem ± β-lactamase inhibitor or ceftolozane-tazobactam or plazomicin (3)[A],(4)[A].

**First Line**

- Adults
  - Oral (initial outpatient treatment)
    o Ciprofloxacin: 500 mg q12h for 7 days
    o Ciprofloxacin XR: 1,000 mg/day for 7 days
    o Levofloxacin: 750 mg/day for 5 days
    o TMP-SMX (160/800 mg): 1 tab q12h for 14 days provided uropathogen known to be susceptible ± ceftriaxone 1 g initial IM/IV dose
  - IV (initial inpatient treatment for patients with no risk factors for MDR organisms)
    o Ciprofloxacin: 400 mg q12h
    o Levofloxacin: 750 mg/day
    o Cefotaxime: 1 g q8–12h up to 2 g q4h
    o Ceftriaxone: 1 to 2 g/day
    o Cefepime: 1 to 2 g q12h
    o Gentamicin: 5 to 7 mg/kg body weight daily
    o Piperacillin-tazobactam: 3.375 g q6–8h
    o Ampicillin: 2 g q6h ± gentamicin for Enterococcus
  - IV (initial inpatient treatment for patients with at least one risk factor for MDR organisms)
    o Antipseudomonal carbapenem
      ■ Meropenem: 1 g q8h
      ■ Imipenem: 500 mg q6h
      ■ Doripenem: 500 mg q8h
    - Add vancomycin for methicillin-resistant Staphylococcus aureus (MRSA) or daptomycin or linezolid for vancomycin-resistant Enterococcus (VRE).
    - Severe illness: IV therapy until afebrile for 24 to 48 hours and tolerating PO intake. Switch to oral agents to complete up to a 2-week course.

- Pediatric
  - Oral: cefdinir: 14 mg/kg/day for 10 to 14 days; ceftibuten 9 mg/kg/day for 10 to 14 days; cefixime 8 mg/kg/day for 10 to 14 days
  - IV (General indication for IV therapy is age <2 months or clinical concern in other ages.)
    o Ceftriaxone: 75 mg/kg/day (IM use acceptable in outpatient setting)
    o Cefotaxime: 150 mg/kg/day divided in 3 to 4 doses
    o Ampicillin: 100 mg/kg/day divided in 4 doses + gentamicin 7.5 mg/kg/day divided in 3 doses

**Second Line**

Adults

- Oral
  - Oral β-lactams should be used with caution due to inferior efficacy and higher relapse rates;
if used, provide an initial IV dose of ceftriaxone or a consolidated 24-hour dose of an aminoglycoside; longer courses of therapy (10 to 14 days) recommended
- Cefpodoxime (Proxetil): 200 mg q12h
- Amoxicillin-clavulanate: 875/125 mg q12h or 500/125 mg q8h

**IV**
- Ticarcillin-clavulanate: 3.1 g q4–6h
- Targeted therapy for MDR organisms
  - Ertapenem: 1 g q24h
  - Ceftazidime-avibactam: 2.5 g q8h
  - Ceftolozane-tazobactam: 1.5 g q8h
  - Meropenem-vaborbactam: 4 g q8h (3)[A]
  - Plazomicin: 15 mg/kg/day (4)[A]

**Pediatric Considerations**
- Treat children <2 years of age and children with febrile or recurrent UTI for 10 to 14 days.
- Initial empiric antibiotic choice should cover *E. coli*. Add ampicillin if Enterococcus is suspected.
  - Oral antibiotics (ceftibuten, cefixime, and amoxicillin/clavulanic acid) may be used alone, or
  - IV antibiotics (single daily dosing if an aminoglycoside is chosen) for 2 to 4 days, followed by oral antibiotics for a total of 10 to 14 days
- Complete outpatient antibiotic course in entirety.

**ISSUES FOR REFERRAL**
- Acute pyelonephritis unresponsive to therapy
- Chronic pyelonephritis
- Abnormal urogenital anatomy

**SURGERY/OTHER PROCEDURES**
Perinephric abscess may require surgical drainage.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient therapy for severe illness (e.g., high fevers, severe pain, marked debility, intractable vomiting, inability to tolerate oral intake, possible sepsis), risk factors for complicated pyelonephritis, pregnancy, or extremes of age
- Outpatient therapy if mild to moderate illness (not pregnant, no nausea/vomiting; fever and pain not severe), uncomplicated course, and tolerating oral intake. Many patients can be treated as outpatients.
- IV fluids as indicated for dehydration or renal calculi. Blood cultures generally recommended for patients admitted with pyelonephritis.
- Discharge on oral agent after patient is afebrile 24 to 48 hours to complete up to 2 weeks of therapy.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Women: routine follow-up cultures not recommended unless symptoms recur after 2 weeks
and then urologic evaluation is necessary

- Men, children, adolescents, patients with recurrent infections, patients with risk factors: Repeat cultures 1 to 2 weeks after completing therapy; urologic evaluation after first episode of pyelonephritis and with recurrences

**Patient Monitoring**

- If no response within 48 hours (5% of patients): Reevaluate and review cultures, CT scan, or US to review anatomy; adjust therapy as needed; urologic or infectious disease consult. The two most common causes of failure to respond are a resistant organism and nephrolithiasis.
- Work with parents to monitor response in children.

**DIET**

Encourage fluid intake.

**PROGNOSIS**

95% of treated patients respond within 48 hours.

**COMPLICATIONS**

- Renal abscess; perinephric abscess
- Metastatic infection: skeletal system, endocardium, eye, meningitis with subsequent seizures
- Septic shock and death
- Acute/chronic renal failure

**REFERENCES**

**CODES**

**ICD10**

- **N12** Tubulo-interstitial nephritis, not spcf as acute or chronic
- **N10** Acute tubulo-interstitial nephritis
- **N11.9** Chronic tubulo-interstitial nephritis, unspecified
CLINICAL PEARLS

- Pyelonephritis can present with isolated confusion or mental status changes (no fever) in the elderly.
- The most common causes of poor response to treatment are antibiotic resistance and coexisting nephrolithiasis.
- Fluoroquinolones are generally the initial antibiotic of choice for pyelonephritis. Oral β-lactams are less effective. Parental β-lactams may be used in cases of complicated UTIs.
PYLORIC STENOSIS
Jennifer M. Cornwell, DO

BASICS

DESCRIPTION
- Progressive narrowing of the pyloric canal, occurring in infancy
- Synonym(s): infantile hypertrophic pyloric stenosis (IHPS)

EPIDEMIOLOGY
- Onset almost always between 2 and 12 weeks of age
- Considered the most common condition requiring surgical intervention in the 1st year of life
- A recent decline in incidence has been reported in a number of countries.
- Predominant sex: male > female (4 to 5:1)

Incidence
In Caucasian population, 2 to 5:1,000 babies; less common in African American and Asian populations

Prevalence
National prevalence level is 1 to 2:1,000 infants, ranging from 0.5 to 4.21:1,000 live births.

ETIOLOGY AND PATHOPHYSIOLOGY
- Abnormal relaxation of the pyloric muscles leads to hypertrophy.
- Redundant mucosa fills the pyloric canal.
- Gastric outflow is obstructed, leading to gastric distension and vomiting.
- The exact cause remains unknown, but multiple genetic and environmental factors have been implicated.
- Increased vasoactive intestinal peptide in breast milk may mediate pyloric relaxation and increase gastric emptying, protecting from pyloric stenosis
- Formula feeding may cause higher serum levels associated with pylorospasm, increasing rates of pyloric stenosis (1)[C].

Genetics
Recent studies have identified linkage to chromosomes 3, 5, 11, and 19.

RISK FACTORS
- 5 times increased risk with affected first-degree relative
- Strong familial aggregation and >80% heritability
- Multiple gestation
  - 200-fold increased risk if monozygotic twin affected
  - 20-fold increased risk if dizygotic twin affected
- Perinatal risk factors include C-section, preterm infant, and first born
- Breastfeeding is protective whereas formula feeding increases risk

COMMONLY ASSOCIATED CONDITIONS
Associated anomalies present in ~4–7% of infants with pyloric stenosis
• Hiatal and inguinal hernias (most common)
• Other anomalies include the following:
  – Congenital heart disease
  – Esophageal atresia
  – Tracheoesophageal fistula
  – Renal abnormalities
  – Turner syndrome and trisomy 18
  – Cornelia de Lange syndrome
  – Smith-Lemli-Opitz syndrome

**DIAGNOSIS**

**HISTORY**
• Nonbilious projectile vomiting after feeding, increasing in frequency and severity
• Emesis may become blood-tinged from gastric irritation.
• Hunger due to inadequate nutrition
• Excessive crying
• Decrease in bowel movements
• Weight loss

**PHYSICAL EXAM**
• Firm, mobile (“olive-like”) mass palpable in the right upper quadrant (historically 70–90% of the time)
• However, this finding has decreased in occurrence to about 13% due to earlier diagnosis with ultrasound (US) (1)[C].
• Epigastric distention
• Visible gastric peristalsis after feeding
• Late signs: dehydration, weight loss
• Rarely, jaundice when starvation leads to decreased glucuronyl transferase activity resulting in indirect hyperbilirubinemia.

**DIFFERENTIAL DIAGNOSIS**
• Inexperienced or inappropriate feeding
• Gastroesophageal reflux disease
• Gastritis
• Congenital adrenal hyperplasia, salt-wasting
• Pylorospasm
• Gastric volvulus
• Antral or gastric web

**DIAGNOSTIC TESTS & INTERPRETATION**
Metabolic disturbances are late findings and are uncommon in present era of early diagnosis and intervention.
• If prolonged vomiting, check electrolytes for the following:
  – Hypokalemia
  – Hypochloremia
  – Metabolic alkalosis
- Elevated unconjugated bilirubin level (rare)
- Paradoxical aciduria: The kidney tubules excrete hydrogen to preserve potassium in face of hypokalemic alkalosis.

**Initial Tests (lab, imaging)**
- Abdominal US is the study of choice.
  - US shows thickened and elongated pyloric muscle and redundant mucosa.
  - Pathologic limits are 3-mm pyloric muscle thickness, 15-mm pyloric length, 11-mm pyloric diameter, and 12-mL pyloric volume with muscle thickness being the key factor. While these measurements remain diagnostic, they may exclude younger, smaller infants who can be clinically diagnosed (2)[B].
- Upper gastrointestinal (GI) series reveals strong gastric contractions; elongated, narrow pyloric canal (string sign); and parallel lines of barium in the narrow channel (double-tract sign or railroad track sign).

**Test Interpretation**
Concentric hypertrophy of pyloric muscle

---

**TREATMENT**

**MEDICATION**

**First Line**
- Medical treatment with oral or IV atropine is an alternative to surgical treatment for IHPS (3).
- Oral atropine: no reported adverse effects; initial dose of 0.05 mg/kg/day and increased to max of 0.1 mg/kg/day
- IV atropine: initial dose of 0.1 mg/kg/day and increased by 0.01 mg/kg/day until vomiting ceases then change to oral atropine at twice the effective IV dose
- Recommended for use in patients with major concurrent disease
- Takes 5–15 months for pyloric muscle to normalize on medical therapy, although vomiting will usually cease within 7 days

**SURGERY/OTHER PROCEDURES**
- Ramstedt pyloromyotomy is curative. The entire length of hypertrophied muscle is divided, with preservation of the underlying mucosa.
- Surgical approaches include traditional right upper quadrant transverse incision, more contemporary circumumbilical incision, and laparoscopic techniques.
- Recent reviews have concluded that the laparoscopic approach results in less postoperative pain, shorter hospital stays, shorter postoperative recovery, lower complication rates, and improved cosmesis, and can be performed with no increase in operative time or complications (4)[A],(5)[B].
- Recommended in patients with severe dehydration and hematemesis (3)

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Prompt treatment to avoid dehydration and malnutrition
- Correct acid–base and electrolyte disturbances. Surgery should be delayed until metabolic derangements are corrected.
Patients need pre- and postoperative apnea monitoring due to a tendency to compensate with respiratory acidosis (apnea) for their metabolic alkalosis.

IV fluids to correct dehydration and metabolic abnormalities. For optimal resuscitation in infants, use D5 1/2NS with 20 mEq of KCl (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Routine pediatric health maintenance
- Postoperative monitoring, including monitoring for pain, emesis, apnea
- If significant emesis present after 1 to 2 weeks, then upper GI studies needed to rule out incomplete pyloromyotomy or duodenal leak (1)[C]

**DIET**
- No preoperative feeding
- Adlib feedings are recommended after pyloromyotomy as they decrease length of stay.
- Timing of first feed is not significant, but early feeding is associated with increased potential for emesis without impacting length of stay (6)[A].

**PROGNOSIS**
Surgery is curative.

**COMPPLICATIONS**
- No long-term morbidity
- Incomplete pyloromyotomy
- Mucosal perforation
- Wound infections
- Delayed feeding due to postoperative vomiting
- Serosal tear
- Subcutaneous emphysema
- 4.6–12% complication rate (2)[C]

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
Q40.0 Congenital hypertrophic pyloric stenosis

CLINICAL PEARLS

- Pyloric stenosis is the most common condition requiring surgical intervention in the 1st year of life.
- The condition classically presents between 1 and 5 months of life, with projectile vomiting
after feeds and a firm, mobile mass in the right upper quadrant.

- Abdominal US is the study of choice.
- Surgery (laparoscopic Ramstedt pyloromyotomy is the preferred method) is curative, but conservative medical management with atropine can be safe and effective as well.
RABIES
Ashley Twyman, MD ● Laura B. Bishop, MD

BASICS

DESCRIPTION
- A rapidly progressive central nervous system (CNS) infection caused by a ribonucleic acid (RNA) rhabdovirus affecting mammals, including humans
- May present with either encephalitic or paralytic symptoms
- Generally considered to be 100% fatal once symptoms present
- Vaccine-preventable
- System(s) affected: Central nervous system
- Synonym(s): Hydrophobia (inability to swallow water)

EPIDEMIOLOGY
- Present on all continents except Australia and Antarctica
- >95% of human deaths related to rabies occur in Asia and Africa.
- Bats are the most common reservoir in the United States.
- Dogs are the most common reservoir worldwide.

Incidence
- Estimated 55,000 deaths worldwide per year
- Typically only 1 to 3 cases per year in the United States: 1/3 of those exposures occur outside of the United States
- Predominant age: 40% of people worldwide bitten by suspected rabid animals are children <20 years of age.
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY
- Family Rhabdoviridae; genus Lyssavirus: bullet-shaped, enveloped, neurotropic virus
- Transmission occurs mainly via bites from infected animals or when saliva from an infected animal comes in contact with an open wound or mucous membrane.
  - However, 60% of human cases of bat-variant virus in North America report no history of bat bite or scratch and 33% report no history of bat contact.
  - Although rare, there are reported cases of laboratory aerosolization and infection from transplanted organs.
- The virus replicates in muscle tissue and binds to acetylcholine receptors at the neuromuscular junction.
  - The virus continues moving through nerves to the spinal cord where infection of the dorsal ganglia leads to pain. It rapidly multiplies in the brain and passes to the salivary glands where it is shed abundantly during the incubation period.

RISK FACTORS
- Professions or activities with exposure to potentially infected (wild or domestic) animals (e.g., animal handlers, lab workers, veterinarians, cave explorers)
- Travel to countries where canine rabies is endemic
Most U.S. cases are associated with bat exposure. Internationally, rabies is widespread in both domestic and feral dogs. Human-to-human transmission has occurred through transplantation of cornea, solid organs, and other tissues.

**GENERAL PREVENTION**

- **Pre-exposure vaccination**
  - For high-risk groups (veterinarians, animal handlers, wildlife rangers, and certain laboratory workers)
  - Consider pre-exposure vaccination for travelers to areas (such as North Africa) that have increased risk of rabies from domestic animals.

- **Source control and avoidance**
  - Immunization of dogs and cats has led to a dramatic decrease in U.S. cases since the 1950s.
  - Contact animal control and avoid approaching or handling wild (or domestic) animals exhibiting strange behaviors.

- **Post-exposure prophylaxis**
  - Seek treatment promptly if bitten, scratched, or in contact with saliva from potentially infected animal.
  - Prevent infection by prompt post-exposure treatment.
  - Consider post-exposure prophylaxis for individuals in direct contact with bats.
  - Hospital contacts of patients infected with rabies do not require postexposure prophylaxis unless there has been exposure through mucous membranes or an open wound (including a bite) to saliva, cerebrospinal fluid (CSF), or brain tissue from the infected patient.
  - Hospitalized patients should be placed in contact isolation with gowns, gloves, goggles, and masks.

**DIAGNOSIS**

In most cases, the diagnosis is clinical based on the history and physical exam.

**HISTORY**

- History of animal exposure; however, most patients do not recall exposure
- Five stages (may overlap):
  - Incubation period: time between bite and first symptoms: usually 10 days to 1 year (average of 20 to 60 days). Incubation is shortest in patients with extensive bites in the head or trunk.
  - Prodrome: lasts 1 to 14 days; symptoms include pain or paresthesia at bite site and nonspecific flulike symptoms, including fever and headache.
  - Acute neurologic period: lasts 2 to 10 days. CNS symptoms dominate; generally 1 of 2 forms:
    - Encephalitic (furious) rabies: occurs in around 80% of cases and begins with brief (~5 minute) episodes of hyperactivity with hydrophobia, aerophobia, hyperventilation, hypersalivation, and autonomic instability; progresses to hallucinations, paralysis, stupor
    - Paralytic (dumb) rabies: occurs in around 20% of cases and paralysis dominates; may be ascending (as in Guillain-Barré syndrome) or may affect limbs differentially; progresses to urinary and fecal incontinence
  - Coma: lasts hours to days; may evolve over several days following acute neurologic period;
may be sudden, with respiratory arrest
– Death: usually occurs within 3 weeks of symptom onset as result of cardio-respiratory arrest
in paralytic rabies; closer to 5–7 days with diaphragmatic paralysis in encephalitic rabies

PHYSICAL EXAM
Findings range from normal exam to severe neurologic findings, including paralysis and coma, depending on the stage of rabies at the time of presentation.

● Assess bite site for excoriation, local swelling, or neuropathic pain.
● Encephalitis—fluctuating consciousness with hyperarousal alternating with lucid periods
● Hydrophobia—Asking the patient to swallow water or offering a glass of water causes spasms of
the accessory muscles of the neck, pharyngeal muscles, and diaphragm.
● Aerophobia—blowing or fanning air on the face causes spasms of the accessory muscles of the
neck, pharyngeal muscles, and diaphragm
   – May exhibit fearful facial expression during these episodes
● Signs of autonomic dysfunction—hypersalivation, hyperhidrosis, anisocoria, mydriasis,
piloerection, and priapism
● Limb weakness may be the presenting symptom with paralytic rabies.
● Neuropathic and/or radicular pain, sensory deficits, seizures may be the presenting symptoms
with bat-variant rabies.

DIFFERENTIAL DIAGNOSIS
● Any rapidly progressive encephalitis; important to exclude treatable causes of encephalitis,
e specially herpes simplex virus
   – Japanese encephalitis, West Nile virus, Eastern equine encephalitis, enterovirus, Nipah virus
● Tetanus
● Botulism
● Substance use disorder with intoxication
● Transverse myelitis
● Guillain-Barré syndrome

DIAGNOSTIC TESTS & INTERPRETATION
● Negative predictive value of laboratory tests are low due to multiple factors including
intermittent shedding, antibody production, and phase of disease.
● Therefore, multiple types of samples are tested to increase chances of a positive test: serum,
saliva, CSF, skin biopsy.

ALERT
Contact state or local health department in suspected rabies testing so that collection and
transportation of labs (skin biopsy, saliva, serum, and CSF) to the Centers for Disease Control
(CDC) can be safely arranged.

Initial Tests (lab, imaging)
● Lumbar puncture
   – White blood cell count is normal or shows moderate pleocytosis; protein normal or
   moderately elevated
   – Rabies antibody titer
● Serum
   – Rabies antibody titer
- Saliva
  - Reverse transcriptase and polymerase chain reaction (RT-PCR) or isolation of the virus by immunofluorescence
- Skin biopsy from nape of neck
  - To detect rabies through RT-PCR and/or direct fluorescent antigen (DFA), biopsy needs to include hair follicles.
- Corneal smear stains are positive by immunofluorescence in 50% of patients.
- Hyponatremia is common.
- Head CT scan shows normal or nonspecific findings consistent with encephalitis.
- MRI can help rule out other forms of encephalitis.
- Postmortem diagnoses can be confirmed by brain tissue analysis with DFA or RT-PCR.

**Follow-Up Tests & Special Considerations**

Testing/observing the suspected rapid animal:
- No case of human rabies in the U.S. has been attributed to a dog, cat, or ferret that has remained healthy throughout the standard 10-day period of confinement after an exposure.
- Submit the brain tissue from at least two different locations, preferably the brainstem and the cerebellum of the suspected rabid animal, for direct fluorescent antibody testing if possible.

**Test Interpretation**

- Encephalitis may be found on brain biopsy. Other abnormal findings (e.g., brainstem, midbrain, cerebellum) often found only postmortem.
- Negri bodies—round or oval eosinophilic inclusions found in the cytoplasm of the pyramidal cells of Ammon’s horn, and the Purkinje cells of the cerebellum

**TREATMENT**

There is no specific treatment once symptoms have developed. Neither rabies vaccine nor rabies immunoglobulin improve the prognosis.

**GENERAL MEASURES**

Thorough wound cleansing with soap and water is first line of treatment. Irrigate wound with virucidal agent, such as povidone-iodine, if available.

**MEDICATION**

**ALERT**

- Assess need for postexposure prophylaxis with local wound care, rabies vaccination, and rabies immunoglobulin (RIG) based on circumstances of possible exposure, consulting public health officials for recommendations.
- Increased risk:
  - Bites involving skin puncture are at higher risk than a scratch; saliva exposure is a risk only if it comes in contact with an open wound or mucous membranes.
  - Wild or domestic animals unavailable for quarantine
  - Bat exposure
  - Hybrid animals of wild and domestic species (e.g., wolf-dog)
  - Unprovoked attack (Feeding a wild animal is considered a provoked attack)
Management:
- Bites from cats, dogs, and ferrets that can be watched for 10 days do not require prophylaxis unless animal shows signs of illness.
- Skunks, foxes, bats, raccoons, and most carnivores are high risk, and prophylaxis should begin promptly unless animal can be captured and euthanized for pathologic evaluation.
- For rodents or livestock, consult local public health authorities before initiating prophylaxis.

Postexposure prophylaxis
- Passive vaccination: rabies immunoglobulin (RIG, HyperRAB) 20 IU/kg administered once. Infiltrate RIG around the wound if possible. Administer remaining RIG IM. Do not administer RIG using the same syringe or into the same anatomic site as vaccine.
- Active vaccination: rabies vaccine, human diploid cell vaccine (HDCV) or rabies vaccine adsorbed (RVA) or purified chick embryo cell vaccine IM in the deltoid. Give the first dose, 1 mL, as soon as possible after exposure. The day of the first dose is designated day 0. Give additional 1-mL doses on days 3, 7, 14, and 28. For children, use the anterolateral aspect of the thigh and avoid the gluteal area (1).
- Immunosuppression alters immunity after vaccination. Immunosuppressive drugs should be avoided during post-exposure prophylaxis if possible. If post-exposure prophylaxis is given to an immunosuppressed patient, check serum samples for the presence of rabies virus–neutralizing antibody to assess response to vaccination.

Previously vaccinated patients: Administer an initial 1-mL IM dose of vaccine immediately and an additional 1-mL dose 3 days later. RIG is not necessary in these patients.

Preexposure vaccination: for people in high-risk groups, such as veterinarians, animal handlers, wildlife rangers, certain laboratory workers, and those spending time in foreign countries where rabies is enzootic:
- Primary pre-exposure: Three IM 1-mL injections of HDCV or RVA in deltoid area on days 0, 7, and 21 or 28
- Pre-exposure boosters: For people at risk of exposure to rabies, test serum every 2 years. Administer preexposure booster of 1-mL IM if immunity is waning. If titer cannot be obtained, a booster can be administered instead.

Contraindications: None for post-exposure treatment.

Adverse effects: 0.6% of people develop mild serum sickness reaction following HDCV boosters. Mild local and systemic reactions are common following vaccination. Do not interrupt immunization series with mild reactions.

Consider need for tetanus prophylaxis as well.

Pregnancy Considerations
- Pregnancy is not a contraindication to post-exposure prophylaxis, although it has not been specifically studied in the United States.
- Rabies vaccination is not associated with a higher incidence of spontaneous abortion, premature births, or fetal abnormalities.

ADDITIONAL THERAPIES
- Symptomatic rabies necessitates a palliative approach and should be focused on analgesia, sedation and seizure control.
- Although there have been attempts to discover a treatment, none currently exist.
- Milwaukee protocol: experimental treatment using ketamine, midazolam, and amantadine (originally included ribavirin but no longer recommended) (2)[C]. One patient who did not
receive pre- or postexposure prophylaxis recovered from clinical rabies in 2004 after being treated with medically induced coma and amantadine.

- Control cerebral artery vasospasm (with an agent such as nimodipine) (2)[C].
- Fludrocortisone and hypertonic saline if needed to maintain normal sodium level

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

After primary vaccination, serologic testing is necessary only if the patient has a severe illness or takes immunosuppressive medication to ensure titers to vaccination.

**PATIENT EDUCATION**

- Use screens over ventilation areas in the roof to secure from bats.
- Avoid exposure to wild mammalian species known to carry rabies and report potential exposures immediately.
- Educate children to avoid contact with unknown domestic and wild animals.

**PROGNOSIS**

- No post-exposure failures in the United States since the 1970s
- If untreated, rabies has the highest case fatality rate of any infectious disease; generally considered to be 100% fatal once symptoms develop.
- To date, fewer than 20 cases of survival from clinical rabies. Almost all received some form of pre- or post-exposure immunization.

**COMPLICATIONS**

- During latter stages of disease, multiorgan failure ensues:
  - Cardiac arrhythmias, heart failure, cardiac arrest, myocarditis
  - Hyperventilation, hypoxemia, respiratory depression, aspiration pneumonia, neurogenic pulmonary edema
  - Syndrome of inappropriate antidiuretic hormone, diabetes insipidus
  - Gastrointestinal hemorrhage
- In the very rare cases where patients survive, there are varying reports of neurologic impairment.

**REFERENCES**

**ADDITIONAL READING**

Bites, Animal and Human

CODES

ICD10
- A82.9 Rabies, unspecified
- Z20.3 Contact with and (suspected) exposure to rabies

CLINICAL PEARLS
- Caused by an RNA virus Rhabdoviridae; transmitted by infected animal saliva
- Rabies is a vaccine-preventable virus.
- Rabies is rare in US; more common in other areas, particularly Africa and Asia.
  - Seek immediate treatment if exposed to scratch, bite, or saliva of potentially infected animal (e.g., feral dog, bat, fox, raccoon, or other wild mammals).
  - Postexposure prophylaxis consists of 3 steps: local wound cleansing, passive immunization with rabies immunoglobulin, and active immunization with HDCV.
  - Consider postexposure prophylaxis for those reporting direct contact with bats, unless it can be verified that an exposure did not occur.
  - Contact local health department for all suspected cases and particularly if sending antemortem samples to the CDC.
BASICS

DESCRIPTION

- Definitions (vary by jurisdiction on local, state, and national levels):
  - Rape (a legal term), sexual assault (a medical term), or sexual violence (a general term): any form of sexual activity that occurs without consent between a victim and perpetrator(s)/suspect(s)
  - Rape/sexual assault/sexual violence: may be associated with the use of force and/or threats, alcohol, and/or illicit and/or prescription drugs
  - Intimate partner violence (IPV): aggression and/or abuse that occurs within a close relationship between a current or former dating partner and/or spouse that can include the following types of behavior:
    - Sexual violence
    - Physical violence
    - Psychological aggression
    - Stalking
  - Military sexual trauma (MST): any form of sexual activity (or sexual harassment) that occurs without consent between a victim and perpetrator(s)/suspect(s) during military service
  - Rape crisis syndrome is a historical term that has previously been utilized to define what is now known as an acute stress reaction (ASR), acute stress disorder (ASD), and/or a post-traumatic stress disorder (PTSD) in persons exposed to sexual violence.
    - Psychological responses to sexual violence, identical to other forms of trauma, can range anywhere from transient and non-debilitating to chronic and debilitating.
    - The neurobiology and traumatic impact of sexual violence on victims is complex; associated with a profound flight, fight, and/or freeze-related fear response as well as hormonal cascade (involving catecholamines, cortisol, opiates, and oxytocin) and the use of primitive brain structures (e.g., the prefrontal cortex, amygdala, hippocampus) and can trigger the development of numerous post-traumatic psychological, emotional, physical, and social effects
  - Acute stress reaction (ASR): a transient reaction to traumatic stress (e.g., sexual violence) that may develop simultaneously with and/or last less than 3 days after a traumatic event; may be temporarily debilitating but resolves rapidly with simple measures (e.g., reassurance, ensuring safety, and/or rest); not a Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) diagnosis
  - Acute stress disorder (ASD): an acute reaction to traumatic stress (e.g., sexual violence) that has a duration of 3 days to 1 month with symptoms that result in functional impairment and/or cause significant distress; see the DSM-5 for further diagnostic criteria.
    - Diagnostic clusters of symptoms include: intrusion symptoms, arousal symptoms, dissociative symptoms, negative mood, and avoidance symptoms
  - Post-traumatic stress disorder (PTSD): a chronic reaction to traumatic stress (e.g., sexual violence) that has a duration of greater than 1 month with symptoms that result in functional
impairment and/or cause significant distress; see the DSM-5 for further diagnostic criteria.

• Common sequelae of sexual violence: physical injuries (e.g., contusions and lacerations), psychological conditions (e.g., ASR, ASD, PTSD, depression, anxiety, suicidal and/or homicidal ideation(s), eating and/or sleeping disorders, substance and/or alcohol abuse, a decreased self-esteem/worth/confidence), reproductive concerns (e.g., unplanned pregnancy, sexually transmitted infections [STIs] sexual dysfunction), and somatic reactions (e.g., chronic pelvic pain and/or headaches, recurrent abdominal pain, fibromyalgia)

EPIDEMIOLOGY
• In United States, more than 33% of women and nearly 25% of men have reported experiencing sexual violence during their lifetimes.
• ~1.5 million women and 834,700 men are victims of sexual violence annually in the U.S.
• Legal and medical care-related expenses associated with sexual violence cost the U.S. more than $127 billion per year, which exceeds every other form of crime.
• The following populations are especially vulnerable:
  – Adolescents and young children
  – Persons with disabilities
  – Elderly adults
  – Those with a low socioeconomic status and/or that are homeless
  – Sex workers
  – People living in institutions/areas of conflict/training environments
• Predominant age
  – The incidence of sexual violence peaks in those 11 to 24 years of age
    – Adolescent victims of sexual violence have a greater frequency of anogenital injuries
• Predominant sex: female > male
  – Females:
    – 33% of female victims first experienced sexual violence before age 18; 13% of whom first experienced it before age 10
  – Males:
    – 25% of male victims first experienced sexual violence before age 18; 25% of whom first experienced it before age 10
• Only 16–38% of victims of sexual violence report to law enforcement, and 17–43% of victims obtain a medical evaluation.
• 33% of victims of sexual violence never report it to their primary care providers.
• Most victims of sexual violence know or have had an acquaintance with their perpetrators/suspects.
• Episodes of sexual violence for both male and female victims have predominantly resulted from male perpetrators/suspects.
• Nearly 50% of all episodes of sexual violence have been associated with alcohol use.

RISK FACTORS
• History of sexual violence, psychological aggression, physical violence, and/or stalking
• Early initiation of sexual activity
• Engagement in high-risk sexual behavior
• Exposure to familial and/or environmental violence
• Consumption of alcohol
• Use of illicit drugs
Belief in traditional gender roles

**GENERAL PREVENTION**

- Primary prevention: Promoting gender equality, teaching skills to prevent sexual violence, providing opportunities to empower and support women and girls, and creating protective environments.
  - Strategies include mobilizing men and boys as allies, empowering bystanders, teaching social-emotional learning and safe intimate relationship skills, promoting health sexuality, strengthening economic supports and leadership opportunities for girls and women, and improving safety and monitoring in schools, workplaces, and communities.
- Secondary prevention: The United States Preventive Services Task Force (USPSTF) recommends screening all women of childbearing age for intimate partner violence (IPV) and referring women who screen positive for interventional services.
  - The HARK screening tool, which includes questions that assess if a patient has felt humiliated (H) and/or afraid (A), and been raped (R) and/or kicked (K) within the past year, is 81% sensitive and 95% specific for IPV; as well as clinically useful (1)[B].

**DIAGNOSIS**

Subjective history of, and/or objective physical exam findings concerning for, sexual violence
- The PTSD Checklist for DSM-5 (PCL-5) is useful for PTSD, and 86% sensitive and 63% specific

**HISTORY**

- Patients that present to medical care after experiencing sexual violence should receive a comprehensive medical and, if desired, forensic evaluation.
  - Medical and forensic histories and exams should ideally be performed by providers with specialized training in providing medical care (e.g., Sexual Assault Nurse Examiners [SANEs], Sexual Assault Forensic Examiners [SAFEs], and Sexual Assault Medical Forensic Examiners [SAMFES]).
- States usually require the completion of specific forms for documenting the history of a victim and/or suspect/perpetrator of sexual violence.
- Avoid questioning that may imply that a patient is at fault and/or be interpreted as investigative.
- Record answers in the patient’s own words, and request clarification for unclear terminology.
- Describe all types of sexual contact, whether it was actual/attempted and with/without use of force.
- Inquire about any alcohol and/or illicit drug use before and/or after the episode of sexual violence.
- Document the time of occurrence of activities that could potentially alter biological specimens (e.g., taking a bath or shower, using a douche or mouthwash, brushing teeth, eating/drinking, and/or changing clothes).
- Obtain a thorough gynecologic history, including the LMP, last sexual contact, use of contraception, and prior surgery.

**PHYSICAL EXAM**

- Document all atypical physical findings and/or signs concerning for sexual and/or physical
trauma.

- Document the patient’s mental status and emotional state during the exam.
- Obtain the patient’s consent prior to each step of the examination; is mandatory but also empowers patients.
- Pending the patient’s preferences, may obtain confidential medical photographs (i.e., on a secure digital camera that is reserved solely for use on this unique patient population) prior to swabbing and exam.
- May use a UV light (Wood’s lamp) and orange-tinted forensic goggles to detect biological specimens on clothing and/or skin prior to swabbing and physically examining the patient.

**ALERT**

- A medical and forensic SAFE Kit (previously referred to as a “rape kit”) contains sterile cotton swabs that can be used to collect biological specimens from the oropharyngeal cavity, anogenital regions, and other bodily sites as clinically indicated. Detailed instructions are provided within the kit.
- Perform a complete oropharyngeal, genital, and rectal exam; and assess for physical signs concerning for physical and sexual trauma, blood and/or other biological fluids, and/or foreign objects.
  - Use a nonlubricated, water-moistened speculum for female patients.

**DIFFERENTIAL DIAGNOSIS**

Consensual sexual activity

**DIAGNOSTIC TESTS & INTERPRETATION**

- Obtain a urine or serum pregnancy test.
- Record wet mount/prep results while screening for bacterial vaginosis and trichomaniasis, and note the presence or absence of sperm.
- Drug and/or alcohol testing as clinically indicated.
- Diagnostic testing for sexually transmitted infections (STIs) is medically indicated but not required prior to prescribing treatment. Recommend screening for chlamydia, gonorrhea, bacterial vaginosis, trichomoniasis, HIV, hepatitis B, and syphilis.
- If strangulation occurred obtain CT angiogram (CTA)

**TREATMENT**

**GENERAL MEASURES**

- All cases of sexual violence must be reported immediately to the appropriate law enforcement agency.
- With a victim’s permission, enlist the help of personnel from local support agencies (e.g., sexual violence/“rape crisis” support centers) and in-house social services (e.g., SANEs/SAFEs/SAMFEs, victim advocates, sexual assault response and care coordinators, sexual assault care providers, behavioral health specialists, chaplains).
- Administer tetanus prophylaxis, if clinically indicated.
- Discuss STI exposure with victim and test/treat.
- Review potential for unplanned pregnancy, and discuss pregnancy termination-related options.
- Evaluate for psychological sequelae, and refer for evaluation by behavioral health specialists.
MEDICATION

First Line

- The Centers for Disease Control and Prevention’s (CDC’s) 2015 Sexually Transmitted Diseases Treatment Guidelines recommend empirically and prophylactically treating STIs (especially gonorrhea, chlamydia, trichomoniasis, bacterial vaginosis, hepatitis B, and human papilloma virus [HPV]), as well as considering treatment for human immunodeficiency virus (HIV) and syphilis, depending on a patient’s level of risk.
- Cultures not required before treatment.
- Patients should be advised that any STI testing and results will be noted in their medical record, and if their case goes to trial, these records will have to be made available to the suspect/perpetrator’s attorney. Patients should be given the option to forego STI testing and receive empiric and prophylactic STI treatment.
- Gonorrhea: (adult dosing) ceftriaxone 250 mg IM single dose; (pediatric dosing) a) weight < or = 45 kg: ceftriaxone 25–50 mg/kg IV or IM single dose (not to exceed 125 mg), b) weight >45 kg: refer to adult dosing
- Chlamydia: (adult dosing) azithromycin 1 g PO single dose, or doxycycline 100 mg PO BID for 7 days; (pediatric dosing) a) age > or = 8 years: refer to adult dosing, b) age <8 years with weight > or = 45 kg: azithromycin 1 g PO single dose, c) age <8 years with weight <45 kg: erythromycin base or ethylsuccinate 50 mg/kg/day PO divided into 4 doses daily for 14 days
- Trichomoniasis: (adult and pediatric dosing) metronidazole 2 g PO single dose or tinidazole 2 g PO single dose
- Bacterial vaginosis: (adult and pediatric dosing) metronidazole 500 mg PO BID for 7 days, or metronidazole gel 0.75% 5 g (one full applicator) intravaginally daily for 5 days, or clindamycin cream 2% 5 g (one full applicator) intravaginally nightly for 7 days
- HIV: A low likelihood of HIV transmittance during sexual violence, prescribe non-occupational post-exposure prophylaxis (nPEP) high risk HIV exposure (e.g., suspect HIV status is positive and/or history of IV drug use).
  - nPPEP options:
    o Tenofovir Disoproxil Fumarate 300 mg with Emtricitabine 200 mg (Truvada) PO once daily for 28 days plus
    o Raltegravir (Isentress) 400 mg PO twice daily for 28 days or
    o Tenofovir Disoproxil Fumarate 300 mg with Emtricitabine 200 mg (Truvada) PO once daily for 28 days plus
    o Dolutegravir (Tivicay) 50 mg PO once daily for 28 days
    o Pregnant: Dolutegravir is not recommended due to risk of neural tube defect. Highest risk in first 28 days. Obtain ID consult.
    o Non-pregnant women: Use caution prescribing nPEP for nonpregnant women of childbearing age who are not using effective birth control.
  - Treatment most effective within 4 hours of sexual assault and can reduce HIV transmission by ~80%.
- Hepatitis B: hepatitis B immunoglobulin 0.06 mL/kg IM single dose, and initiate a 3-dose–total hepatitis B virus immunization series (1st dose administered at initial exam, 2nd dose 1–2 months after 1st dose, and 3rd dose 4–6 months after 1st dose)
  - No treatment is indicated if the victim has received a complete hepatitis B vaccine series and has documented levels of immunity.
- HPV: HPV vaccination is recommended for females who have been the victims of sexual
violence 9 to 26 years of age, and male victims 9 to 21 years of age.
- Age 9 to 12 years: 1st dose administered at initial exam, and 2nd dose 6–12 months after 1st dose
- Age >12 years: 1st dose administered at initial exam, 2nd dose 1–2 months after 1st dose, and 3rd dose 6 months after 1st dose
- Syphilis: Evidence does not currently support the empiric and prophylactic treatment of patients with a low-risk of developing syphilis. However, patients with a high-risk of contracting syphilis may be treated with benzathine penicillin G 2.4 million units IM single dose.
- Common psychological sequelae of sexual violence:
  - ASR and ASD: brief sessions of individualized trauma-focused psychotherapy treatments that have a component of cognitive restructuring and/or exposure
  - PTSD: Selective serotonin reuptake inhibitors (SSRIs) are the 1st-line medical treatment, in addition to long-term and individualized psychotherapy treatments.

Pregnancy Considerations
- Discuss unplanned pregnancy prevention and termination-related options. Listed in order of effectiveness.
  - Yuzpe regimen (100 μg of ethinyl estradiol and 0.5 mg levonorgestrel [or equivalent doses of other combined oral contraceptive pills]) PO q12h × 2 doses. It is 75–80% effective, rarely used due to decreased efficacy and GI side effects (e.g., nausea and emesis).
  - Levonorgestrel 0.75 mg q12h PO × 2 doses (Plan B), or 1.5 mg PO single dose (Plan B One-Step) lower incidence of GI side effects. Effective up to 72 hours, less effective in overweight women.
  - Ulipristal acetate 30 mg PO single dose (Ella; does not contain hormones) effective up to 120 hours. It is preferred in overweight women.
  - Copper IUD 313.4 mg IU single device (Paragard) is effective up to 120 hours after intercourse. Most effective emergency contraceptive method.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Contact law enforcement and social services.
- Most pediatric victims require admission and/or transitional care placement until social services can evaluate home environments.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Patients should be re-evaluated in 7–10 days for care (including pregnancy re-testing and counseling) with gonorrhea & chlamydia at 1-2 weeks; syphilis & HIV at 6, 12 and 26 weeks; HPV wart testing at 4–8 weeks

PATIENT EDUCATION
- National Sexual Assault Telephone Hotline: (800) 656-HOPE (4673); https://www.rainn.org/about-national-sexual-assault-telephone-hotline
- Veterans Crisis Line: 1 (800) 273-8255;
PROGNOSIS
- Acute phase (usually 1–3 weeks):
  - Shaking, pain, wound healing, mood swings, appetite loss, crying; feelings of grief, shame, anger, fear.
- Late/chronic phase (also known as reorganization):
  - May develop a fear of intercourse being alone; nightmares, sleep disorders, flashbacks, anxiety, depression, post-traumatic stress disorder (PTSD), and somatic complaints (e.g., nonspecific abdominal pain).
- Recovery phase (may be prolonged):
  - Psychotherapy results in faster recovery

COMPLICATIONS
- Unplanned pregnancy
  - In U.S., sexual violence-related pregnancy >32,000 unplanned pregnancies each year.
- Psychological conditions
  - Nearly 33% of all women with PTSD have a history of sexual violence.

- T74.22XA Child sexual abuse, confirmed, initial encounter
- Z04.41 Encounter for exam and obs following alleged adult rape
RAYNAUD PHENOMENON
Kelsey E. Phelps, MD

BASICS

DESCRIPTION
- Idiopathic intermittent episodes of vasoconstriction of digital arteries, precapillary arterioles, and cutaneous arteriovenous shunts in response to cold, emotional stress, or blunt trauma
  - A triphasic color change of the fingers (occasionally the toes, rarely nipples) is the principal physical manifestation.
    o The initial color is white from extreme pallor, then blue from cyanosis, and finally with warming/vasodilatation, the skin appears red.
    o Thumbs are rarely involved.
  - Swelling, throbbing, and paresthesias are associated symptoms.
  - Primary
    o 80% of patients have primary disease.
    o Episodes are bilateral and nonprogressive.
    o Diagnosis confirmed if after 2 years of symptoms no underlying connective tissue disease develops
  - Secondary
    o Progressive and asymmetric
    o Vascular spasm is more frequent and more severe over time. Ulceration is rare; gangrene does not develop; 13% progress to digital fat pad atrophy and ischemic fingertip changes.
    o Typically associated with an underlying connective tissue disorder
- System(s) affected: hematologic, lymphatic, immunologic, musculoskeletal, dermatologic, exocrine

Pregnancy Considerations
- Raynaud phenomenon can appear as breast pain in lactating women (1).
- Positive breast milk bacterial culture distinguishes mastitis from Raynaud phenomenon.

Geriatric Considerations
Initial appearance of Raynaud phenomenon after age 40 years suggests underlying connective tissue disease.

Pediatric Considerations
Associated with systemic lupus erythematosus (SLE) and scleroderma

EPIDEMIOLOGY

Incidence
- Primary
  - Predominant age: 14 years; ~1/4 begin >40 years
  - Predominant sex: female > male (4:1)
- Secondary
  - Predominant age: >40 years
  - Predominant sex: no gender predilection
Prevalence
- Primary: 3–12% of men; 6–20% of women (based on clinical history)
- Secondary: ~1% of population

ETIOLOGY AND PATHOPHYSIOLOGY
Unknown. Dysregulation of vascular control mechanisms leads to imbalance between vasodilation and vasoconstriction. There is a reduced endothelin-dependent vasodilation activity and an increased vasoconstriction in peripheral vessels by overproduction of endothelin-1. 5-HT\textsubscript{2} serotonin receptors may be involved in secondary Raynaud phenomenon. Platelet and blood viscosity abnormalities in secondary disease contribute to ischemic pathology.

Genetics
Some studies suggest dominant inheritance pattern. ~1/4 of patients with primary condition also have a first-degree relative with Raynaud phenomenon.

RISK FACTORS
- Existing autoimmune or connective tissue disorder
- End-stage renal disease with hemodialysis may increase risk if a steal phenomenon develops in association with the arterial-venous shunt.
- Primary and secondary disease associated with elevated homocysteine levels
- Smoking is not associated with increased risk of Raynaud phenomenon but may worsen symptoms.

GENERAL PREVENTION
- Avoid cold exposure.
- Tobacco cessation
- No relationship has been established between Raynaud phenomenon and vibratory tool use.

COMMONLY ASSOCIATED CONDITIONS
Secondary Raynaud
- Scleroderma; SLE; polymyositis
- Sjögren syndrome; occlusive vascular disease
- Cryoglobulinemia

DIAGNOSIS
HISTORY
- Primary
  - Symmetric attacks involving fingers
  - Family history of connective tissue disorder
  - Absence of tissue necrosis, ulceration, or gangrene
  - If after ≥2 years of symptoms, no abnormal clinical or laboratory signs have developed, secondary disease is unlikely.
- Secondary
  - Onset typically after 40 years of age
  - Asymmetric episodes more intense and painful
  - Arthritis, myalgias, fever, dry eyes and/or mouth, rash, or cardiopulmonary symptoms
– History of medication and/or recreational drug use
– Exposure to toxic agents
– Repetitive trauma

PHYSICAL EXAM
Pallor (whiteness) of fingertips with cold exposure, then cyanosis (blue) and then redness and pain with warming
- Ischemic attacks evidenced by demarcated or cyanotic skin limited to digits; usually starts on one digit and spreads symmetrically to remaining fingers of both hands. The thumb is typically spared.
- Rarely involves other tissues (e.g., tongue) (2,3)
- Beau lines: transverse linear depressions in nail plate on most or all fingernails that occurs after exposure to cold or any insult that disrupts normal nail growth
- Livedo reticularis: mottling of the skin of the arms and legs; benign and reverses with warming

Primary
- Normal physical exam
- Nail bed capillaries have normal appearance: Place 1 drop of grade B immersion oil on skin at base of fingernail and view capillaries with handheld ophthalmoscope at 10 to 40 diopters.

Secondary
- Skin changes, arthritis, and abnormal lung findings suggest connective tissue disease.
- Ischemic skin lesions: ulceration of finger pads (autoamputation in severe, prolonged cases)
- Nail bed capillary distortion including giant loops, avascular areas, and increased tortuosity
- Abnormal Allen test (Have patient open and close hand several times and then tightly into a fist. Sequentially occlude the ulnar and radial arteries while the patient opens hand to reveal the return of color as a measure of circulation.)

DIFFERENTIAL DIAGNOSIS
- Thromboangiitis obliterans (Buerger disease): primarily affects men; smoking related
- Rheumatoid arthritis (RA)
- Progressive systemic sclerosis (scleroderma): Raynaud phenomenon precedes other symptoms.
- SLE
- Carpal tunnel syndrome; thoracic outlet syndrome
- Hypothyroidism
- CREST syndrome (calcinosis cutis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasias)
- Cryoglobulinemia; Waldenström macroglobulinemia
- Acrocyanosis
- Polycythemia
- Occupational (e.g., especially from vibrating tools, masonry work, exposure to polyvinyl chloride)
- Drug induced (e.g., clonidine, ergotamine, methysergide, amphetamines, bromocriptine, bleomycin, vinblastine, cisplatin, cyclosporine)

DIAGNOSTIC TESTS & INTERPRETATION
Provocative test (e.g., ice water immersion) unnecessary

Primary
- Antinuclear antibody: negative
- ESR: normal

- Secondary
  - Tests for secondary causes (e.g., CBC, ESR)
  - Positive autoantibody has low positive predictive value for connective tissue disease (30%).
  - Antibodies to specific autoantigens (e.g., scleroderma with anticentromere or antitopoisosmerase antibodies)
  - Videocapillaroscopy is gold standard (200 times magnification).

**Follow-Up Tests & Special Considerations**
Periodic assessments for a connective tissue disorder

**Diagnostic Procedures/Other**
Diagnosis is determined by history and physical exam.

### TREATMENT
Assess using a Raynaud Condition Score.

**GENERAL MEASURES**
- Dress warmly, wear gloves, avoid cold temperatures.
- During attacks, rotate the arms in a windmill pattern or place the hands under warm water or in a warm body fold to alleviate symptoms.
- Tobacco cessation
- Avoid β-blockers, amphetamines, ergot alkaloids, and sumatriptan.
- Temperature-related biofeedback may help patients increase hand temperature. 1-year follow-up is no better than control.
- Finger guards to protect ulcerated fingertips

**MEDICATION**

**First Line**
- Calcium channel blockers (CCBs). Nifedipine is the best studied and most frequently used.
- Nifedipine: 30 to 180 mg/day (sustained-release form); seasonal (winter) use is effective with up to 75% of patients experiencing improvement.
- Compatible with breastfeeding
- Contraindications: allergy to drug, pregnancy, CHF
- Precautions: may cause headache, dizziness, lightheadedness, edema, or hypotension
- Significant possible interactions
  - Increases serum level of digoxin

**Second Line**
- Amlodipine (5 to 10 mg/day) and nicardipine are effective and may have fewer adverse effects.
- No data exist to support switching CCB if initial drug is ineffective.
- Small studies support benefit from losartan and fluoxetine.
- Phosphodiesterase type-5 inhibitors (sildenafil, vardenafil) may reduce symptoms without increasing blood flow.
• Parenteral iloprost, a prostacyclin, in low doses (0.5 ng/kg/min over 6 hours), has improved ulcerations with severe Raynaud phenomenon when CCBs failed. Oral prostacyclin has not proven useful.
• Nitroglycerin patches may be helpful, but use is limited by the incidence of severe headache. Nitroglycerin gel has shown promise as a topical therapy.
• Topical sildenafil cream may also improve digital arterial blood flow in patients with secondary Raynaud phenomenon (4).
• Prazosin (1 to 2 mg TID) is the only well-studied $\alpha_1$-adrenergic receptor blocker with modest effect; adverse effects may outweigh any benefit.
• ACE inhibitors are no longer recommended.

**ISSUES FOR REFERRAL**
If an underlying disease is suspected, consider rheumatology consultation for evaluation and treatment.

**ADDITIONAL THERAPIES**
• Botulinum toxin somewhat effective in reducing vasospastic episodes, frequency of attacks, rest pain, and helping to promote digital ulcer healing (5)[C]
• Aspirin
• Digital or wrist block with lidocaine or bupivacaine (without epinephrine) for pain control
• Short-term anticoagulation with heparin if persistent critical ischemia, evidence of large-artery occlusive disease, or both

**SURGERY/OTHER PROCEDURES**
Surgical intervention is rare in Raynaud phenomenon. Effect of cervical sympathectomy is transient; symptoms return in 1 to 2 years. Digital fat grafting is a novel modality that has shown improved symptomatology and evidence of measurably increased perfusion in several cases (6)[C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
• Ginkgo biloba with unclear benefit (7)[B]
• Fish oil supplements may increase digital systolic pressure and time to onset of symptoms after exposure to cold; not proven in controlled trials
• Vitamin D supplementation led to improvement in self-reported symptoms in vitamin D–deficient patients with Raynaud phenomenon (8)[B].
• Evening primrose oil reduced severity of attacks in one study.
• Oral arginine is no better than placebo.
• Biofeedback is not helpful.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Avoid exposure to cold; reassess for secondary causes.

**Patient Monitoring**
Manage fingertip ulcers and rapidly treat infection.
DIET
No special diet

PATIENT EDUCATION
- Tobacco cessation
- Avoid triggers (e.g., trauma, vibration, cold).
- Dress warmly; wear gloves.
- Warm hands when experiencing vasospasm.

PROGNOSIS
- Attacks may last from several minutes to a few hours.
- 2/3 of attacks resolve spontaneously.
- ~13% of Raynaud patients develop a secondary disorder, typically connective tissue diseases.

COMPLICATIONS
- Primary: very rare
- Secondary: gangrene, autoamputation of fingertips

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithm: Raynaud Phenomenon
CODES

ICD10
- I73.00 Raynaud’s syndrome without gangrene
- I73.01 Raynaud’s syndrome with gangrene

CLINICAL PEARLS
- Raynaud phenomenon is a clinical diagnosis.
- Provocative testing is not recommended.
- Initial presentation of Raynaud phenomenon after age 40 years suggests underlying (secondary) disease.
- Raynaud phenomenon is a cause of breast pain in lactating women.
- Primary Raynaud phenomenon is symmetric; secondary Raynaud phenomenon is asymmetric.
- Primary Raynaud phenomenon is treated with hand warming and avoiding cold exposure.
- Digital ulcers are not normal and always merit a workup for secondary disease.
- Acute digital ischemia is a medical emergency.
**REACTIVE ARTHRITIS (REITER SYNDROME)**

Douglas W. MacPherson, MD, MSc–CTM, FRCPC

---

**BASICS**

Reiter syndrome is a seronegative, multisystem, inflammatory disorder classically involving joints, the eye, and the lower genitourinary (GU) tract. It is a postinfectious autoimmune process. Axial joint (e.g., spine, sacroiliac joints) and dermatologic manifestations are common (1)(C),(2)[C].

**DESCRIPTION**

The classic triad includes arthritis, conjunctivitis/iritis, and either urethritis or cervicitis (“can’t see; can’t pee; can’t bend my knee”).

- The epidemiology is similar to other reactive arthritides, characterized by sterile joint inflammation associated with infections originating at nonarticular sites. A fourth feature (dermatologic involvement) may include buccal ulceration, balanitis, or a psoriasiform skin eruption. (Having only two features does not rule out the diagnosis.)

- Two forms of Reiter syndrome:
  - Sexually transmitted: Symptoms emerge 7 to 14 days after exposure to *Chlamydia trachomatis* and other sexually acquired pathogens.
  - Postenteric infection (including traveler’s diarrhea)

- In individuals with new or frequent sexual partners, the triggering infection is likely sexually transmitted (rather than enteric).

- In individuals with a history of recent enteric illness, the triggering event is more likely to be a bacterial enteric infection than sexual transmission.

- System(s) affected: musculoskeletal, renal/urologic, dermatologic/exocrine

- Synonym(s): idiopathic blennorrheal arthritis; arthritis urethritica; urethro-oculo-synovial syndrome; Fiessinger-Leroy-Reiter disease; reactive arthritis

**Pediatric Considerations**

Juvenile rheumatoid arthritis (RA) has many of the same clinical features as Reiter syndrome.

**Pregnancy Considerations**

No special considerations; usual drug precautions

---

**EPIDEMIOLOGY**

**Incidence**

- Predominant age: 20 to 40 years
- Predominant sex: male > female
- 0.2–1% incidence after bacterial dysentery outbreaks
- Complicates 1–2% of nongonococcal urethritis cases
- ~3–5 cases per 100,000 individuals per year.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- The pathophysiology of all the seronegative reactive arthritis syndromes and the immunologic role of infectious diseases as precipitants for clinical illness are incompletely understood.
Proinflammatory cytokines lead to synovitis. Toll-like receptors (TLR) have been implicated in the recognition of gram-negative lipopolysaccharide as part of the disease cascade.

- Avoiding precipitant infections and early management of multiorgan inflammation is important. Antibiotic treatment following onset of syndrome does not appear to benefit inflammatory joint, eye, or urinary tract symptoms.
- C. trachomatis is the most common sexually transmitted infection associated with Reiter syndrome.
- Dysentery-associated Reiter syndrome follows infection with Shigella, Salmonella, Yersinia, and Campylobacter spp. Enteric-associated Reiter syndrome is more common in women, children, and the elderly than the postvenereal form.

**Genetics**

HLA-B27 tissue antigen present in 60–80% of patients, suggesting a genetic predisposition

**RISK FACTORS**

- New or high-risk sexual contacts 1–4 weeks before the onset of clinical presentation; the primary infection may be subclinical and undiagnosed.
- Food poisoning or bacterial dysentery

**GENERAL PREVENTION**

- The immune-response characteristics of this syndrome make avoidance of infectious precipitants the most important general precaution (and potentially the most difficult to achieve).
- Safe sexual practices; proper food and water hygiene

**COMMONLY ASSOCIATED CONDITIONS**

- Enteric disease
  - Shigellosis; Salmonellosis; Campylobacteriosis
  - Enteric infection with Yersinia spp.
- Urogenital infection
  - Chlamydia urethritis/cervicitis (3)[C]
  - Mycoplasma or Ureaplasma spp.
- HIV/AIDS

**DIAGNOSIS**

- Clinical presentation with joint, eye, and GU inflammation (“classic triad”) and negative serologic testing for rheumatoid factor
- Classic symptoms not always present
- HLA-B27 testing is not required for diagnosis.

**HISTORY**

The presence of the clinical syndrome plus

- Diarrhea, dysentery, urethritis, or genital discharge and appropriate exposure history
- Exposure risks, including travel or migration history and potential infectious exposure
- Arthritis associated with urethritis for >1 month (84% sensitive; 98% specific for diagnosis)
- Urethritis occurs 1 to 15 days after sexual exposure.
- Reiter syndrome onset within 10 to 30 days of either enteric infection or sexually transmitted
infection (STI)
- Mean duration of symptoms is 19 weeks

PHYSICAL EXAM
- Musculoskeletal
  - Asymmetric arthritis (especially knees, ankles, and metatarsophalangeal joints)
  - Enthesopathy (inflammation at tendinous insertion into bone, such as plantar fasciitis, digital periostitis, polydactylitis, and Achilles tendinitis)
  - Spondyloarthropathy (spine and sacroiliac joint involvement)
- Urogenital tract
  - Urethritis; prostatitis; cystitis (rare)
  - Balanitis
  - Cervicitis: usually asymptomatic
- Eye
  - Conjunctivitis of one or both eyes
  - Occasionally, scleritis, keratitis, and corneal ulceration
  - Rarely, uveitis and iritis
- Skin
  - Mucocutaneous lesions (small, painless superficial ulcers on oral mucosa, tongue, or glans penis)
  - Keratoderma blennorrhagica (hyperkeratotic skin lesions of palms and soles and around nails—can be mistaken for psoriasis)
- Cardiovascular: occasionally, pericarditis, murmur, conduction defects, and aortic incompetence
- Nervous system: rarely, peripheral neuropathy, cranial neuropathy, meningoencephalitis, and neuropsychiatric changes
- Constitutional
  - Fever, malaise, anorexia, and weight loss
  - Patient can appear seriously ill (e.g., fever, rigors, tachycardia, and exquisitely tender joints).

DIFFERENTIAL DIAGNOSIS
- Seropositive arthritides: Rheumatoid arthritis
- Ankylosing spondylitis
- Arthritis associated with inflammatory bowel disease
- Psoriatic arthritis
- Juvenile RA
- Bacterial arthritis, including gonococcal
- Rheumatic fever

DIAGNOSTIC TESTS & INTERPRETATION
- Blood
  - Negative rheumatoid factor
  - Leukocyte count: 10,000 to 20,000 cells/mm³
  - Neutrophil predominance
  - Elevated erythrocyte sedimentation rate and/or C-reactive protein
  - Moderate normochromic, normocytic anemia
– Hypergammaglobulinemia

● Synovial fluid
  – Leukocyte count: 1,000 to 8,000 cells/mm$^3$
  – Bacterial culture negative

● Supportive tests
  – Cultures, antigens, or polymerase chain reaction positive for C. trachomatis or stool test positive for Salmonella, Shigella, Yersinia, or Campylobacter species
  – HIV serology positive (acute retroviral syndrome)
  – HLA-B27–positive (not required for diagnosis)
  – Drugs that may alter lab results: Antibiotics may affect isolation of the bacterial pathogens.
  – Rheumatoid factor is negative.

● X-ray
  – Periosteal proliferation, thickening
  – Articular bony spurs; erosions at articular margins
  – Residual joint destruction
  – Syndesmophytes (spine); sacroiliitis

**Diagnostic Procedures/Other**
HLA-B27 histocompatibility antigen: positive in 60–80% of cases in non–HIV-related Reiter syndrome; HLA testing is not required or recommended for diagnosis.

● Screen for STI if clinically indicated.

● Screening for enteric infections is rarely useful and generally not indicated.

**Test Interpretation**

● Seronegative spondyloarthropathy (similar to ankylosing spondylitis, enteric arthritis, and psoriatic arthritis)

● Villous formation within joints; hyperemia, and inflammation

● Prostatitis and seminal vesiculitis

● Skin biopsy similar to psoriasis

---

**TREATMENT**

**GENERAL MEASURES**
Treatment is determined by symptoms.

● Conjunctivitis does not require specific treatment.

● Iritis requires treatment.

● Mucocutaneous lesions do not require treatment.

● Physical therapy (PT) aids recovery.

● Arthritis may become prominent and disabling during the acute phase.

**MEDICATION**

**First Line**

● Symptomatic management: NSAIDs, including indomethacin, naproxen, and others; intra-articular or systemic corticosteroids for refractory arthritis and enteritis

  – Contraindications
    o GI bleeding
- Peptic ulcer, gastritis, or ulcerative colitis
- Renal insufficiency

**Specific treatment of isolated microorganism (4)[A]:**

- **C. trachomatis:** doxycycline 100 mg PO BID for 7 to 14 days (Note: All STIs should be treated whether associated with Reiter syndrome or not.)
- **Salmonella, Shigella, Yersinia, and Campylobacter infections:** ciprofloxacin 500 mg PO BID for 5 to 10 days (Note: Emerging antimicrobial resistance may limit the effectiveness of ciprofloxacin. Antibiotic treatment does not reduce GI symptoms or duration of infection or prevent carrier state.)
- Trials of antibiotic treatment for reactive arthritis have produced mixed results, rendering the efficacy of antibiotics uncertain.

- **GI upset:** antacids
- **Iritis:** intraocular steroids
- **Keratitis:** topical steroids

**Second Line**

- Aspirin or other NSAIDs
- Sulfasalazine is promising but not FDA-approved.
- Methotrexate or azathioprine in severe cases (experimental, not approved or known to be effective); immunosuppressive therapy is relatively contraindicated in HIV-related Reiter syndrome.
- Specialty consultation is recommended, particularly if considering immunomodulatory agents such as sulfasalazine, methotrexate, or azathioprine or for treatment with anti-tumor necrosis factor medications (etanercept and infliximab), which have shown benefit in isolated case reports.
- Role of antibiotics under investigation—currently unproven effectiveness in seronegative arthritides
- No published evidence supports the beneficial effect of antibiotics on the long-term outcome in patients with Reiter syndrome.

**ISSUES FOR REFERRAL**

Joint and eye complications; complex cases—consider consultation with rheumatology; ophthalmology

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Based on severity of disease and associated complications
- Inpatient care may be needed during acute phase.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Activity modification until joint inflammation subsides

**Patient Monitoring**

Monitor clinical response to anti-inflammatory drugs. Observe for complications, particularly with sulfasalazine and immunosuppressive drugs.
PATIENT EDUCATION

- Educate on risk factors for exposure and recurrence.
- Home PT
- National Institute of Arthritis and Musculoskeletal and Skin Diseases: http://www.niams.nih.gov/

PROGNOSIS

Prognosis is poor in cases involving the heel, eye, or heart.

COMPLICATIONS

- Chronic or recurrent disease in 5–50% of patients
- Ankylosing spondylitis develops in 30–50% of patients who test positive for HLA-B27 antigen.
- Urethral strictures
- Cataracts and blindness
- Aortic root necrosis

REFERENCES

ADDITIONAL READING

Ankylosing Spondylitis; Arthritis, Psoriatic; Behçet Syndrome

CODES

ICD10
- M02.30 Reiter’s disease, unspecified site
- M02.39 Reiter’s disease, multiple sites

CLINICAL PEARLS

- Diagnosis of reactive arthritis is based on the clinical presentation of the classic triad of joint, eye, and GU inflammation and negative serologic testing for rheumatoid factor (signs and symptoms may not all be present at the same time).
- Screen for STI (including HIV) if sexually acquired. Enteric studies are rarely clinically indicated.
- Refer patients with a chronic or recurrent course and those who have clinical complications.
- Treatment focuses on symptom relief and treating any underlying infection.
RENAL TUBULAR ACIDOSIS
Jason Kurland, MD

BASICS

DESCRIPTION
Renal tubular acidosis (RTA) is composed of a group of disorders characterized by an inability of the kidney to resorb bicarbonate (HCO$_3^-$)/secrete hydrogen ions, resulting in normal anion gap metabolic acidosis. Renal function (glomerular filtration rate [GFR]) must be normal or near normal.

Several types have been identified:
- Type I (distal) RTA: inability of the distal tubule to acidify the urine due to impaired hydrogen ion secretion, increased back leak of secreted hydrogen ions, or impaired sodium reabsorption (interfering with the generation of negative luminal charge required for hydrogen/potassium secretion); urine pH >5.5
- Type II (proximal) RTA: defect of the proximal tubule in HCO$_3^-$ reabsorption. Proximal tubular HCO$_3^-$ reabsorption is absent; plasma HCO$_3^-$ concentration stabilizes at 12 to 18 mEq/L due to compensatory distal HCO$_3^-$ reabsorption; urine pH <5.5 unless plasma HCO$_3^-$ brought above reabsorptive threshold
- Type III RTA: extremely rare autosomal recessive syndrome due to carbonic anhydrase II deficiency; causes mixed type I and type II RTA, osteopetrosis, cerebral calcification, intellectual disability
- Type IV RTA (hypoaldosteronism): due to aldosterone resistance/deficiency that results in hyperkalemia. Urine pH usually is <5.5.

EPIDEMIOLOGY

Incidence
- Predominant age: all ages
- Predominant sex: male > female (with regard to type II RTA with isolated defect in HCO$_3^-$ reabsorption)

ETIOLOGY AND PATHOPHYSIOLOGY
- Type I RTA
  - Autoimmune diseases: Sjögren syndrome, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), thyroiditis (1)
  - Medications: amphotericin B, lithium, ifosfamide, foscarnet, amiloride, triamterene, trimethoprim (2), pentamidine
  - Obstructive uropathy (hyperkalemic)
  - Genetic: autosomal dominant, autosomal recessive associated with sensorineural deafness
  - Sporadic
  - Other familial disorders: Ehlers-Danlos syndrome, glycogenosis type III, Fabry disease, Wilson disease
  - Hematologic diseases: sickle cell disease (hyperkalemic), hereditary elliptocytosis
  - Toxins: toluene, glue
- Hypercalciuria, diseases causing nephrocalcinosis
- Vitamin D intoxication
- Medullary cystic disease
- Hypergammaglobulinemic syndrome
- Chronic pyelonephritis
- Chronic renal transplant rejection
- Leprosy
- Chronic active hepatitis, primary biliary cirrhosis
- Malnutrition

**Type II RTA**
- Multiple myeloma, other dysproteinemic states
- Amyloidosis
- Medications: acetazolamide, ifosfamide, tenofovir, sulfanilamide, outdated tetracycline, topiramate (3), aminoglycosides
- Familial (cystinosis, tyrosinemia, hereditary fructose intolerance, galactosemia, glycogen storage disease type I, Wilson disease, Lowe syndrome, inherited carbonic anhydrase deficiency)
- Sporadic
- Heavy metal poisoning (e.g., cadmium, lead, mercury, copper)
- Interstitial renal disease
- Paroxysmal nocturnal hemoglobinuria
- Defects in calcium metabolism (hyperparathyroidism)

**Type IV RTA (4)**
- Medications: NSAIDs, ACE inhibitors, ARBs, heparin/LMW heparin (hyperkalemia in 5–10% of patients), ketoconazole, tacrolimus, cyclosporine, spironolactone, eplerenone
- Diabetic nephropathy
- Tubulointerstitial nephropathies
- Primary adrenal insufficiency
- Markedly decreased distal Na⁺ delivery
- Pseudohypoaldosteronism (PHA) (end-organ resistance to aldosterone)
  - PHA type 1
  - PHA type 2 (Gordon syndrome)

**Genetics**
- Type I RTA: hereditary forms due to mutations affecting intercalated cells in collecting tubules (5). May occur in association with other genetic diseases (e.g., Ehlers-Danlos syndrome, hereditary elliptocytosis, or sickle cell nephropathy). The autosomal recessive form is associated with sensorineural deafness.
- Type II RTA: Autosomal dominant form is rare. Autosomal recessive form is associated with ophthalmologic abnormalities and intellectual disability; occurs in Fanconi syndrome, which is associated with several genetic diseases (e.g., cystinosis, Wilson disease, tyrosinemia, hereditary fructose intolerance, Lowe syndrome, galactosemia, glycogen storage disease, metachromatic leukodystrophy)
- Type IV RTA: Some cases are familial, such as PHA type I (autosomal dominant).

**GENERAL PREVENTION**
Careful use/avoidance of causative agents
COMMONLY ASSOCIATED CONDITIONS

- Type I RTA in children: hypercalciuria leading to rickets, nephrocalcinosis
- Type I RTA in adults: autoimmune diseases (Sjögren syndrome, RA, SLE), obstructive uropathy, hypercalciuria
- Type II RTA: Fanconi syndrome (generalized proximal tubular dysfunction resulting in glycosuria, aminoaciduria, hyperuricosuria, phosphaturia, bicarbonaturia)
- Type II RTA in adults: multiple myeloma, carbonic anhydrase inhibitors, aminoglycosides
- Type IV RTA: diabetic nephropathy, solid-organ transplant (due to calcineurin inhibitors)

DIAGNOSIS

HISTORY

- Often asymptomatic (particularly type IV)
- In children: failure to thrive, rickets
- Anorexia, nausea/vomiting, constipation
- Weakness or polyuria (due to hypokalemia)
- Polydipsia
- Osteomalacia in adults

DIFFERENTIAL DIAGNOSIS

- Plasma anion gap should be normal. If not, evaluate for causes of anion-gap metabolic acidosis: ketoacidosis, ingestions (ASA, methanol, ethylene glycol, propylene glycol), lactic acidosis, D-lactic acidosis, uremia, pyroglutamic acid.
- Extrarenal HCO₃⁻ losses
  - Diarrhea
  - Small bowel, pancreatic, or biliary fistulas
  - Urinary diversion (e.g., ureterosigmoidostomy, ileal conduit)
- Acidosis of chronic renal failure (develops when GFR ≤20 to 30 mL/min)
- Excessive administration of acid load via chloride salts, including dilutional acidosis via normal saline (NaCl, HCl, NH₄Cl, lysine HCl, CaCl₂, MgCl₂)

DIAGNOSTIC TESTS & INTERPRETATION

- Electrolytes reveal hyperchloremic metabolic acidosis.
- Plasma anion gap normal (anion gap = Na – [Cl + HCO₃⁻]). Normal values (in mEq/L) depend on analyzer used: infants/children 5 to 15; adolescents/adults 4 to 12; must increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in albumin <4 g/dL (3)[B]
- Plasma K⁺: low in type I (if due to impaired distal H⁺ secretion/increased H⁺ back leak), type II; high in type IV, type I (if due to impaired distal Na⁺ reabsorption)
- Plasma HCO₃⁻ (in untreated RTA): type I: <10 to 20 mEq/L; type II: 12 to 18 mEq/L (1); type IV: >17 mEq/L
- BUN/Cr normal or near normal (rules out renal failure as cause of acidosis)
- Urinalysis: urine pH inappropriately alkaline (>5.5) despite metabolic acidosis in type I; also in type II if HCO₃⁻ above reabsorptive threshold (12 to 18 mEq/L)
- Urine culture: Rule out UTI with urea-splitting organism (may elevate pH) and chronic infection.
Urine anion gap (UAG; urine [Na\(^+\) + K\(^+\)] – Cl\(^-\) on a random specimen): reflects unmeasured urine anions, so inversely related to urine NH\(_4\)\(^+\) (or acid) excretion. Positive UAG in an acidemic patient indicates impaired renal acid excretion. Urine Na\(^+\) >25 mEq/L required for accurate interpretation of UAG; results tend to be:
- Negative in HCO\(_3\) losses due to diarrhea, UTI caused by urea-splitting organisms, and other extrarenal causes of nonanion gap metabolic acidosis
- Variable in type II RTA
- Positive in type I RTA, type IV RTA
- Positive in impaired acid excretion due to renal failure

- Urine calcium
  - High in type I
  - Typically normal in type II
- Drugs that may alter lab results
  - Diuretics
  - Sodium bicarbonate (and other alkali)
  - Cholestyramine

**Initial Tests (lab, imaging)**
Serum electrolytes; urinalysis; urine sodium, urine potassium, urine chloride (to calculate UAG)

**Diagnostic Procedures/Other**
- Helpful to measure urine pH on fresh sample with pH meter for increased accuracy instead of dipstick. Pour film of oil over urine to avoid loss of CO\(_2\) if pH cannot be measured quickly.
- Urine NH\(_4\)\(^+\) excretion (Anion gap only provides a qualitative estimate.)
- Urinary acidification (impaired in type I RTA) can be assessed by oral administration of furosemide and fludrocortisone; patients with type I RTA unable to reduce urine pH to <5.3
- Fractional excretion of HCO\(_3\) >15% during HCO\(_3\) infusion (type II RTA) \(^{(1)}\)

**Test Interpretation**
- Nephrocalcinosis
- Nephrolithiasis
- Rickets
- Osteomalacia, osteopenia
- Findings of an underlying disease causing RTA

**TREATMENT**

**MEDICATION**

**First Line**
- Provide oral alkali to raise serum HCO\(_3\) to normal. Start at a low dose and increase until HCO\(_3\) is normal. Give as sodium bicarbonate (7.7 mEq NaHCO\(_3\)/650 mg tab), sodium citrate (oral solution, 1 mEq HCO\(_3\) equivalent/mL), sodium/potassium citrate (oral solution), or potassium citrate (tablet, powder, or oral solution: 2 mEq K/mL, 2 mEq HCO\(_3\)/mL), depending on need for potassium.
Type I RTA: Typical doses 1 to 2 mEq/kg/day (in adults), 3 to 4 mEq/kg/day (in children) HCO$_3^-$ equivalent divided 3 to 4 times per day (require much higher doses if HCO$_3^-$ wasting is present); may require K$^+$ supplementation (1)[C]

Type II RTA: Typical doses 10 to 15 mEq/kg/day HCO$_3^-$ equivalent, divided 4 to 6 times per day. Very difficult to restore plasma HCO$_3^-$ to normal, as renal HCO$_3^-$ losses increase once plasma HCO$_3^-$ is corrected above resorptive threshold. Exogenous HCO$_3^-$ increases K$^+$ losses, requiring supplemental K$^+$. Often need supplemental PO$_4^-$ and vitamin D due to proximal PO$_4^-$ losses; may add thiazide diuretic to induce mild hypovolemia, which increases proximal Na$^+$/HCO$_3^-$ reabsorption

Type IV RTA: Avoid inciting medications; restrict dietary K$^+$. May augment K$^+$ excretion with loop diuretic, thiazide diuretic, or Kayexalate. Correcting hyperkalemia increases activity of the urea cycle, augmenting renal ammoniagenesis and adding substrate for renal acid excretion (1)[C]. If necessary, 1 to 5 mEq/kg/day alkali divided 2 to 3 times per day; if mineralocorticoid deficiency, fludrocortisone: 0.1 to 0.3 mg/day

Precautions
- Sodium-containing compounds will increase urinary calcium excretion, potentially increasing the risk of nephrolithiasis.
- Mineralocorticoids and sodium-based alkali may lead to hypertension and/or edema.
- Aluminum-containing medications (antacids, sucralfate) should be avoided if solutions containing citric acid are prescribed because citric acid increases aluminum absorption.
- Sodium bicarbonate may cause flatulence because CO$_2$ is formed, whereas citrate is metabolized to HCO$_3^-$ in the liver, avoiding gas production.

Second Line
Thiazide diuretics may be used as adjunctive therapy in type II RTA (after maximal alkali replacement) but are likely to further increase urinary K$^+$ losses.

SURGERY/OTHER PROCEDURES
If distal RTA is due to obstructive uropathy, surgical intervention may be required.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Generally managed as outpatient; inpatient if acidosis severe, patient unreliable, emesis persistent, or infant with severe failure to thrive

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Electrolytes 1 to 2 weeks following initiation of therapy, monthly until serum HCO$_3^-$ corrected to desired range, and then as clinically indicated
- Monitor underlying disease as indicated.
- Poor compliance common due to 3 to 6 times per day alkali dosing schedule

DIET
Varies based on serum K$^+$ level and volume status

PATIENT EDUCATION
- National Kidney Foundation: https://www.kidney.org/

PROGNOSIS
- Depends on associated disease; otherwise, good with therapy
- Transient forms of all types of RTA may occur.

COMPICATIONS
- Nephrocalcinosis, nephrolithiasis (type I)
- Hypercalciuria (type I)
- Hypokalemia (type I, type II if given HCO$_3$)
- Hyperkalemia (type IV, some causes of type I)
- Osteomalacia (type II due to phosphate wasting), osteopenia (due to buffering of acid in bone)

REFERENCES

CODES

ICD10
N25.89 Oth disorders resulting from impaired renal tubular function

CLINICAL PEARLS
- Consider RTA in cases of normal anion gap metabolic acidosis with normal/near-normal renal function.
- Type I RTA: urine pH >5.5 in setting of acidemia; positive UAG; acidemia can be severe.
- Type II RTA: urine pH <5.5 unless HCO$_3$ raised above reabsorptive threshold (12 to 18 mEq/L)
- Type IV RTA: most common subtype; hyperkalemia; urine pH <5.5; acidemia usually mild
- Treatment includes avoidance of inciting causes, provision of oral alkali (HCO$_3$ or citrate), and
measures to supplement (type II, many type I) or restrict (type IV) potassium.
RESPIRATORY DISTRESS SYNDROME, ACUTE (ARDS)
Ashley Twyman, MD • Clayton Smith, MD, FACP

BASICS

DESCRIPTION
- Acute respiratory distress syndrome (ARDS) is defined as the onset of acute hypoxemia within 7 days of a known clinical insult or new or worsening respiratory symptoms with bilateral opacities (patchy, diffuse, or homogenous) consistent with pulmonary edema on imaging. This respiratory failure is not explained by cardiac failure or fluid overload, and no evidence of left atrial hypertension is present.
- Severity of ARDS depends on oxygenation of the blood. It is measured with a ratio of partial pressure of arterial oxygen (\(\text{PaO}_2\)) to fraction of inspired oxygen (\(\text{FiO}_2\)) at a positive end-expiratory pressure (PEEP) or continuous positive airway pressure (CPAP) of at least 5 cm \(\text{H}_2\text{O}\).
  - Mild: \(200 \text{ mm Hg} < \frac{\text{PaO}_2}{\text{FiO}_2} \leq 300 \text{ mm Hg}\)
  - Moderate: \(100 \text{ mm Hg} < \frac{\text{PaO}_2}{\text{FiO}_2} \leq 200 \text{ mm Hg}\)
  - Severe: \(\frac{\text{PaO}_2}{\text{FiO}_2} \leq 100 \text{ mm Hg}\)
- Synonym(s): acute lung injury; increased-permeability pulmonary edema; noncardiac pulmonary edema
- Systems affected: pulmonary, cardiovascular

EPIDEMIOLOGY

Incidence
- Incidence of ARDS is highly variable and under-recognized.
- Highest incidence rate is in United States of 78.9/100,000 person-years.

ETIOLOGY AND PATHOPHYSIOLOGY
- ARDS is a response to alveolar injury, which can be direct or indirect, that produces diffuse alveolar damage.
  - Direct
    - Aspiration of gastric contents
    - Pneumonia (bacterial, viral, fungal, or opportunistic infections)
    - Air, fat, or amniotic fluid emboli
    - Near drowning
    - Pulmonary contusion
    - Inhalation injury
  - Indirect
    - Sepsis (nonpulmonary source)
    - Shock
    - Transfusion
    - Major burn injury
    - Nonthoracic trauma
    - Drug overdose
Progression of the diffuse alveolar damage in ARDS is divided into three phases.
- Exudative phase: The initial highly inflammatory phase when alveolar macrophages are activated due to lung injury, leading to complement activation, release of pro-inflammatory mediators, and activation of neutrophils. This causes epithelial–endothelial barrier disruption leading to intra-alveolar and extra-alveolar flooding with fluid, and is followed by hyaline membrane formation leading to alveolar collapse.
- Fibroproliferative phase: characterized by fibroblasts, myofibroblasts, and alveolar epithelial cell (ACE) II mediated repair. Formation of new matrix, differentiation into ACE I, and formation of cellular junctions begin which leads to expression of aquaporin and ion channels, aiding in the reabsorption of fluid.
- Fibrotic phase: Not every patient progresses to this phase; is related to prolonged mechanical ventilation and associated with increased mortality.

GENERAL PREVENTION
Good ICU practices like low tidal volumes in all mechanically ventilated patients, early resuscitation and antibiotics for sepsis, restrictive use of blood products, and intensivist involvement may help prevent nosocomial ARDS.

COMMONLY ASSOCIATED CONDITIONS
- Pneumonia, sepsis, and aspiration of gastric contents lead to 85% of ARDS cases, with sepsis being the most common cause.
- Other causes include:
  - Trauma
  - Burns
  - Cardiothoracic surgery
  - Pancreatitis
  - Inhalational injuries and near drowning
  - Transfusion-related acute lung injury (TRALI)
  - Shock
  - Medication toxicity

DIAGNOSIS
HISTORY
Precipitating event (see “Etiology and Pathophysiology”) followed by abrupt onset of respiratory distress

PHYSICAL EXAM
- Tachypnea and tachycardia during the first 12 to 24 hours; increase in oxygen requirements
- Manifestations of underlying disease
- Decrease breath sound along with rales
- Absence of exam findings of cardiac failure
DIFFERENTIAL DIAGNOSIS
- Bilateral pneumonia
- Congestive heart failure
- Interstitial and airway diseases
- Hypersensitivity pneumonitis
- Endobronchial tuberculosis
- Diffuse alveolar hemorrhage
- Veno-occlusive disease
- Mitral stenosis: intravascular volume overload
- Drug-induced lung disease especially vascular leak syndrome with immunotherapy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Initial labs should include a CBC, CMP, and ABG
  - ABG will show evidence of severe hypoxemia.
- ECG: sinus tachycardia; nonspecific ST–T wave changes
- Chest x-ray (CXR): normal heart size; bilateral opacities; air bronchograms common
- Chest CT scan: diffuse interstitial opacities

Follow-Up Tests & Special Considerations
- Consider blood cultures and Gram stain and culture of sputum or endotracheal aspirate.
- Consider transthoracic echocardiography (TTE) in patient when the diagnosis of cardiac failure cannot be excluded.
- Consider bronchoscopy when the cause of ARDS cannot be clearly identified.
- Different biomarkers are being studied to help identify subtypes of ARDS. In the future, they may be in use to help guide therapy.

Diagnostic Procedures/Other
- Invasive monitoring of pulmonary artery wedge pressure (PAWP) has fallen out of favor after clinical trials have shown no increased benefit and more catheter-related complication (1)[A].
- Measuring esophageal pressure with a manometer to estimate pleural pressure allows for adjustment of PEEP to achieve a positive end-expiratory transpulmonary pressure gradient, an approach that is increasingly used in clinical care and especially useful in the morbidly obese (2)[C].

Test Interpretation
With introduction of Berlin criteria, a diagnosis of ARDS can be made with a calculated PaO₂/FIO₂ of ≤300 mm Hg with radiologic evidence of new bilateral infiltrates, after ruling out other causes of acute changes in respiratory status & cardiac failure.

TREATMENT

GENERAL MEASURES
- Identify and treat the cause of ARDS.
- Central venous line and arterial line insertion
- Ventilatory support generally requires endotracheal intubation and use of PEEP with lung
protective ventilation.

- Using tidal volumes of 6 mL/kg of predicted body weight with a plateau pressure goal of ≤30 cm H₂O has shown decrease in mortality in comparison to higher volumes (3)[A].
- Tidal volumes can be reduced to 4 mL/kg if plateau pressures exceed 30 cm H₂O (2)[A].
- Respiratory rate can be set to maintain adequate minute ventilation. Permissive hypercapnia allowed so long as pH >7.30 (3)[A]. Recent data support lower respiratory rates (2)[C].
- No clear guideline for PEEP has been established. No clinical trial has shown consistent benefit of high PEEP. There is possible benefit of reduced mortality in subgroup of patients with moderate to severe ARDS with high PEEP (2)[C].

In patients with early moderate to severe ARDS (PaO₂/FiO₂ <150 mm Hg), use of neuromuscular blockade with sedation compared with placebo resulted in decrease in mortality. This possibly prevents breath stacking and patient-ventilator dyssynchrony and increases efficacy of lung protective ventilation (4)[A].

- Also in patients with moderate to severe ARDS (PaO₂/FiO₂ <150 mm Hg and PEEP >5 cm H₂O) who had been intubated for <36 hours, prone positioning has shown decrease in mortality and early extubation in comparison to supine. In prone positioning group, patients were placed in prone position for 16 consecutive hours/day for up to 28 days or until PaO₂/FiO₂ ratio of ≥150 mm Hg, with a PEEP of ≤10 cm H₂O and an FiO₂ of ≤0.6 for >4 hours while in the supine position. The benefit of prone position is due to reduction in deleterious effects of positive pressure ventilation on nondependent and less injured airspaces (5)[A].

- Extracorporeal membrane oxygenation (ECMO) is reserved for severe ARDS after standard supportive measures have failed. One randomized controlled trial suggested improved mortality in properly selected individuals with ARDS referred to an ECMO center (2)[C].

- In patients with very severe ARDS (PaO₂/FiO₂ <80 mm Hg), the use of early ECMO versus conventional mechanical ventilation that included ECMO as a rescue therapy had no difference in 60-day mortality (6)[A].

MEDICATION
No single medication or combination of medications prevents or improves clinical outcomes in ARDS. Treatment is supportive while addressing the underlying cause.

ISSUES FOR REFERRAL
- All patients with ARDS should be cared for in an ICU with appropriately trained staff.
- Pregnant patients with ARDS also should be followed by a high-risk perinatologist or obstetrician.

ADDITIONAL THERAPIES
- For fluid management, central venous pressure (CVP) can be used to estimate fluid status. Liberal fluid management strategy targeting CVP of 10 to 14 cm H₂O was compared to conservative fluid management strategy targeting CVP of 4 cm H₂O. Conservation approach led to increased ventilator-free days and decreased stay in ICU with no change in mortality (1)[A].
- High-frequency oscillation ventilation showed increased mortality in a clinical trial, although a meta-analysis suggested some benefit in patients with PaO₂/FiO₂ <60 mm Hg (2)[C].
- Airway pressure release ventilation may improve oxygenation but no mortality benefit (2)[C].
Noninvasive ventilation in patients with severe hypoxemia may increase the risk of ventilation-induced lung injury in ARDS (2)[C].

Corticosteroids may improve airway pressures, oxygenation, and especially in pneumonia, infiltrates on radiography, but there is not a consistent mortality benefit in ARDS. There is likely potential harm when started later in course after 14 days (2)[C].

Inhaled nitric oxide, surfactant, statins, nonsteroidal anti-inflammatory agents, antioxidants, albuterol, and neutrophil elastase inhibitor have not shown any benefit in clinical trials (2)[C].

Clinical trials are underway for dexamethasone, vitamin D, aspirin, mesenchymal stem cells, and other therapies.

Focus of research is now to identify different subtypes of ARDS and treat according to pathophysiology.

Pregnancy Considerations
Supportive care while identifying the underlying cause of ARDS continues to be important in the management of pregnant women with ARDS. However, fetal well-being, possible need for delivery, and physiologic changes associated with pregnancy must be considered.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
All patients with ARDS should be managed in an intensive care unit (ICU) setting.

- Lung protective ventilation while providing adequate PEEP
- Consider prone positioning and paralysis if \( \text{PaO}_2/\text{FiO}_2 \) <120 to 150 mm Hg.
- If failing initial supportive measures, consider early referral to an ECMO center.
- Monitoring blood gases especially after changing ventilator settings
- If perfusion is inadequate after restoration of intravascular volume (e.g., septic shock), vasopressor therapy is indicated.
- Early physical therapy
- Nursing may include any or all of the following:
  - Skin, eye, and mouth care
  - Deep vein thrombosis (DVT) prophylaxis
  - Stress ulcer prophylaxis
  - Suctioning of endotracheal tube
  - Adequate care while changing position of patient from supine to prone and vice versa
  - Ensure adequate level of sedation and/or paralysis while on mechanical ventilation.
  - Tracheostomy care
  - Explain all procedures to patient and family; reduce anxiety.
- Discharge criteria
  - Resolution or improvement of underlying precipitant, improving respiratory status, and return to baseline oxygen status
  - Nutrition counseling

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Driving pressure and static lung compliance are important measures of lung mechanics.
- Daily labs are needed until the patient is no longer critical.
Daily CXRs are not needed but should be ordered when evaluating for endotracheal tube placement, the presence of progressing infiltrates, catheter placement, and complications of mechanical ventilation (e.g., air leaks).

**DIET**
For nutrition, trophic and full-calorie enteral nutrition have shown no difference in mortality, whereas early parenteral nutrition might be harmful (2)[C].

**PATIENT EDUCATION**

**PROGNOSIS**
- Mortality rate is 40% with significant increase across the severity categories.
- Mortality is 34.9% in mild ARDS, 40.3% in moderate, and 46.1% in severe ARDS.

**COMPLICATIONS**
- Following are short-term complications:
  - Barotrauma
  - Nosocomial infection
  - Delirium
  - Catheter-related infection
  - DVT
  - Gastrointestinal bleeding due to stress ulcer
  - Poor nutrition
  - Multiple organ dysfunction syndrome
  - Death
- ARDS can have long-term complications that are not dependent on severity of ARDS but on age and comorbidities of patients.
- Following can be long-term sequelae:
  - Pulmonary dysfunction
  - Reduced health-related quality of life
  - Reticular pattern/ground glass opacities on radiographic imaging
  - Neuropsychological disability, such as depression and PTSD

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

J80 Acute respiratory distress syndrome

CLINICAL PEARLS

- ARDS is the acute onset of hypoxemia secondary to alveolar injury with a PaO$_2$/FiO$_2$ ≤300 mm Hg and bilateral infiltrates on chest x-ray.
- Identify and treat the underlying cause along with lung protective approach to mechanical ventilation.
- Low tidal volume (6 mL/kg with plateau pressure goal of ≤30 cm H$_2$O), adequate PEEP, and respiratory rate along with fluid conservative approach. Prone positioning and paralytics can be considered in PaO$_2$/FiO$_2$ <150 mm Hg.
BASICS

DESCRIPTION
- Neonatal respiratory distress syndrome (NRDS) is a disorder primarily of prematurity manifest by respiratory distress.
- System(s) affected: respiratory
- Synonym(s): hyaline membrane disease; surfactant deficiency

ALERT
A disorder of the neonatal period

EPIDEMIOLOGY
Incidence
- >90% incidence in infants born ≤28 weeks’ gestation
- 1% all newborns, 10% of preterm infants
- Inversely proportional to gestational age
- Gender: slight male predominance
- Eighth leading cause of infant death in United States in 2013: 13.3 infant deaths per 100,000 live births (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Impaired surfactant synthesis and secretion
  - Usually secondary to deficient surfactant production in immature lungs
  - Leads to low lung compliance, low lung volume, and increased lung resistance
- High oxygen exposure and barotrauma during treatment can cause further damage to alveolar epithelium.

Genetics
No known genetic pattern

RISK FACTORS
- Premature birth
- Infants of diabetic mothers
- Perinatal asphyxia
- History of RDS in a sibling
- Chorioamnionitis
- Cesarean delivery

GENERAL PREVENTION
- Prevention of premature birth:
  - Education
  - Regular prenatal care
  - Management of maternal medical conditions
Promote healthy behaviors during pregnancy focusing on:
- Diet
- Exercise
- Avoidance of exposure to tobacco smoke, alcohol, and illegal drugs

Antenatal corticosteroids: for women at risk for premature birth between 24 and 34 weeks’ gestation, including those with ruptured membranes and multiple gestations (2)[C]

COMMONLY ASSOCIATED CONDITIONS
Patent ductus arteriosus

DIAGNOSIS

HISTORY
- Preterm neonates with worsening respiratory distress beginning at or shortly after birth and progressing over first few hours of life
- Early interventions can modify classic course

PHYSICAL EXAM
- Tachypnea
- Grunting
- Nasal flaring
- Subcostal and intercostal retractions
- Cyanosis
- Decreased breath sounds
- Pallor
- Diminished pulses
- Peripheral edema
- Decreased urine output

DIFFERENTIAL DIAGNOSIS
- Bacterial pneumonia
- Transient tachypnea of newborn
- Interstitial lung disease
- Persistent pulmonary hypertension
- Cyanotic congenital heart disease

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Arterial blood gases (ABGs)
  - Evaluate for evidence of acid–base abnormalities (respiratory acidosis, metabolic acidosis), hypoxemia, and hypercarbia.
- Chest x-ray (CXR):
  - Diffuse reticulogranular pattern (ground-glass appearance)
  - Air bronchograms
  - Low lung volumes

Follow-Up Tests & Special Considerations
Complete blood count
Blood culture
Blood glucose

**Diagnostic Procedures/Other**
- Echocardiogram: Consider if murmur is present to evaluate for patent ductus arteriosus (PDA) and contribution to lung disease due to L → R shunting.
- Lung pathology (autopsy findings)
  - Macroscopically: uniformly ruddy, airless appearance of lungs
  - Microscopically: diffuse atelectasis and hyaline membranes (eosinophilic and fibrinous membrane lining air spaces)

**TREATMENT**

**GENERAL MEASURES**
- Respiratory Support (3)[C]
  - If no respiratory failure: early initiation of continuous positive airway pressure (CPAP)
  - If respiratory failure: Intubate, ventilate as needed, and administer pulmonary surfactant
- Respiratory monitoring options
  - Noninvasive
    - Transcutaneous monitor or end tidal CO₂ monitor
    - Pulse oximetry: target >90% to <95% O₂ saturation
  - Invasive
    - Umbilical artery catheter placement
      - Direct sampling of ABGs
- Empiric antibiotic therapy with ampicillin and gentamicin pending evaluation of blood cultures
- Supportive care:
  - Thermoneutral environment
  - Maintain adequate perfusion
  - Optimize fluid and electrolyte balance (avoid overhydration)
  - Routine use of diuretics is not indicated
  - Provide for nutritional needs

**MEDICATION**
- Pulmonary surfactant (4)[A]
  - Poractant alfa (Curosurf)—porcine lung minced extract
  - Calfactant (Infasurf)—bovine lung lavage extract
  - Beractant (Survanta)—bovine lung minced extract
  - Each surfactant has specific protocols for delivery; consult local standards
  - Administer within first 30–60 minutes of life; should be balanced with less invasive forms of respiratory support
  - Strong evidence for use with gestational age <30 weeks
  - Side effects
    - Bradycardia
    - Hypotension
    - Airway obstruction/endotracheal tube blockage with administration
Rapid changes in tidal volume (due to increased compliance) can cause a pneumothorax and small risk of pulmonary hemorrhage.

- Transient adverse effects indicate surfactant administration should be temporarily stopped until neonate is stable and dosing can be continued.
  - Contraindications: presence of congenital anomalies incompatible with life beyond neonatal period; infant with laboratory evidence of lung maturity.

- Caffeine: increases respiratory drive
- No indication for inhaled nitrous oxide

**ISSUES FOR REFERRAL**
Comorbid conditions associated with prematurity
- PDA (cardiology consult)
- Necrotizing enterocolitis (NEC) (gastroenterology)
- Retinopathy of prematurity (ROP) (ophthalmology)

**ADDITIONAL THERAPIES**
Treat associated problems of prematurity.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- All neonates with respiratory distress require immediate evaluation, monitoring, and treatment in the delivery room with transfer to a neonatal intensive care unit.
- Supportive care
  - Thermoneutral environment
  - Respiratory monitoring
  - Establish relationship with family to provide education and emotional support.
- Discharge criteria
  - Should have stable vital signs and pulse oximetry before discharge
  - Medical home and support services should be in place.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Following discharge, infants should be followed closely by their physicians to monitor growth and respiratory symptomatology.

**DIET**
As clinically indicated

**PATIENT EDUCATION**
- Educate parents regarding the risks in subsequent pregnancies.
- Advise parents regarding potential issues with chronic lung disease.

**PROGNOSIS**
- Prognosis and outcome are highly dependent on gestational age; significant neurodevelopmental delays in almost half infants ≤25 weeks gestation (5)
- Survival rare in infants <25 weeks gestation (6)

**COMPLICATIONS**
Complications specific to NRDS
- Pneumothorax
- Chronic lung disease, bronchopulmonary dysplasia (BPD)
- Pulmonary interstitial edema (PIE)

Additional complications may occur related to therapeutic interventions and comorbid conditions.

REFERENCES

ADDITIONAL READING

CODES
ICD10
P22.0 Respiratory distress syndrome of newborn
CLINICAL PEARLS

- Neonatal respiratory distress syndrome (NRDS) is a disorder primarily of prematurity manifest by respiratory distress.
- Early treatment with continuous positive airway pressure (CPAP) or pulmonary surfactant can modify clinical course.
- Prognosis and outcome are highly dependent on gestational age.
RESPIRATORY SYNCYTIAL VIRUS (RSV) INFECTION
Sahil Mullick, MD • Zehra Dahlvani, MD

BASICS
Respiratory syncytial virus (RSV) is a medium-sized, membrane-bound RNA virus that causes acute respiratory tract illness in patients of all ages. The most clinically significant disease occurs in infants and children <3 years old. Significant disease also occurs in the elderly and immunocompromised patients.

DESCRIPTION
A major cause of upper respiratory tract infection (URTI) or lower respiratory tract infection (LRTI/bronchiolitis) illness
- In adults, RSV causes URTI.
- In infants and children, RSV causes URTI and LRTI (bronchiolitis and pneumonia-LRTI).

Pediatric Considerations
- 90–95% of children are infected by the age of 24 months; reinfection is common.
- Leading cause of pediatric bronchiolitis (50–90%)
- Premature infants are at increased risk for severe acute RSV infection.

EPIDEMIOLOGY
- Seasonality: Highest incidence of RSV in the United States occurs between December and March.
- Morbidity: RSV infection leads to >100,000 annual hospitalizations. In the United States, there are an estimated 2.1 million outpatient visits for RSV in children <5 years; the most hospitalizations are in the first 3 months of life.
- Mortality: Deaths associated with RSV are uncommon. Children with complex chronic conditions account for the majority of deaths, and the relative contribution of RSV infection to their deaths is unclear (1).

Incidence
- 4–5 million children under the age of 5 years are impacted by RSV illness annually. Of these, 125,000 are hospitalized.
- 177,000 hospitalizations in elderly patients are attributable to RSV. 14,000 annual deaths are attributable to RSV in the elderly.

ETIOLOGY AND PATHOPHYSIOLOGY
- RSV-induced bronchiolitis causes acute inflammation, edema, and necrosis of small airway epithelium, air trapping, bronchospasm, and increased mucus production.
- RSV develops in the cytoplasm of infected cells and matures by budding from the plasma membrane.
- Infection spreads through droplets (airborne or personal contact) that inoculate the nasal epithelium.

Genetics
- A genetic predisposition to severe RSV infections may be associated with polymorphisms in
cytokine- and chemokine-related genes, including CCR5; IL-4; IL-8, IL-10, and IL-13.
- Infants with transplacentally acquired antibody against RSV are not fully protected against infection but may have milder symptoms.

**RISK FACTORS**
- Risk factors for severe disease
  - Prematurity
  - Age <12 weeks
  - Underlying cardiopulmonary disease
  - Immunodeficiency
- Other risk factors
  - Low socioeconomic status
  - Exposure to environmental air pollutants
  - Child care attendance
  - Severe neuromuscular disease
  - Adults: occupational exposure to young children, hospital staff, teachers, and daycare workers

**GENERAL PREVENTION**
- Hand hygiene is the most important step to prevent the spread of RSV.
  - Alcohol-based rubs are preferred. Hand washing with soap and water is acceptable but less effective (2)[B].
- Avoid passive smoke exposure, especially infants and children (3)[A].
- Isolate patients with proven or suspected RSV.
- Palivizumab (Synagis) is a monoclonal antibody directed against the fusion (F) protein of RSV.
  - Prophylactic use is indicated for infants and children <24 months of age with:
    - Chronic lung disease of prematurity requiring medical therapy within 6 months of the start of RSV season
    - Hemodynamically significant congenital heart disease
    - Congenital abnormalities of the airway or neuromuscular disease that compromises handling airway secretions
  - Infants born at ≤29 weeks’ gestation if they are <12 months of age at the start of the RSV season; maintain prophylaxis through end of RSV season.
  - Infants born at 29 to 32 weeks’ gestation if they are <6 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
  - Infants born at 32 to 35 weeks’ gestation who are <3 months of age at the start of the RSV season or who are born during the RSV season if they have one of the following two risk factors:
    - Infant attends child care
    - ≥1 more siblings or other children <5 years of age living permanently in the child’s household
- Dosage: maximum of 5 monthly doses beginning in November or December at 15 mg/kg per dose IM

**COMMONLY ASSOCIATED CONDITIONS**
- Asthma
• Otitis media
• Serious bacterial infection (SBI) in infants and children with concurrent RSV infection is rare.

**DIAGNOSIS**

**ALERT**
In most cases, the diagnosis is clinical. Laboratory and radiologic studies are not routinely necessary (2)[B].

**HISTORY**
• Rhinorrhea and upper respiratory congestion
• Difficulty feeding in infants (due to respiratory effort)
• Increased respiratory rate or signs of increased work of breathing (grunting, flaring, retracting)
• Cough, fever, wheezing
• History of prematurity, secondhand tobacco smoke exposure, daycare, number and age of siblings
• Immunization history
• Family history of respiratory disease

**PHYSICAL EXAM**
• Vital signs: fever, signs of increased work of breathing (tachypnea, grunting, flaring, retracting), apnea, pulse rate (tachycardia >97% for age); pulse oximetry (“5th vital sign”) to assess oxygenation
• Rhinorrhea
• Dry mucous membranes; skin turgor (dehydration)
• Serous otitis or acute otitis
• Pulmonary: wheezing, crackles

**Pediatric Considerations**
Young infants with bronchiolitis may develop apnea with increased risk of prolonged hospitalization, ICU admission, and mechanical ventilation.

**DIFFERENTIAL DIAGNOSIS**
• Mild illness/URTI
  – Other respiratory viral infections: rhinovirus, human metapneumovirus, influenza virus, human bocavirus
  – Allergic rhinitis
  – Sinusitis
• Severe illness/LRTI
  – Bronchiolitis
  – Asthma
  – Pneumonia
  – Foreign body aspiration

**DIAGNOSTIC TESTS & INTERPRETATION**
**Initial Tests (lab, imaging)**
• Routine testing/imaging is not necessary.
– If obtained, white blood cell count normal or elevated
– Virologic tests for RSV, despite high predictive value, rarely change management decisions or outcomes for patients with clinical bronchiolitis.

Given the low risk of systemic bacterial infection, full septic workups are not necessary unless the child is toxic in appearance.

Chest x-ray (CXR) does not predict disease severity or change patient outcomes but may help if a patient does not improve as expected, if the severity of the disease requires further investigation, or if another diagnosis is suspected.

When obtained, typical CXR findings include:
– Hyperinflation and peribronchiolar thickening
– Atelectasis
– Interstitial infiltrates
– Segmental or lobar consolidation

**TREATMENT**

**GENERAL MEASURES**

– Assess hydration status and ability to take fluids orally. Treat dehydration (oral or IV/NG)—particularly in infants.
– Supplemental oxygen, often high flow nasal cannula, if pulse oximetry is persistently <90% in previously healthy patients

**MEDICATION**

**First Line**
No first-line medication for RSV infections; treatment is usually supportive; oxygen as needed

**Second Line**
– Bronchodilators do not improve oxygen saturation, reduce hospital admission after outpatient treatment, shorten the duration of hospitalization, or reduce the time to resolution of illness at home; routine use not recommended (2)[B].
– Nebulized epinephrine is superior to placebo for short-term outcomes in the outpatient setting, particularly in the first 24 hours.
– Glucocorticoids do not alter admissions or length of hospitalization (4)[A].
  – Some data suggest that the combination of dexamethasone and epinephrine may reduce outpatient admissions.
– Montelukast (Singulair) has no effect on the clinical course of acute bronchiolitis.
– Ribavirin, a nucleoside analogue and antiviral agent, has not been shown to be efficacious, particularly in immunocompromised patients.
– There is no current evidence that nebulized rhDNase changes clinical outcomes in children <24 months hospitalized with acute RSV bronchiolitis.
– Reserve antibiotic use for patients who have specific findings suggesting a coexisting SBI.
– Nebulized 3% or 7% saline may reduce the length of stay and improve the clinical severity score in infants hospitalized <3 days with acute viral bronchiolitis.
– Heliox therapy may significantly reduce a clinical respiratory distress score in the first hour after starting treatment for infants with acute bronchiolitis, but there is not a consistent reduction in the rate of intubation, emergency department discharge, or length of treatment for
respiratory distress (4)[A].

ADDITIONAL THERAPIES
- Bulb suctioning of the nares may provide some comfort to infants and allow for easier feeding.
- RSV vaccine is under development (5)[C].

Pediatric Considerations
- Over-the-counter (OTC) cough and cold medications should not be used in children <6 years due to lack of efficacy and the risk of life-threatening side effects.
- Routine bronchodilators should not be used in bronchiolitis. Chest imaging should be avoided in children with uncomplicated bronchiolitis/asthma.

COMPLEMENTARY & ALTERNATIVE MEDICINE
No complementary, alternative, or integrative therapies are of proven benefit in the prevention or treatment of RSV bronchiolitis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Clinical evaluation of respiratory status is critical. Ill-appearing infants should be hospitalized.
- Significant respiratory distress, an oxygen requirement to keep \( \text{SpO}_2 > 90\% \), and the inability to hydrate orally are indications for admission.
- Mechanical ventilation is required in about 5% of infants hospitalized with RSV and 20% of children with underlying congenital heart disease, chronic lung disease, or immunosuppression.
- Universal precautions with gown and glove use are necessary to prevent nosocomial transmission of RSV. Airborne transmission is inefficient; masks/goggles are not necessary (6)[B].
- No set criteria for discharge; patients should be recovering and demonstrate:
  - Stable respiratory status with no oxygen requirement
  - Ability to maintain oral intake and hydration status
  - Home resources adequate to support necessary home therapies, including caretaker’s ability to clear the infant’s airway with bulb suctioning if needed
  - Adequate follow-up and patient education

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Primary care follow-up to ensure resolution

PATIENT EDUCATION
- Parent education—important to emphasize use of alcohol-based hand gels/wash and/or to wash hands with soap and water. Clean surfaces with gloves and avoid daycare/kindergarten during recovery.

PROGNOSIS
Most patients with RSV infection recover fully within 7 to 10 days. Reinfection is common.
COMPLICATIONS

- Infants hospitalized for RSV may be at increased risk for recurrent wheezing and reduced pulmonary function, particularly during the 1st decade of life.
- Overall mortality for infants and children <24 months of age is <1%.
- Although the relationship between RSV and asthma is unclear, RSV bronchiolitis in infancy has been linked to subsequent asthma.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- B97.4 Respiratory syncytial virus causing diseases classd elswhr
- J06.9 Acute upper respiratory infection, unspecified
- J21.0 Acute bronchiolitis due to respiratory syncytial virus

CLINICAL PEARLS

- RSV causes 50–90% of pediatric bronchiolitis.
- Hand sanitation (alcohol-based rubs are preferred) is the key to RSV prevention.
The diagnosis of RSV is typically clinical. Routine laboratory or radiology studies are not necessary.

Treatment of RSV is usually supportive.

Palivizumab should be used to prevent RSV in high-risk patients.
RESTLESS LEGS SYNDROME
Denise Sharon, MD, PhD, FAASM ● Rochelle Zak, MD

**BASICS**

**DESCRIPTION**
- Sensorimotor disorder consisting of a strong, nearly irresistible urge to move the limbs (1)[A].
- The urge usually affects the legs at least initially but may involve arms or other body parts (2)[C].
- The urge might be accompanied by uncomfortable and unpleasant sensations.
- The symptoms (Sx):
  - Begin or worsen during rest or inactivity
  - Are relieved by movement but recur with inactivity. If not present, previous relief by movement
  - Occur preferentially in the evening/night. If not present, previously reported circadian aspect
- Involuntary leg jerks reported during wake/sleep (1)[A].
- System(s) affected: nervous; musculoskeletal
- Early <45 years versus late >45 years onset (1)[A]
  - Early onset phenotype: 40–92% familial, stable, slow progression of Sx
  - Late onset phenotype: more aggravating factors; rapid progression is common.
- Synonym(s): Willis-Ekbom disease

**EPIDEMIOLOGY**

**Incidence**
- 0.8–2.2% annually
- Onset at any age
- Predominant sex: male = female (nulliparous)
- Parous females have twice the prevalence of males
- Temperature (cold weather, other environmental factors may increase incidence/trigger Sx.

**Prevalence**
- 4–15% in Caucasian adults, underdiagnosed
- 2–3% are clinically significant.
- 1–3% in children and adolescents
- Increases with age up to 70s
- Lower in non-Caucasians (except Koreans)

**Pregnancy Consideration**
- 10–30% prevalence; triggers/exacerbates RLS
- Predictors: past history (Hx), family Hx, iron deficiency (ID), Hgb ≤11 g/dL (3)[C]
- Peaks in 3rd trimester
- Most are relieved by 1-month postpartum.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Brain iron deficiency (BID) from either low serum iron or impaired transport of iron into the
brain, ID and associated conditions

- BID leads to central nervous system dopamine dysregulation:
  - Higher than normal dopamine levels in the morning and lower than normal dopamine at night leading to downregulation of dopamine D$_2$ receptors
  - Decreased dopamine transporter
- BID results in increased glutamate and decreased adenosine leading to hyperarousal and insomnia.
- Changes in substantia nigra, striatum, putamen: reduced iron, less myelin, fewer D$_2$ receptors
- Sensorimotor pathways: abnormalities and increased motor excitability
- Increased endogenous opioids, possibly
- Triggering and exacerbating factors:
  - Prolonged immobility, such hospitalizations
  - Medications (meds):
    - Most antidepressants (except bupropion)
    - Dopamine-blocking antiemetics (e.g., metoclopramide, prochlorperazine)
    - Phenothiazine antipsychotics (e.g., risperidone, clozapine, olanzapine quetiapine).
      Possible exception: aripiprazole (partial D$_2$ agonist)
    - Cognition-enhancing meds: memantine
    - Theophylline and other xanthines
    - Sedating antihistamines, OTC cold preparations

Genetics

Heterogeneous:
- Susceptibility loci: 2p14, 2q, 6p21.2, 9p, 12q, 14q, 15q23, and 20p
- Genes: MEIS1, MAP2K5/LBXCOR1, BTBD9, PRPRD, TOX3

RISK FACTORS

- ID: ferritin<75 ng/ml or Tsat<16
- Family Gx
- Increased with every pregnancy
- Chronic renal failure: 11–58% affects dialysis compliance
- Sleep deprivation (including untreated OSA)
- Alcohol, caffeine—limited data

GENERAL PREVENTION

- Regular physical activity/exercise during the day, low impact activity at night such as stretches, walks
- Adequate sleep; delay wake time if possible.
- Avoid caffeine, alcohol, nicotine mainly in the evening
- Avoid use of meds that may trigger RLS (4)[C].

COMMONLY ASSOCIATED CONDITIONS

- Insomnia, sleep walking, delayed sleep phase
- Iron deficiency, renal disease/uremia/dialysis, gastric surgery, IBS, liver disease (dis)
- Parkinson dis, multiple sclerosis, peripheral neuropathy, Machado-Joseph dis, migraine
- Anxiety, depression, ADHD
- Cardiovascular dis, coronary artery dis and stroke
Venous insufficiency/peripheral vascular dis  
Pulmonary hypertension, lung transplantation, chronic obstructive pulmonary dis (COPD)  
Orthopedic problems, arthritis, fibromyalgia  

**DIAGNOSIS**

- Clinical, based on Hx, “difficult to describe”
- All criteria must be met for RLS diagnosis (2)[C]:
  - An urge to move the legs, usually accompanied by or thought to be caused by uncomfortable and unpleasant sensations in the legs. The urge must:
    - Begin or worsen during periods of rest or inactivity such as lying down or sitting
    - Be partially or totally relieved by movement such as walking or stretching at least as long as the activity continues. Relief by movement may not be noticeable but must have been previously reported.
    - Occur exclusively or predominantly in the evening or night rather than during the day. Circadian aspect may not be noticeable but must have been previously reported.
  - The above features are not solely accounted for by “mimics” or another sleep, medical or behavioral condition. (Mimics include leg cramps, positional discomfort, habitual foot tapping, arthralgias/arthritis, myalgias, leg edema, peripheral neuropathy, and radiculopathy, even though some may coexist.)
  - The symptoms of RLS cause concern/distress; sleep disturbance; or impairment in mental, physical, social, occupational, educational, behavioral, or other area of functioning.

**HISTORY**

- Signs/symptoms (see also “Description”) (1)[A]
  - Painful in ~35% of patients
  - Example descriptions: antsy, burning, achy, itching, “can’t get comfortable”
  - Urge to move may be the only “discomfort.”
  - Some patients must get up and walk.
  - PLMS in ~80% of patients
  - Insomnia, fatigue, anxiety, depression
- Severity range: from rare, minor problem to daily, mild to moderate, to severe impact on quality of life

**Pediatric Consideration**

- Symptoms described in child’s own words
- Additional supportive findings (1),(2)[A]:
  - Insomnia or sleep disturbance
  - RLS in immediate biologic relative
  - PLMS

**Geriatric Considerations**

For diagnosis in the cognitively impaired:
- Rubbing or kneading the legs in the evening
- Evening hyperactivity (foot tapping, pacing, fidgeting, tossing/turning in bed)

**PHYSICAL EXAM**
Noncontributory, usually normal

DIFFERENTIAL DIAGNOSIS
- Vascular compression: single position change eliminates discomfort without requiring repetitive movements
- Claudication: movement doesn’t relieve pain
- Motor neuron disease fasciculation/tremor: no discomfort or circadian pattern
- Peripheral neuropathy: prominent daytime component unresponsive to dopamine agonists (DAs)
- Dermatitis/pruritus: movement only to scratch; no circadian pattern
- Sleep-related leg cramps: presence of muscle knot
- PLMD: no waketime urge to move
- Sleep starts: isolated involuntary events
- Rhythmic movement sleep disorder: movement periodicity faster than RLS
- Growing pains: no urge to move or relief by movement
- ADHD: no sleep complaints or disorders

DIAGNOSTIC TESTS & INTERPRETATION
Assessment of serum iron stores: ferritin, transferrin saturation, iron-binding capacity, serum iron (see also “General Measures”) (5)[C]

Diagnostic Procedures/Other
- Sleep study (PSG) helpful but not required
  - Frequent PLM during wake, prior to sleep and
  - Frequent PLMS on PSG support diagnosis
- Suggested immobilization test (SIT) or multiple SIT (m-SIT)
  - Conducted before or without nocturnal PSG
  - Patient attempts to sit still in bed for 1 hr (SIT) or four 1-hr periods, every 2 hrs (m-SIT)
    while completing every 10 min a visual analogue scale (VAS) or m-SIT disturbance scale.
  - SIT >40 movements per hour suggest RLS.

TREATMENT

GENERAL MEASURES
- If iron insufficient, supplement (4)[C]:
  - 325 mg FeSO₄ BID or QD with 100 mg Vit C
  - Repletion requires months until serum ferritin >75 ng/mL and Tsat >16%.
- Daily exercise; avoid activities that exacerbate RLS.
- Avoid exacerbating factors; maintain regular sleep.
- Treat obstructive sleep apnea (OSA) if present
- Hot baths, warm soaks, leg massage (6)[C]
- In bed: long socks, electric blanket, weighted blanket.
- Intense mental activity (games, puzzles, etc.)
- Consider not initiating medications in mild to moderate cases until general measures are applied.

MEDICATION
- Titrate to minimum dose necessary to control Sx, including sleep disturbance
- Assess Sx severity every encounter using a scale such as John Hopkins Restless Leg Severity Scale (JHRLSS), IRLS, sIRLS.
- Opt for longer-acting/extended-release options (4,5,6)[C].
- Refractory RLS may require combination therapy Tx.

**First Line**

- Anticonvulsants—less risk for augmentation and more effective in DA-naïve patients (4,5,6) [C]:
  - Gabapentin enacarbil (Horizant): 300–1,200 mg every day ~5:00 pm (4),(5)[C]
  - Pregabalin (Lyrica): 50–450 mg/day (off-label)
  - Gabapentin (Neurontin) 100–2,400 mg/day (off-label)
- Dopamine agonists (DA)—every encounter: assess for augmentation, impulse-control disorders (ICD) (4,5,6)[C]:
  - Pramipexole (Mirapex): 0.125–0.5 mg 1–2 hr before Sx; titrate by 0.125 mg q 4 days
  - Pramipexole ER 0.375 mg tablet
  - Ropinirole (Requip): 0.25–4.0 mg 05.–1 hr before Sx; titrate by 0.25 mg q 4 days
  - Ropinirole XL 2 mg
  - Transdermal rotigotine (Neupro): 1–3 mg/24 hr patch; start at 1 mg/d; titrate by 1 mg/wk.
- Avoid DAs in psychotic patients, particularly if taking dopamine antagonists.
- Add a different class of medication before exceeding DA-recommended dose.
- Iron if insufficient: ferrous sulfate 325 mg PO BID or qd + Vit C 100 mg (off-label)
- Ferric carboxymaltose 1,000 mg IV (off-label)

**Second Line**

- Off-label (4,5,6)[C]
- Opiates (tramadol-reported augmentation)
  - Methadone 5–20 mg evening/qhs
  - Oxycodone 5–40 mg evening/qhs
  - Buprenorphine naloxone 20/0.5 qd to bid
- Benzodiazepines and agonists: insomnia/anxiety
  - Clonazepam (Klonopin): 0.5–3.0 mg/day
  - Temazepam, triazolam, alprazolam, zaleplon, zolpidem, and diazepam
    - Short-acting DAs for occasional symptoms
      - Carbidopa/levodopa (Sinemet or Sinemet CR): 10/100 to 25/250; PRN up to 2/w

**Pregnancy Considerations**

- Initial approach: nonpharmacologic therapies, assess/correct ID
- Avoid medications class C or D.
- In 3rd trimester, if severe and failed above, may consider low-dose clonazepam, clonidine, carbidopa/levodopa or opioids (3)[B].

**Pediatric Considerations**

- First-line treatment: nonpharmacologic therapies, healthy sleep habits, assess/correct iron deficiency
- Consider low-dose, age adjusted gabapentin, clonidine, or clonazepam.

**Geriatric Considerations**
Avoid medications causing dizziness/unsteadiness.
Many medications trigger/worsen RLS in the elderly.

ISSUES FOR REFERRAL
- Severe, intractable symptoms
- Augmentation response to dopaminergic Tx
- Intractable iron deficiency

ADDITIONAL THERAPIES
- Vitamin, mineral suppl: Ca, Mg, B₁₂, folate
- Clonidine: 0.05 to 0.10 mg/day
- Baclofen: 20 to 80 mg/day

SURGERY/OTHER PROCEDURES
For orthopedic, neuropathic, or lower extremities vein disease (laser ablation, sclerotherapy)

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Pneumatic compression devices for the legs
- Relaxis leg vibration device (FDA-approved)
- Enhanced external counterpulsation
- Compression stockings
- Acupuncture, yoga
- MicroVas therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Prolonged hospitalization can trigger/worsen RLS.
- Addition of medications exacerbating RLS
- Withdrawal of medications treating RLS
- Control RLS Sx after orthopedic procedures.
- Changes in medical status may require meds changes (e.g., pramipexole contraindicated in renal failure, ropinirole contraindicated in liver dis).
- IV iron when oral iron fails/contraindicated
- When NPO, consider IV opiates or rotigotine
- Sleep interruption risks prolonged wakefulness.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- At 1-4-w intervals until stable and then annually
- If taking iron, reassess iron stores, at least ferritin.
- If status changes, assess for augmentation, ICD, associated conditions, and medications.

DIET
Avoid caffeine and alcohol, mainly in the evening.

PATIENT EDUCATION
PROGNOSIS
- Early onset: lifelong condition with no current cure
- Late onset/secondary: may subside with resolution of precipitating factors; otherwise chronic, progressive
- Current therapies usually control symptoms.

COMPLICATIONS
- Augmentation of symptoms following DA therapy to be assessed at every visit (5)[C]:
  - 4-hrs time advance of Sx or 2 to 4 hrs advance of Sx together with shorter latency at rest; Sx spread to other body parts or have greater intensity.
  - Higher doses increase risk, and increasing the dose makes Sx worse.
  - Greater risk with meds with shorter half-lives
  - Iron deficiency increases risk.
  - Down-titrate and discontinue DAs for at least 10 days; may add alternative medication then or to continue treatment
- The potential for ICD/Sx needs to be assessed at every visit in patients receiving DA (5)[C].
- Iatrogenic RLS (following blood loss or donation)

SEE ALSO
- Periodic Limb Movement Disorder (PLMD)
- International Restless Legs Syndrome Study Group: irlssg.org

CODES

ICD10
G25.81 Restless legs syndrome

CLINICAL PEARLS

- Insomnia is often a symptom of RLS.
- RLS is associated with depression, anxiety, ADHD.
- Antidepressants, antipsychotics, antiemetics, and sedating antihistamines can trigger or worsen RLS.
- Severity and change in Sx can be monitored using a severity scale such as sIRLS, IRLS, or JHRLSS.
- Iron supplement is an often well-tolerated, easily available treatment for RLS.
- Anticonvulsants (e.g., gabapentins) should be considered as initial therapy.
- To avoid augmentation, titrate DAs only up to the minimum dose necessary to control Sx.
- Patients on higher doses, shorter acting DA, and low ferritin are more prone to augmentation.
RETINAL DETACHMENT
Richard W. Allinson, MD ● Francis Allinson, MD

BASICS

DESCRIPTION
● Separation of the sensory retina from the underlying retinal pigment epithelium
● Rhegmatogenous retinal detachment (RRD): most common type; occurs when the fluid vitreous gains access to the subretinal space through a break in the retina (Greek rhegma, “rent”)
● Exudative or serous detachment: occurs in the absence of a retinal break, usually in association with inflammation or a tumor
● Traction detachment: Vitreoretinal adhesions mechanically pull the retina from the retinal pigment epithelium. The most common cause is proliferative diabetic retinopathy.
● System(s) affected: nervous

EPIDEMIOLOGY

Incidence
● Predominant age: Incidence increases with age.
● Predominant sex: male > female (3:2)
● Per year: 1/10,000 in patients who have not had cataract surgery

Prevalence
After cataract surgery, 1–3% of patients will develop a retinal detachment.

ETIOLOGY AND PATHOPHYSIOLOGY

● Traction from a posterior vitreous detachment (PVD) causes most retinal tears. With aging, vitreous gel liquefies, leading to separation of the vitreous from the retina. Vitreoschisis (lamellar separation of the posterior vitreous cortex) commonly precedes a complete PVD (1) [B]. The vitreous gel remains attached at the vitreous base, in the retinal periphery, resulting in vitreous traction that produces tears in the retinal periphery. There is an ~15% chance of developing a retinal tear from a PVD.
● PVD associated with vitreous hemorrhage has a high incidence of retinal tears.
● Exudative detachment
  – Tumors
  – Inflammatory diseases (Vogt-Koyanagi-Harada disease, systemic lupus erythematosus, posterior scleritis, sympathetic ophthalmia)
  – Miscellaneous (central serous retinopathy, uveal effusion syndrome, malignant hypertension, drugs—ipilimumab, topiramate)
● Traction detachment
  – Proliferative diabetic retinopathy
  – Cicatricial retinopathy of prematurity
  – Proliferative sickle-cell retinopathy
● Penetrating trauma

Genetics
Most cases are sporadic.
There is an increased risk of RRD if a sibling has been affected by this condition. The risk increases with higher levels of myopia in the family history.

RISK FACTORS
- Myopia (>5 diopters)
- Aphakia or pseudophakia
  - In patients undergoing small-incision coaxial phacoemulsification with high myopia (axial length ≥26 mm), the incidence of retinal detachment is 2.7%.
- PVD and associated conditions (e.g., aphakia, inflammatory disease, and trauma)
- Trauma
- Retinal detachment in fellow eye
- Lattice degeneration: a vitreoretinal abnormality found in 6–10% of the general population
- Glaucoma: 4–7% of patients with retinal detachment have chronic open-angle glaucoma.
- Vitreoretinal tufts: Peripheral retinal tufts are caused by focal areas of vitreous traction.
- Meridional folds: Redundant retina usually is found in the supranasal quadrant.
- The risk of retinal detachment after intravitreal injection for age-related macular degeneration or retinal vein occlusion is low with a rate of approximately 1 in 7,500 injections (2)[B].

GENERAL PREVENTION
Patients at risk for retinal detachment should have regular ophthalmologic exams.

Geriatric Considerations
- PVD
- Cataract surgery

Pediatric Considerations
Usually associated with underlying vitreoretinal disorders and/or retinopathy of prematurity

COMMONLY ASSOCIATED CONDITIONS
- Lattice degeneration
- High myopia
- Cataract surgery
- Glaucoma
- History of retinal detachment in the fellow eye
- Trauma

Pregnancy Considerations
Preeclampsia/eclampsia may be associated with exudative retinal detachment. No intervention is indicated, provided hypertension is controlled. Prognosis is usually good.

DIAGNOSIS

HISTORY
- Sudden flashes (photopsia)
- Shower of floaters
- Visual field loss: “curtain coming across vision”
- Central vision will be preserved if the macula is not detached.
- Poor visual acuity (20/200 or worse), with loss of central vision when macula is detached

**PHYSICAL EXAM**
- Elevation of the neurosensory retina from the underlying retinal pigment epithelium
- Elevation of retina associated with ≥1 retinal tears in RRD or elevation of the retina without tears in exudative detachment
- In 3–10% of patients with presumed RRD, no definite retinal break is found
- Tenting of the retina without retinal tears in traction detachment
- Pigmented cells within the vitreous (“tobacco dust”)

**DIFFERENTIAL DIAGNOSIS**
Retinoschisis (splitting of the retina)
- Vitreous cells and vitreous hemorrhage are found rarely in the vitreous with retinoschisis, whereas they are seen commonly in RRD.
- Retinoschisis usually has a smooth surface and is dome shaped, whereas RRD often has a corrugated, irregular surface.

**DIAGNOSTIC TESTS & INTERPRETATION**
Visual field testing: differentiates RRD from retinoschisis. An absolute scotoma is seen in retinoschisis, whereas RRD causes a relative scotoma.

**Initial Tests (lab, imaging)**
- Ultrasound (US) can demonstrate a detached retina and may be helpful when the retina cannot be visualized directly (e.g., with cataracts or vitreous hemorrhage).
- Fluorescein dye leakage can be seen in exudative retinal detachment; caused by central serous retinopathy and other inflammatory conditions
- Optical coherence tomography (OCT)

**TREATMENT**

**GENERAL MEASURES**
- Not all retinal tears or breaks need to be treated:
  - Flap or horseshoe tears in symptomatic patients (e.g., patients with flashes or floaters) are treated frequently.
  - Operculated holes in symptomatic patients are treated sometimes.
  - Atrophic holes in symptomatic patients are treated rarely.
- Lattice degeneration with or without holes within the lattice in an asymptomatic patient with prior retinal detachment in the fellow eye may be treated prophylactically.
- Flap retinal tears in asymptomatic patients frequently are treated prophylactically.
- Exudative detachments usually are managed by treating underlying disorder.
- Traction detachments usually are managed by observation. If the fovea is involved, a vitrectomy is needed.

**MEDICATION**

**First Line**
- Intraocular gases
  - Air
Perfluoropropane (C\(_3\)F\(_8\))
- Sulfur hexafluoride (SF\(_6\))
- Perfluorocarbon liquids
- Silicone oil
- Contraindications to intraocular gas: patients with poorly controlled glaucoma
- Precautions with intraocular gas: Expanding intraocular gas bubble increases intraocular pressure; therefore, avoid higher altitudes.
- Significant possible interactions with intraocular gas: Nitrous oxide used in general anesthesia can expand an intraocular gas bubble.

**Second Line**
Steroids may cause worsening of central serous retinopathy.

**SURGERY/OTHER PROCEDURES**
- **Timing of repairs**
  - Macula attached: within 24 hours if possible. If the detachment is peripheral and does not have features suggestive of rapid progression (e.g., large and/or superior tears), repair can be performed within a few days.
  - Preoperative posturing consisting of bed rest and positioning is frequently prescribed to patients with macula-on retinal detachment. Preoperative posturing can reduce the progression of macula-on retinal detachments (3)[B].
  - Macula recently detached: within 10 days of development of a macula-off retinal detachment (4)[B]
    - Old macular detachment: elective repair within 2 weeks
- If a retinal break has led to the development of a retinal detachment, surgery is needed. Surgical options (and combinations) include the following:
  - Demarcation laser treatment
  - Pneumatic retinopexy: Head positioning is required postoperatively.
  - Scleral buckle
  - Vitrectomy
  - Perfluorocarbon liquids, especially for giant tears (circumferential tears ≥90 degrees)
  - Silicone oil for complex repairs
- RRD may have >1 break. If any retinal break is not closed at the time of surgery, the surgery will fail.
- Additional surgery may be required if the retina redetaches secondary to a new retinal break or because of proliferative vitreoretinopathy (PVR).
- If a vitreous hemorrhage is present, presumably from a retinal tear and the fundus cannot be well visualized, consideration can be given for early vitrectomy (5)[C].
  - Patients who underwent pars plana vitrectomy (PPV) within the 1st week of presentation had a significantly lower risk of having a macula-off RD.
  - Both phakic and pseudophakic patients had a similar chance of developing a retinal detachment. Phakic patients who underwent PPV had a higher chance of requiring subsequent cataract surgery.
- There is a trend toward primary vitrectomy in the management of RRD. Eyes undergoing PPV for primary RRD repair may not need the addition of a scleral buckle.
- There is no statistical difference in the primary reattachment rate between eyes treated with PPV and scleral buckle for RRD in both phakic and pseudophakic/aphakic eyes.
Patients with RRD who are at high risk for PVR (retinal detachment in two or more quadrants, retinal tears >1 clock hour, preoperative PVR, or vitreous hemorrhage), PPV + scleral buckle was associated with higher rates of anatomical success compared to PPV alone (6)[B].

There is a reduced incidence of intraoperative retinal tear formation using a transconjunctival cannulated PPV system compared to the standard 20-gauge system requiring suture closure.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Recognition of condition is key (see “Diagnosis”).
- Refer to an ophthalmologist for exam and treatment, if indicated.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Bed rest prior to surgery in macula-on cases.
- Postoperatively, if intraocular gas has been used, the patient may need specific head positioning and should not travel to high altitudes to avoid expanding the intraocular gas bubble.

Patient Monitoring

- Alert ophthalmologist if there is new onset of floaters or flashes, increase in floaters or flashes, sudden shower of floaters, curtain or shadow in the peripheral visual field, or reduced vision.
- Patients with acute symptomatic PVD should be reexamined by the ophthalmologist in 3 to 4 weeks. The development of a retinal detachment is unlikely if no retinal tears are present on reexamination in 3 to 4 weeks.
- If acute symptomatic PVD is associated with gross vitreous hemorrhage that interferes with complete visualization of the retinal periphery by indirect ophthalmoscopy, the patient should be reexamined at short intervals with indirect ophthalmoscopy until the entire retinal periphery can be observed. Early PPV can be considered.
- If the examiner is not certain whether the retina is detached in the presence of opaque medium, US should be performed.

DIET

NPO if surgery is imminent

PATIENT EDUCATION

American Academy of Ophthalmology, 655 E. Beach Street, San Francisco, CA 94109-1336

PROGNOSIS

- RRD
  - 90% of retinal detachments can be reattached successfully after 1 or more surgical procedures. Postoperative visual acuity depends primarily on the status of the macula preoperatively. Also important is the length of time between the detachment and the repair (75% of eyes with macular detachments of <1 week will obtain a final visual acuity of 20/70 or better).
  - 87% of eyes with a retinal detachment not involving the macula attain a visual acuity of 20/50 or better postoperatively. 37% of eyes with a detached macula preoperatively attain 20/50 or better vision postoperatively.
– In 10–15% of successfully repaired retinal detachments not involving the macula preoperatively, visual acuity does not return to the preoperative level. This decrease is secondary to complications such as macular edema and macular pucker.
– Failed primary pneumatic retinopexy selects for RDs that are inherently more difficult to reattach.

- Risk factors associated with primary RRD repair failure include choroidal detachment, significant hypotony, grade C-1 PVR or worse, four detached quadrants, and large or giant retinal breaks. Additional risk factors associated with primary RRD repair failure include increased number of breaks and inferior location of retinal breaks.
- Tractional retinal detachment
  – When not involving the fovea, the patient usually can be observed because it is uncommon for these to extend into the fovea.
- Exudative retinal detachment
  – Management is usually nonsurgical.
  – The presence of shifting fluid is highly suggestive of an exudative retinal detachment. Fixed retinal folds, which are indicative of PVR, are seen rarely in exudative retinal detachment. If the underlying condition is treated, the prognosis generally is good.

**COMPLICATIONS**

- PVR is the most common cause of failed retinal detachment repair; 10–15% of retinas that reattach initially after retinal surgery will redetach subsequently, usually within 6 weeks, as a result of cellular proliferation and contraction on the retinal surface.
- Partial or total loss of vision due to macular detachment and/or PVR
- Moderate to severe forms of PVR usually are treated with PPV and fluid–gas exchange. If a segmental scleral buckle was placed at the initial procedure, it may need to be revised.
- Primary retinectomy can be used in cases of PVR without a scleral buckle.
- Scleral buckles may erode the overlying conjunctiva and lead to an infection.
- Optic neuropathy after PPV for macula-sparing primary RRD

Retinopathy, Diabetic

CODES

ICD10
- H33.001 Unspecified retinal detachment with retinal break, right eye
- H33.019 Retinal detachment with single break, unspecified eye
- H33.20 Serous retinal detachment, unspecified eye

CLINICAL PEARLS
- If a patient complains of the new onset of floaters or flashes of light, the patient should undergo a dilated eye exam to rule out a retinal tear or retinal detachment.
- There is an increased risk of retinal detachment after cataract surgery.
RETINOPATHY, DIABETIC
Richard W. Allinson, MD ● Francis Allinson, MD

BASICS

DESCRIPTION
- Noninflammatory retinal disorder characterized by retinal capillary closure and microaneurysms. Retinal ischemia leads to release of a vasoproliferative factor, stimulating neovascularization (NV) on retina, optic nerve, or iris.
- Most patients with diabetes mellitus (DM) will develop diabetic retinopathy (DR). It is the leading cause of new cases of legal blindness among residents in the United States between the ages of 20 and 64 years.
- DR can be divided into three stages.
  - Nonproliferative (background)
  - Severe nonproliferative (preproliferative)
  - Proliferative

Pregnancy Considerations
- Pregnancy can exacerbate condition.
- Pregnant diabetic women should be examined in 1st trimester and then every 3 months until delivery.

EPIDEMIOLOGY

Incidence
- Peak incidence of type 1, juvenile-onset DM is between the ages of 12 and 15 years. In type 1 DM (T1DM), there is β-cell destruction, leading to insulin deficiency.
- Peak incidence of type 2, adult-onset DM is between the ages of 50 and 70 years. Type 2 DM (T2DM) ranges from a condition characterized by insulin resistance with relative insulin deficiency to one that is predominantly an insulin secretory defect with insulin resistance.
- Incidence of DR is directly related to the duration of diabetes.
- <10 years of age, it is unusual to see DR, regardless of DM duration.

Prevalence
- 6.6% of the U.S. population between ages 20 and 74 years has DM.
- ~25% of the diabetic population has some form of DR.
- Predominant age
  - Risk increases after puberty.
  - 2/3 of juvenile-onset diabetics who have had DM for at least 35 years will develop proliferative DR (PDR), and 1/3 will develop macular edema. Proportions are reversed for adult-onset diabetes.
- Predominant sex: male = female (type 1, juvenile-onset DM); female > male (type 2)

ETIOLOGY AND PATHOPHYSIOLOGY
- Related to development of diabetic microaneurysms and microvascular abnormalities
- Reduction in perifoveal capillary blood flow velocity, perifoveal capillary occlusion, and increased retinal thickness at the central fovea in diabetic patients are associated with visual
impairment in patients with diabetic macular edema (DME).

- Vascular endothelial growth factor (VEGF) is elevated in patients with hypoxic retina. Intraocular levels of VEGF are elevated in patients with retinal or iris NV. Retinal hypoxia also contributes to DME, and VEGF is a major contributor to DME.

**RISK FACTORS**
- Duration of DM (usually >10 years)
- Poor glycemic control
- Pregnancy
- Renal disease
- Systemic hypertension (HTN)
- Smoking
- Elevated lipid levels
- Myopic eyes (eyes with longer axial length) have a lower risk of DR.

**GENERAL PREVENTION**
- Monitor and control of blood glucose.
- Schedule yearly ophthalmologic eye exams.

**COMMONLY ASSOCIATED CONDITIONS**
- Glaucoma
- Cataracts
- Retinal detachment
- Vitreous hemorrhage (VH)
- Disc edema (diabetic papillopathy); may occur in T1DM and T2DM

**DIAGNOSIS**

**PHYSICAL EXAM**
- Eye exam: measurement of visual acuity and documentation of the status of the iris, lens, vitreous, and fundus
- Nonproliferative (background) DR
  - Microaneurysms
  - Intraretinal hemorrhage
  - Macular edema causing decrease in central vision
  - Lipid deposits
- Severe nonproliferative (preproliferative) DR
  - Nerve fiber layer infarctions (“cotton wool spots”)
  - Venous beading
  - Venous dilatation
  - Intraretinal microvascular abnormalities (IRMA)
  - Extensive retinal hemorrhage
- The Early Treatment Diabetic Retinopathy Study (ETDRS) developed the 4:2:1 rule for severe nonproliferative diabetic retinopathy (NPDR). Severe NPDR was defined as having any one of the following features:
  - Severe intraretinal hemorrhages and microaneurysms in four quadrants
  - Venous beading in two or more quadrants
IRMAs in one or more quadrants

- Proliferative Diabetic Retinopathy (PDR)
  - New blood vessel proliferation: NV on the retinal surface, optic nerve, and iris
  - Visual loss caused by VH, traction retinal detachment. NV can result in contraction of fibrovascular tissue on a vitreous scaffold, which can lead to VH and traction retinal detachment.

**DIFFERENTIAL DIAGNOSIS**

Other causes of retinopathy (e.g., radiation, retinal venous obstruction, HTN)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**

- Fluorescein angiography demonstrates retinal nonperfusion, retinal leakage, and PDR.
- Optical coherence tomography (OCT) can be used to help detect DME by measuring retinal thickness.
- Optical coherence tomography angiography (OCTA)

**TREATMENT**

**GENERAL MEASURES**

- The Diabetes Control and Complications Trial (DCCT) recommended that for most patients with insulin-dependent DM, blood glucose levels should be as close to the nondiabetic range as is safe to reduce the risk and rate of progression of DR.
  - In the DCCT, insulin-dependent DM patients were randomly assigned into either conventional or intensive insulin treatment. The DCCT demonstrated that intensive insulin therapy reduced the risk of DME and retinal NV. The benefit of intensive insulin therapy with the reduced risk of DR-associated microvascular complications persists for at least 10 years.
  - In the DCCT, intensive insulin therapy was more effective in reducing the risk of progression of DR in the less advanced stages. However, advanced DR also benefited from the intensive insulin therapy.
- Microvascular complications, including PDR, are increased when blood sugar levels are ≥200 mg/dL.
- Cataracts are more common among those with DM. Try to delay cataract surgery in DM patients with retinopathy until the symptoms are more severe. Cataract surgery can cause retinopathy to worsen and increase the risk for development of DME.
- HTN has a detrimental effect on DR and must be controlled.

**MEDICATION**

- Treatment with the angiotensin-receptor blocker candesartan, used to treat HTN, has been shown to result in regression of DR in some patients.
- Statin therapy in patients with T2DM is associated with a decreased risk of DR.
  - T2DM patients on lipid-lowering medications are less likely to develop NPDR, PDR, or DME (1)[A].
- Aspirin
  - Does not alter progression of DR
– Does not increase the risk of VH

**SURGERY/OTHER PROCEDURES**

- **Treatment for DME**
  - Intravitreal anti-VEGF is first-line treatment for DME:
    - Ranibizumab, an antibody fragment that binds VEGF, can be used to treat DME when injected intravitreally. Ranibizumab 0.3 mg (0.05 mL) injected intravitreally monthly resulted in improved vision and reduced central foveal thickness.
    - Anti-VEGF treatment results in superior clinical outcomes compared to laser photocoagulation for DME.
    - Intravitreal ranibizumab injections (IRIs) are beneficial for patients with DME and concurrent macular nonperfusion.
    - IRI for DME may also improve DR severity and reduce the risk of DR progression.
    - Treat and extend dosing for IRI decreased the number of injections while giving similar visual and anatomic outcomes compared with monthly dosing at 1 year.
    - As-needed treatment after a loading dose of 3 monthly injections has been shown to result in comparable results to more frequent treatments.
  - Bevacizumab, a full-length antibody that binds VEGF, can be used to treat DME when injected intravitreally. This is an off-label use.
  - Aflibercept, a decoy receptor for VEGF that inhibits all isoforms of VEGF-A and placental growth factor. Aflibercept 2 mg (0.05 mL) injected intravitreally every 4 weeks for the first 5 injections followed by 2 mg (0.05 mL) intravitreally once every 8 weeks. It is indicated for patients with DME and for DR in patients without DME.
    - Intravitreal aflibercept injection (IAI) has demonstrated significant superiority in functional and anatomic end points over macular laser photocoagulation.
    - At worse levels of initial visual acuity (20/50 or worse) in patients with DME, IAI was more effective in improving vision than ranibizumab or bevacizumab with 1-year follow-up. When the initial vision loss was mild (20/32 to 20/40) in patients with DME, there was no significant difference between aflibercept, ranibizumab, and bevacizumab.
      - Aflibercept had superior 2-year visual acuity outcomes compared with bevacizumab. The superiority of aflibercept over ranibizumab, noted at 1 year, was no longer seen at 2 years of follow-up (2)[A].
      - Among eyes with center-involved DME (CI-DME) and good visual acuity (20/25 or better), there was no significant difference in vision loss at 2 years whether eyes were initially managed with IAI or with laser treatment or observation and were given IAI only if visual acuity worsened. Observation without treatment unless visual acuity worsens may be a reasonable plan of action for CI-DME (3)[A].
      - As-needed IAI has been shown to maintain vision and reduce treatment frequency.
  - Faricimab inhibits both Angiopoietin-2 and VEGF-A. It is being investigated for the treatment of DME (4)[A].
    - Topical povidone-iodine prophylaxis is important to help prevent endophthalmitis from intravitreous injections from anti-VEGF treatment.
    - Focal laser treatment.
    - Vitrectomy may benefit some with diffuse macular edema. This may apply especially to eyes with vitreomacular traction found on OCT and with persistent DME.
    - Intravitreal triamcinolone may be used for DM-related macular edema that fails laser
- Treatment; no long-term benefit of intravitreal triamcinolone relative to focal/grid photocoagulation in patients with DME
- Intraocular steroid implants for DME. Either a dexamethasone implant or a fluocinolone acetonide implant. Complications of these implants include cataract and glaucoma.

- Treatment for PDR:
  - Thermal laser photocoagulation in a panretinal pattern is a common form of treatment for PDR. The goal of panretinal photocoagulation (PRP) is regression or involution of NV. PRP destroys ischemic retina and decreases the neovascular stimulus.
  - The Diabetic Retinopathy Study demonstrated that when PRP was used to treat PDR or severe NPDR, eyes treated with PRP had a reduction of 50% or more in the rates of severe vision loss compared with untreated control eyes. In certain subgroups, the incidence of severe visual loss in untreated eyes was as high as 36.9% at 2 years.
  - Patients with DME and high-risk proliferative disease can have simultaneous focal and PRP without adversely affecting the visual outcome.
  - IRI is an alternative therapy to PRP for PDR, and both PRP and IRI are viable treatment options for patients with PDR (5)[B].
  - Treatment with IRI plus PRP may be more effective than PRP monotherapy for NV regression in patients with high-risk PDR (6)[B].
  - IAI can also be used to treat PDR.
  - Intravitreal bevacizumab injection (IBI) may be of benefit in the treatment of VH due to PDR and may help to avoid the need for a pars plana vitrectomy (PPV). This is an off-label use.
  - PPV recommended for patients with severe PDR, traction retinal detachment involving the macula, and nonclearing VH
  - The Diabetic Retinopathy Vitrectomy Study (DRVS) demonstrated the benefits of early PPV (1 to 6 months after onset of VH) in T1DM and for eyes with very severe PDR.
  - Immediate PPV with endolaser may be considered for PDR-associated VH (<30 days).
  - Preoperative IBI can be used as an adjuvant to vitrectomy for complications of PDR. This is an off-label use.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Nutritional antioxidant intake of vitamins C and E and of β-carotene has no protective effect on DR.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Scheduled ophthalmologic eye exams
- Yearly follow-up if no retinopathy
- Every 6 months with background DR
- At least every 3 to 4 months with pre-PDR
- Every 2 to 3 months with active PDR
- Patients with DME should be followed every 4 to 6 weeks.

DIET
In middle-age and older individuals with T2DM, intake of at least 500 mg/day of dietary long-chain omega-3 polyunsaturated fatty acids, achievable with 2 weekly servings of oily fish, is associated with a decreased risk of visual loss from DR.

PATIENT EDUCATION
- Advise regular ophthalmic exams.
- Stress importance of glucose control through diet, exercise, drugs/insulin.

PROGNOSIS
If the condition is diagnosed and treated early in development, outlook is good. If treatment is delayed, blindness may result.

COMPLICATIONS
- Repeated intravitreal injection of anti-VEGF therapy may increase the risk of sustained intraocular pressure elevation and the possible need for ocular hypotensive treatment.
- Blindness

ADDITIONAL READING
CODES
ICD10
- E11.319 Type 2 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E10.319 Type 1 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E10.329 Type 1 diab w mild nonprlf diabetic rtnop w/o macular edema

CLINICAL PEARLS
- Schedule yearly ophthalmologic eye exams.
- Options for the treatment of diabetic macular edema include focal laser treatment, intravitreal triamcinolone, intravitreal ranibizumab, intravitreal bevacizumab, intravitreal aflibercept, intraocular steroid implants, and vitrectomy.
RH INCOMPATIBILITY
Jennifer G. Chang, MD

**BASICS**

**DESCRIPTION**
- Antibody-mediated destruction of red blood cells (RBCs) that bear Rh-surface antigens in individuals who lack the antigens and have become isoimmunized (sensitized) to them
- System(s) affected: hematologic/lymphatic/immunologic
- Synonym(s): Rh isoimmunization; Rh alloimmunization; Rh sensitization

**EPIDEMIOLOGY**

**Incidence**
- Predominantly affects fetuses/neonates of isoimmunized, childbearing females; varies by race and ethnicity
- ~15% of the white population and smaller fractions of other races are Rh-negative and susceptible to sensitization.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Circulating antibodies to Rh antigens (transplacentally transferred antibodies in the case of a fetus/newborn) attach to Rh antigens on RBCs
- Immune-mediated destruction of RBCs leads to hemolysis, anemia, and increased bilirubin production.
- Transplacental fetomaternal hemorrhage during pregnancy or, more commonly, at delivery
- Most cases of alloimmunization involve small volume fetomaternal hemorrhage (0.1 mL or less) and occur with uncomplicated vaginal delivery.
- Transfusion of Rh-positive blood to Rh-negative recipient; exposure to needles contaminated with Rh-positive blood
- Most commonly seen in the Rh-positive fetus of an Rh-negative mother (~10% of all pregnancies)

**Genetics**
- Complex autosomal inheritance of polypeptide Rh antigens; three genetic loci with closely related genes carry an assortment of alleles: Dd, Cc, and Ee.
- Individuals who express the D antigen (also called Rho or Rho[D]) are considered Rh positive. Individuals lacking the D antigen are Rh negative.
- Variant D alleles (weak D and partial D) are heterogeneous, altered forms of the D antigen. Some D variants are at risk of formation of anti-D antibodies, whereas others are not. With current blood typing procedures, certain D variants likely to produce alloimmunization are typed as D negative, although this does not include all genetic subtypes at risk of isoimmunization.
- Another variant D antigen, DEL, has been identified in some individuals (predominantly Asians). Those with partial DEL expression are at risk for alloimmunization and should be considered clinically Rh negative. Women with complete DEL are not likely to be sensitized by exposure to Rh-D antigens through pregnancy or transfusion and should be considered clinically Rh-positive and do not need RhD prophylaxis.
• Antibodies may be produced to C, c, D, E, or e in individuals lacking the specific antigen; only D is strongly immunogenic.
• Isoimmunization to Rh antigens in susceptible individuals is acquired, not inherited.

**RISK FACTORS**
• Any Rh-positive fetus in an Rh-negative pregnant woman can result in sensitization.
• Weak D and partial D women are a heterogeneous group. Although previously reported to be Rh positive and treated as such, alloimmunization has been reported and can result in HDFN or fatal hydrops fetalis.
• Native risk of isoimmunization after Rh-positive pregnancy had been estimated at ≤15% but seems to be decreasing.
• The risk of isoimmunization antepartum is only 1–2%.
• The risk of isoimmunization is 1–2% after spontaneous abortion and 4–5% after induced abortion. It is unclear what the risk is with early medication-induced abortion but is likely very low due to the small volume of embryonic red cells.
• Cesarean delivery, multifetal gestation, placenta previa or abruption, manual removal of the placenta may increase volume of fetomaternal hemorrhage.
• Use of Rho(D) immunoglobulin prophylaxis has reduced incidence of isoimmunization to <1% in susceptible pregnancies (1)[C].

**GENERAL PREVENTION**
• Blood typing (ABO and Rh) on all pregnant women and prior to blood transfusions
• Antibody screening early in pregnancy
• Rh immunoglobulin prevents only sensitization to the D antigen.
• Cell-free fetal (Cff) DNA testing with selective administration of Rh immunoglobulin when the fetus tests Rh positive has been shown to be as effective at preventing new Rh sensitization when compared to routine administration of Rh immunoglobulin to all Rh-negative women. Such an approach avoids unnecessary use of Rh immunoglobulin (2)[B].
• Currently, routine administration of Rh immune globulin is more cost-effective than use of Cff DNA testing in the United States (1)[C].
• For prophylaxis, Rho(D) immunoglobulin (RhIG, RhoGAM, HyperRHO, Rhophylac) given to unsensitized, Rh-negative women after the following:
  – Threatened miscarriage or miscarriage (controversial before 12 weeks’ gestation)
  – Therapeutic pregnancy termination (no evidence for or against prophylaxis before 6–7 weeks in medication-induced abortion)
  – Ectopic pregnancy
  – Evacuation of molar pregnancy
  – Intrauterine fetal death
  – Antepartum hemorrhage
  – Trauma to abdomen
  – Amniocentesis or cordocentesis
  – Chorionic villus sampling
  – External cephalic version
  – Within 72 hours of delivery of an Rh-positive infant
  – Given routinely at 28 weeks’ gestation
• Prophylaxis prevents sensitization that could affect a subsequent pregnancy and has little effect on the current pregnancy.
• Dose for prophylaxis
  – 50-μg (up to 120-μg) dose for events up to 12 weeks’ gestation
  – 300-μg dose for events after 12 weeks’ gestation
  – Higher doses may be required in the event of a large fetal–maternal hemorrhage (>30 mL of whole blood).

COMMONLY ASSOCIATED CONDITIONS
• Neonatal jaundice (common)
• Hemolytic disease of newborn (less common)
• Hydrops fetalis (rare)
• Kernicterus (rare)
• See “Erythroblastosis Fetalis” topic.

DIAGNOSIS

PHYSICAL EXAM
• Jaundice of newborn
• Kernicterus features (choreoathetoid movements, gaze abnormalities, dental enamel dysplasia)
• Fetal hydrops or fetal death in utero if severe (see “Erythroblastosis Fetalis” topic)

DIFFERENTIAL DIAGNOSIS
• ABO incompatibility
• Other blood group (non-Rh) isoimmunization
• Nonimmune fetal hydrops
• Hereditary spherocytosis
• RBC enzyme defects

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Positive indirect Coombs test (antibody screen) during pregnancy
• Paternal blood type; if unknown or heterozygous, amniocentesis for fetal antigen type using PCR is highly sensitive (98.7%) and specific (100%); current standard practice in U.S. (1)(C).
• Cell-free fetal DNA (Cff DNA) test: standard practice in many European countries; available in the United States but is not a widely covered benefit. It allows detection of fetal Rh genotype with accuracy of 97.1%, sensitivity of 97.2%, and specificity of 96.8%.
• Rosette test (qualitative detection of fetomaternal bleeding); if positive, perform Kleihauer-Betke test (fetal hemoglobin acid elution, Hb F slide elution) or flow cytometry (more sensitive but not widely available) to quantify an acute fetal–maternal bleed
• Assess degree of fetal anemia
• Blood type and direct Coombs test in newborn

Follow-Up Tests & Special Considerations
Prior administration of Rho(D) may lead to weakly (false-) positive anti-D (indirect Coombs test) in mother and direct Coombs test in infant.
TREATMENT

GENERAL MEASURES
- Depending on severity of involvement, treatment of fetus may include the following:
  - Intrauterine transfusion \[(3)\] \[(B)\], \[(4)\] \[(A)\]
  - Early delivery—typically no later than 37 to 38 weeks’ gestation \[(1)\] \[(C)\], \[(4)\] \[(A)\]
- Treatment of newborn may include the following:
  - Exchange transfusion
  - Transfusion after delivery
  - Phototherapy
- Inconclusive evidence on efficacy of intravenous immunoglobulin to reduce need for exchange transfusion \[(5)\] \[(A)\].

ISSUES FOR REFERRAL
Because of the specialized, somewhat hazardous treatment measures involved, pregnancies in Rh-sensitized women are usually managed at tertiary-care facilities with maternal–fetal medicine specialists.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Initial monitoring of the newborn as inpatient or in special care nursery if treatment interventions are needed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- In most cases, outpatient ambulatory management is appropriate during the antepartum period.
- Antibody titer measured monthly in isoimmunized women until 24 weeks and every 2 weeks thereafter during first affected pregnancy; a titer of \(\geq 1:16\) indicates the need for further testing \[(4)\] \[(A)\].
- If the patient had a previously affected infant, an Rh-positive fetus in the current pregnancy should be considered at risk regardless of antibody titers \[(4)\] \[(A)\].
  - Fetal heart rate testing/US to assess fetal status
  - Doppler US measurement of cerebral blood flow (should be performed only by adequately trained providers). If peak middle cerebral artery (MCA) systolic velocity >1.5 multiples of the median for gestational age, further testing is needed (cordocentesis) for diagnosing fetal anemia \[(4)\] \[(A)\].
  - Umbilical blood sampling (cordocentesis) for fetal blood type, hematocrit, reticulocyte count, and presence of erythroblasts \[(4)\] \[(A)\]
  - Amniocentesis for amniotic fluid bilirubin levels \[(4)\] \[(A)\]
  - Amniocentesis for fetal lung maturity if early delivery is a treatment option \[(1)\] \[(C)\], \[(4)\] \[(A)\].

PROGNOSIS
- With appropriate monitoring and treatment, infants born of severely affected pregnancies have a survival rate of \(>80\%\) \[(4)\] \[(A)\].
Even with severe disease, the neurologic outcome of survivors is generally good. Fetus with hydrops have a higher mortality rate and higher risk of neurologic impairment. Disease is likely to be more severe in affected subsequent pregnancies.

**COMPLICATIONS**
- Pregnancy loss from umbilical blood sampling
- Pregnancy loss from intrauterine transfusion
- Fetal distress requiring emergent delivery

CODES

ICD10
- P55.0 Rh isoimmunization of newborn
- O36.0990 Maternal care for other rhesus isoimmunization, unspecified trimester, not applicable or unspecified
- T80.40XA Rh incompat react due to tranfs of bld/bld prod, unp, init

CLINICAL PEARLS

- If paternity is certain, determining that the father does not carry the Rh(D) blood group antigen eliminates the need to give RhIG prophylaxis during pregnancy or the need for special fetal surveillance if the mother is already sensitized.
- The dose of RhIG for prophylaxis is affected by gestational age. The fetal blood volume is only a few milliliters at 12 weeks’ gestation. Therefore, a 50-μg dose of RhIG may be used for threatened, spontaneous, or induced abortions up to 12 weeks’ gestation, instead of the standard 300-μg dose.
- Diagnosis is made by antibody titer. Affected pregnancies will require maternal–fetal medicine consultations and monitoring of antibody levels; if titer >1:16, will also require serial monitoring of MCA peak velocity. This will determine the need for invasive testing and transfusions.
- If the patient had a previously affected infant, an Rh-positive fetus in the current pregnancy should be considered at risk regardless of antibody titers—proceed to MCA peak velocity monitoring.
- The current standard in the United States is to provide prophylaxis to all unsensitized Rh-negative mothers; however, determination of the fetal Rh status by Cff DNA testing is reliable and could allow for targeted, rather than universal prophylaxis. Currently routine prophylaxis is more cost-effective in the United States.
RHABDOMYOLYSIS
Caroline Tschibelu, MD • Chirag N. Shah, MD, FACEP

BASICS

DESCRIPTION
- Breakdown of skeletal muscle with systemic release of intracellular contents
- Rhabdomyolysis typically presents with muscle pain, weakness, and reddish brown (tea-colored) urine. Up to 50% of patients are asymptomatic.

EPIDEMIOLOGY

Incidence
26,000 hospitalizations annually in United States

ETIOLOGY AND PATHOPHYSIOLOGY

Risk factors
- Direct muscle trauma (most common cause)
  - Crush injuries
  - Extended periods of muscle pressure (during surgery, unconscious from alcohol ingestion)
  - Burns, electrocution, lightning strike
- Muscle exertion
  - Intense and/or prolonged physical exercise (marathon runners, athletes, contact sports)
  - Seizures
  - Delirium tremens
- Drugs and toxins
  - Alcohol
  - Cocaine (most common recreational drug), methamphetamine, phencyclidine, heroin, bath salts (1)[B], synthetic marijuana has been associated with severe rhabdomyolysis (2)[A].
  - Antipsychotics (due to neuroleptic malignant syndrome, malignant hyperthermia, and dystonia)
  - Zidovudine
  - Antimalarials
  - HMG-CoA reductase inhibitors (statins) (risk <0.01%—elevated with higher doses and in combination with fibrates)
  - Colchicine
  - Corticosteroids
  - Carbon monoxide
  - Snake envenomation
- Muscle ischemia
  - Thrombosis, embolism, sickle cell disease
  - Compartment syndrome
  - Tourniquets
- Infections
  - Viral: influenza A and B, coxsackievirus, HIV, varicella
  - Bacterial: Streptococcus or Staphylococcus sepsis, gas gangrene, necrotizing fasciitis,
Salmonella, Legionella
- Malaria
- Hypothermia
- Hyperthermia
- Autoimmune disorders
  - Polymyositis, dermatomyositis
- Metabolic and endocrinologic:
  - Hypothyroidism or thyrotoxicosis
  - Electrolyte imbalances (e.g., hyponatremia, hypernatremia, hypokalemia, hypocalcemia, hypophosphatemia)
  - Diabetic ketoacidosis
  - Hyperosmolar state

**Genetics**
Hereditary causes of rhabdomyolysis are rare but should be suspected in children, patients with recurrent attacks, or patients who have attacks after minimal exertion, mild illness, or starvation.
- Genetic disorders (2)[C]
  - Muscular dystrophies
  - Disorders of lipid metabolism (e.g., carnitine palmitoyltransferase deficiency)
  - Disorders of carbohydrate metabolism (i.e., phosphofructokinase deficiency, phosphoglycerate mutase, myophosphorylase deficiency, a.k.a. McArdle disease/deficiency)
  - Glycogen storage diseases (e.g., phosphorylase B kinase deficiency) and others (e.g., lactate dehydrogenase A deficiency)
  - Mitochondrial disorders

**GENERAL PREVENTION**
- Avoid excessive exertion; ensure adequate hydration.
- Avoid precipitating drugs, metabolic and electrolyte abnormalities.

**DIAGNOSIS**

**HISTORY**
- Crush injury: direct trauma, prolonged compression/immobility. Causes include motor vehicle accidents (MVA) and entrapment in collapsed buildings. The elderly are more susceptible to crush injury due to immobility and falls. Rhabdomyolysis usually occurs after 1 hour of immobilization, but cases reported with compression lasting <20 minutes.
- Possible history of overexertion or use of drug/toxin (e.g., cocaine, amphetamine, statins), particularly in warm environments
- Patient may complain of fever, malaise, muscle aches, weakness, cramps, or fatigue.
- Nausea, vomiting, diarrhea
- Dark urine
- Agitation while patients are in restraints
- Prolonged periods of lying on a hard surface (e.g., intoxicated or obtunded individuals)

**PHYSICAL EXAM**
- Vital signs—temperature, pulse, respirations, blood pressure, and oxygenation status
May have obvious muscle tenderness, evidence of crush injury, weakness and/or swelling on exam. The muscle exam may also be completely normal.

- Tea-colored urine is indicative of myoglobinuria.
- Decreased urine output may indicate renal failure.

DIFFERENTIAL DIAGNOSIS
- Any disease that causes acute tubular necrosis may be confused with rhabdomyolysis.
- Inflammatory myopathies
- Infection (bacterial or viral)
- Phosphorylase, phosphofructokinase, carnitine palmityl transferase, phosphoglycerate mutase deficiency
- Guillain-Barré syndrome
- Myocardial infarction

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Creatine kinase (CK) is the most important diagnostic test: Elevated >5 times the upper limit of normal or >1,000 U/L. CK levels >5,000 U/L are causally related to acute renal failure (ARF) and should prompt aggressive fluid resuscitation.
- CK levels peak at ~24 hours and return to normal after 3 to 5 days, making CK a more sensitive marker than myoglobin. Myoglobin is responsible for renal damage.
- Serum myoglobin levels peak within a few hours and return to normal after ~24 hours. Normal myoglobin levels do not rule out rhabdomyolysis (due to rapid clearance).
- Urinalysis: Dipstick test positive for blood without erythrocytes in sediment suggests injury from either hemoglobin or myoglobin.
- Elevations of serum potassium from muscle injury can be compounded by ARF.
- Initial hypocalcemia: Calcium enters the injured muscle cells and precipitates as calcium phosphate, leading to calcification of ischemic muscle cells. Only correct initial hypocalcemia if patient is symptomatic or has ECG changes; resolves during the renal recovery phase.
- Hypercalcemia during renal recovery phase: unique to rhabdomyolysis-induced ARF for 20–30% of patients. As renal function improves, there is mobilization of the precipitated calcium, increase in calcitriol, and hyperphosphatemia resolves.
- Extreme hyperuricemia may be present and can cause acute uric acid nephropathy.
- Elevations in BUN and creatinine suggest ARF.
- Reversible hepatic dysfunction can occur. However, elevations in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactic dehydrogenase may be due to muscle injury rather than hepatic injury.
- Disseminated intravascular coagulation (DIC) suggested by increase in coagulation times, fibrin degradation products, and D-dimer with decreases in platelets and fibrinogen.
- 12-lead ECG because hyperkalemia can induce fatal arrhythmias.

Follow-Up Tests & Special Considerations
- Delayed renal failure/electrolyte abnormalities despite normal initial levels
- Ongoing muscle injury is manifested by rising creatine phosphokinase (CPK).
- Renal imaging shows findings similar to other mechanisms of ARF.

Diagnostic Procedures/Other
Muscle compartment pressures if compartment syndrome is suspected

**Test Interpretation**
- Muscle necrosis
- Myoglobin-related renal injury may resemble acute tubular necrosis from other causes.

**TREATMENT**

**GENERAL MEASURES**
- Address underlying cause (e.g., medications cessation, temperature control, trauma, infection).
- Aggressive hydration is often necessary. With severe muscle trauma (crush injuries), up to 12 L of fluid may be sequestered in the muscles.
- Monitor CK levels, renal function, and electrolytes.
- Follow potassium levels due to potential for arrhythmias.
- Treat DIC or hepatic dysfunction appropriately.
- Recognize and treat compartment syndrome promptly.

**MEDICATION**

**First Line**
- Aggressive fluid resuscitation is the most important intervention: normal saline (NS) and 5% glucose solution with a target urine output of 200 to 300 mL/hr. Alternating NS and 5% glucose is recommended to prevent volume overload. Infusion rate should be 500 mL/hr (5)[C],(6)[A].
- Alkalization of the urine may decrease myoglobin-induced nephrotoxicity in the tubules (sodium bicarbonate to increase urine pH >6.5):
  - Use is controversial.
  - Side effects include worsening hypocalcemia.
  - Sodium bicarbonate may be of use in patients with very high CK levels, acidosis, or coexisting hyperkalemia.
  - Place 150 mEq (3 ampules) NaHCO₃ in 1 L of D5W and infuse at 200 mL/hr.

**Second Line**
- IV mannitol as a bolus if urine output remains low, 1 to 2 g/kg, not to exceed 200 g in 24 hours with a cumulative dose of 800 g. It is used to prevent ARF only if diuresis is not adequate (<200 mL/hr) despite fluid therapy (6)[A].
  - Increases prostaglandin production leading to renal vasodilation and diuresis, reducing susceptibility to myoglobin injury. As an osmotic agent, filtered but not reabsorbed by the tubules, mannitol increases sodium delivery and diuresis. This may remove necrotic cell debris and prevent rise in compartment pressures.
  - Use of mannitol is controversial. No good evidence that it improves outcomes more than aggressive IV hydration. As a free-radical scavenger, mannitol has renal protective effects if used before tubular occlusion.
  - Consider adding furosemide to force diuresis if necessary (40 to 120 mg/day).
  - Do not diurese in anuric renal failure; caution also in the elderly and patients with heart disease.
- Hyperkalemia can result from massive release of intracellular potassium stores or ARF. Severe
hyperkalemia may be life-threatening. Treatment when ECG changes are present (tall, thin T waves; PR prolongation; QRS widening; P wave flattening).

- Calcium gluconate: to stabilize the cardiac membrane. IV 1 to 2 ampules (0.5 mL 10% calcium gluconate = 4 mg elemental calcium; give 4 mg/kg/hr for 4 hours.)
- If acidosis is present: 1 to 2 ampules (2 to 3 mL/kg) sodium bicarbonate IV. Sodium bicarbonate can worsen hypocalcemia.
- If tolerated: Oral sodium polystyrene sulfonate (Kayexalate) as much as 20 g (1 g/kg) can be given via enema.
- Insulin and albuterol transiently drive potassium into the cells. Administration of glucose can prevent the hypoglycemic effects of insulin.
- Precautions: continuous monitoring of potassium levels to prevent overcorrecting with potential hypokalemia and arrhythmias
- Indications for dialysis include resistant and symptomatic hyperkalemia (ECG), oliguria (<0.5 mL/kg over 12-hour period), anuria, volume overload, or persistent acidosis (pH <7.1).

ISSUES FOR REFERRAL
- Usually managed as an inpatient
- Diagnosis of compartment syndrome merits surgical consultation for consideration of fasciotomy.
- Renal dialysis may be indicated in ARF.

ADDITIONAL THERAPIES
During the oliguric phase, symptomatic hypocalcemia (rare) may benefit from IV calcium gluconate.

SURGERY/OTHER PROCEDURES
For muscle entrapment/compartment syndrome

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Patients with significant elevations of CK should be admitted for IV hydration and clinical monitoring.
- Volume expansion with NS to increase urine output to at least 150 mL/hr
- CK usually peaks 24 to 36 hours after muscle injury, so monitoring should confirm that the CK is trending down. Renal function should be stable/improving. Electrolytes should be normal.
- Patients with mild CK elevation and normal renal function may be discharged after observation phase if CK is trending down.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Follow-up within a few days to recheck CK, electrolytes, and renal function

Patient Monitoring
- Contingent on disease: essential for metabolic myopathies
- Myotoxic drugs should be discontinued/monitored closely.
DIET
- With renal failure, restrict protein intake to lower BUN level.
- Limit potassium intake.
- With anuria, essential to restrict volume intake

PROGNOSIS
Contingent on primary cause of rhabdomyolysis and on recovery from ARF without complications

COMPLICATIONS
- Death, especially from hyperkalemia/renal failure
- With dialysis and supportive care, the prognosis is very good.

CODES
ICD10
- M62.82 Rhabdomyolysis
T79.6XXA Traumatic ischemia of muscle, initial encounter
T79.6XXD Traumatic ischemia of muscle, subsequent encounter

CLINICAL PEARLS

- Elevation of CK is the diagnostic hallmark of rhabdomyolysis.
- The cornerstone of treatment of rhabdomyolysis is aggressive fluid administration.
- Electrolyte abnormalities, acute kidney injury, hepatic injury, compartment syndrome, and (rarely) DIC are the most worrisome complications of rhabdomyolysis.
Rhabdomyosarcoma (RMS) is a malignancy which form part from soft tissue tumors named sarcomas. RMS generates from primitive mesenchymal cells with myogenesis capacity, which matures to striated skeletal muscle tissues. It occurs mainly as primary malignancy but can also be a component of heterogeneous neoplasias, like malignant teratoma.

- Common anatomic sites (1):
  - Head and neck 40% presentation (common in young children, almost always embryonal type)
  - Genitourinary 25% of cases (mostly embryonal type)
  - Musculoskeletal 20% of cases (most common in extremities primary sites in adolescents and adults, alveolar subtype)

- The International Classification of RMS describes four major subtypes:
  - Embryonal RMS (ERMS): represents 60–70% among all RMS. Has early onset and is the most common subtype in children. Commonly presents in the head, neck, and genitourinary areas. ERMS is subdivided into:
    - Classic
    - Botryoid (6% overall embryonal): seen in infants, although can happen <4-year-old patients
    - Spindle cell: 3% of cases and affects young children
  - Alveolar RMS (ARMS): represents 30% of pediatric cases, very aggressive subtype; more common in the trunk, perineum/perianal area, and extremities
  - Anaplastic (children)/pleomorphic (adults) seen in patients aged 30 to 50 years, rarely in children, represents 1% of all RMS, mostly associated with Li-Fraumeni symptoms

Epidemiology

It presents most commonly in children and young adults rather than adult, although when presented in adult ages, is known to be more aggressive and fatal.

Incidence

- 4.5 cases of RMS per 1 million children per year, in children, adolescents, and young adults.
- RMS accounts for 60% of sarcomas in children and adolescents. 50% of pediatric cases occur before the age of 10 years.
- In adults, RMS represents 3% of all soft tissue sarcomas in adults.
- More common in black population than white population

Prevalence

- RMS comprises 3.5% of childhood cancers overall.
- The more frequent in males (male:female ratio, 1:5)
ETIOLOGY AND PATHOPHYSIOLOGY

Genetics
Genetic characteristics vary according to the RMS subtype (2,3):

- **Alveolar:**
  - t(2;13)(q35;q14); causing PAX3-FOXO1 fusion
  - t(1;13)(p36;q14); causing PAX7-FOXO1 fusion
  - t(X;2)(q13;q35); causing PAX3-FOXO4 fusion
  - t(2;2)(q35;p23); causing PAX3-NCOA1 fusion
  - t(2;8)(q35;q13); causing PAX3-NCOA2 fusion
  - t(8;13)(p12;q13); causing FOXO1-FGFR1 fusion

- **Embryonal:**
  - Multiple complex genetic aberrations, including MYOD1 mutations
  - Loss or uniparental disomy of 11p15.5 +2, +8, +11, +12, +13, +20 affecting the genes IGF-2, H19, CDKN1C, and/or HOTS

- **Spindle cell RMS:**
  - 8q13 rearrangements involving SRF-NCOA2 and TEAD1-NCOA2

RISK FACTORS
Although not yet proven, RMS has been associated with high birth weight, large gestational size for age, exposure to recreational drugs and/or radiation while in utero, low socioeconomic status, and the genetic conditions as described below.

COMMONLY ASSOCIATED CONDITIONS
- Beckwith-Wiedemann syndrome (11p15 mutations) presents as fetal overgrowth.
- Costello syndrome (germline HRAS mutations) presents as postnatal growth delay and morphologic abnormalities (including macrocephaly).
- Li-Fraumeni (germline TP53; known as p53 mutations)
- Neurofibromatosis type I (NF1 mutations)
- Noonan syndrome (PTPN11 mutations)
- Pleuropulmonary blastoma (DICER1 mutations)

DIAGNOSIS

HISTORY
- Presents as a progressive nontender palpable mass
- When presents in head/neck, patients report diplopia (due to ophthalmoplegia), recurrent sinusitis, or persistent nasal discharge.
- RMS of genitourinary tissue may present as hematuria, polyuria, vaginal bleeding in females.
- Other symptoms may be noted due to mass effect of the primary or metastatic lesions.
- Personal or family history of genetic syndromes (i.e., NF1, Li-Fraumeni, etc.)

PHYSICAL EXAM
- Painless, enlarging mass
- Polypoid mass protruding from vagina (botryoid)
- Exophthalmos and chemosis (orbital involvement)
- Abdominal pain and compression symptoms (i.e., seizures, visual field defects, nerve palsy,
headaches)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Standard blood test, including complete blood count, serum chemistry, liver function test, and coagulation profile, should be obtained for clinical optimization prior treatment.
- MRI with/without contrast or CT with contrast of the primary tumor (to define anatomy)
- Staging workup:
  - Chest x-ray or CT chest without contrast (preferred). Most common site of metastasis is the lungs. PET/CT scans for lymph node or distant metastases detection that are not readily evident on other imaging. It is also helpful in monitoring the response to treatment for deep, firm lesions >3 cm.
  - Lymph node biopsy

**Diagnostic Procedures/Other**
- For pathology diagnosis:
  - Core needle biopsy, incisional biopsy, or excisional biopsy (based on the size of the mass). The histologic characteristics are similar to others and comprise small, blue, round-cell, which raises the need for advanced immunohistochemical and genetic tests.
  - Histologic classification:
    - Alveolar: rhabdomyoblasts grossly mimicking pulmonary alveoli. The alveolar component must be ≥ 50%; has high levels of myogenin when compared to other subtypes
    - Embryonal:
      - Classic: rhabdomyoblasts configured in sheets, large nest, eosinophilic cytoplasmia; no alveolar pattern, instead poor myofilaments arrangement
      - Botryoid: “grape-like” appearance of rhabdomyoblasts with notable clustering in the subepithelium forming the cambium layer; seen within the vagina and bladder
      - Spindle cell: rhabdomyoblasts with spindle-like appearance
      - Anaplastic (children)/pleomorphic (adults): rhabdomyoblast with large hyperchromatic nuclei and strange mitotic morphologies
  - Immunohistochemical (ICH) markers:
    - Muscle-specific actin, myosin, desmin (in 99% of RMS), myoglobin, Z-band protein, and MyoD1
  - Molecular testing for PAX/FOXO1 fusion, which is tested by PCR and fluorescence in situ hybridization (FISH) with good concordance (94.9%). Although both have similar sensitivity (85.7% vs. 83.3%), PCR seems to have a slightly higher specificity (100% vs. 96%) (4).
  - Although not establish yet, genetic profiling will become the gold standard for diagnosis and prognosis (3).
  - Staging is based on site, size, regional nodal involvement, and distance spread (Table 1).

TREATMENT

Encompasses surgical resection, radiation, chemotherapy. Patients should always be referred to a multidisciplinary team with expertise in oncology for definitive treatment.

SURGERY/OTHER PROCEDURES

- **Surgery:**
  - Local resection of tumor along with metastasis and nodal resection. Lymph node sampling is intended to identify unknown metastasis and guide decision for postop radiation. However, wide resection may not be feasible in cases where grossly impaired functionality results (i.e., head/neck).

- **Radiation therapy (RT):** is widely recommended to enhance local control, except in patients with embryonal type and fusion negative ICH. Emergent RT is only considered in patient with compression symptoms. Proton beam over photon beam due to safety profile. Brachytherapy can be considered in patients with difficult to treat tumor due to location (head/neck and parameningeal).

- **Chemotherapy:**
  - Selected based on prognosis risk stratification assessment (i.e., low, intermediate, high). For nonmetastatic RMS, stratification is made based on the TNM staging as well as the surgical/pathologic clinical grouping system. The latter is determined after the surgical resection based on histopathologic features and extent of residual tumor. In other words, nonmetastatic RMS, risk stratification cannot be fully determined until surgery is performed (3).
    - Gold standard is VAC (vincristine, dactinomycin [also known as actinomycin D], and cyclophosphamide) (5)[A]. Low-risk patients may be prescribed VA instead (5)[A].
    - Most common adverse reactions are:
      - Vincristine: peripheral neuropathy
      - Dactinomycin: myelosuppression and hepatotoxicity
      - Cyclophosphamide: hemorrhagic cystitis (mesna is used for prophylaxis), transitional cell carcinoma, myelosuppression with leukopenia, and infertility
  - In addition, ifosfamide, topotecan, doxorubicin, etoposide, and irinotecan may also be used in alternative regimens.
  - Duration also depends on risk stratification but in general ranges from 12 to 24 months given in separate cycles (usually 14 to 15 cycles) (1).

European Paediatric Soft Tissue Sarcoma Study Group (EPSTSSG) recently demonstrated improve in 3 years survival with maintenance chemotherapy, with vinorelbine and
cyclophosphamide. Although according to COG guidelines, these recommendations cannot be yet establish as standard therapy (6).

- Immune mediated thru natural killer cells are being studied with great potential, although remains in vitro experiment (please refer to Additional Readings).
- Given low frequency of RMS in adults, there are no large trials to set appropriate regimen; therefore, standard VAC is used empirically; although this practice showed low efficacy in some case series, has allow to recommend alternative regimen (doxorubicin, ifosfamide, and vincristine), which demonstrated improvement in short-term (2 years) overall survival and disease-free survival.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

All patients should follow-up with their multidisciplinary team. This allows to monitor treatment response, early detection of locoregional relapse, metastatic disease, or development of secondary malignancies. For this effort, physical exam and imaging surveillance for the first 5 years are paramount (CT/MRI/x-ray). Imaging should be done every 3 months for the 1st year, then every 4 months for the following 2 years, finally every 6 months for next 2 years. After the first 5 years, no more imaging surveillance is recommended as it has not showed further benefits. Other imaging techniques such as bone scan/PET scan should be considered based on clinical decisions, and echocardiograms are recommended if patient received anthracycline therapy (1,7).

PROGNOSIS

- RMS (overall): 70% 5-year survival (1)
- Survival rate has increased from 30% to 51% in adolescents 15 to 19 years old.
- In orbital RMS, survival can be as high as 95%.
- Prognosis as in other tumors depends on size, presence or not of metastasis, and location of the tumor, which help to risk-stratify patients into low, intermediate, and high risk. Favorable sites include orbit/eyelid, head and neck (with no parameningeal involvement), genitourinary (without bladder or prostate involvement), and biliary tract. Unfavorable site: bladder, prostate, extremity, parameningeal, trunk, retroperitoneal, pelvis (1)
- 5-year survival based on PAX/FOXO1 fusion status and risk stratification: low risk + fusion negative 90%; intermediate risk + fusion negative 78%; intermediate risk + fusion positive 56%; high risk + fusion negative 41%; high risk + fusion positive 11% (1)
- In terms of histologic classification, botryoid and spindle cell RMS have favorable prognosis, embryonal subtype has intermediate; sclerosing, spindle cell RMS and alveolar subtype being the poorest, with alveolar RMS being the poorest.
- Adults has worse prognosis when compared to children, not only due to lower rates of treatment adherence and lack of clinical trials identifying best treatment but also due to less favorable location and histopathology and metastasis at time of diagnosis.
- Alveolar subtype has the poorest prognosis; however, any subtype metastatic presentation has bad prognosis (2). Risk factors associated with poorest outcome: metastatic disease at relapse, prior RT treatment, initial tumor size >5 cm, and relapse within 18 months (7)

COMPLICATIONS

- Relapse
Secondary neoplasm
Growth abnormalities
Treatment side effects

REFERENCES

CODES

ICD10
- C49.9 Malignant neoplasm of connective and soft tissue, unsp
- C49.0 Malignant neoplasm of connective and soft tissue of head, face and neck
- C49.5 Malignant neoplasm of connective and soft tissue of pelvis

CLINICAL PEARLS
- RMS are more common in children but can develop in adults, the latest having the highest mortality.
- Genetic disorders and congenital syndromes are associated to a higher risk of developing RMS.
- If localize tumor is identified with concurrent lymph node involvement, implement more aggressive therapy.
- Most common site of metastasis is lung, followed by bone marrow/bone and peritoneum.
- Although improve in survival has not been proven, second look surgery postchemotherapy in patients with documented improved radiology might be beneficial to improve outcome.
- Best timing in RT has not yet been defined.
- For intermediate-risk patient, temsirolimus (mTOR inhibitor) is currently on trial for use.
High-dose chemotherapy followed by autologous stem cell transplant remains a promising therapy to patients who can tolerate side effects and toxicity but still needs further investigation prior to standardization.
RHEUMATIC FEVER
Stuart H. Batten, MD ● Edwin Y. Choi, MD

BASICS

DESCRIPTION
- Acute rheumatic fever (ARF) is an autoimmune, inflammatory response to pharyngeal infection with group A Streptococcus (GAS) that affects multiple organ systems.
- Can lead to rheumatic heart disease (RHD) if not treated in the acute phase
- Largely, a disease of poverty and has disappeared from many affluent parts of the world
- Recurrence in adults and children is common without adequate antibiotic treatment.
- Organ systems affected include cardiovascular, nervous, hematologic, immunologic, lymphatic, skin/exocrine, and musculoskeletal.

Pediatric Considerations
Most cases occur in children ages 5 to 15 years; rare in children <5 years

EPIDEMIOLOGY
- ARF and RHD are largely restricted to low-income countries and marginalized sections of society in wealthy countries.
- Male = female, but females more likely to develop chorea and RHD.
- Endemic regions include South Pacific, indigenous populations of Australia and New Zealand, Africa, Asia.

Incidence
- Worldwide, incidence has been declining for 25 years, attributed to increasing antibiotic use and improved living conditions. The large majority of new cases are in developing countries.
- Mean worldwide incidence ranges from 8 to 51/100,000 school-aged children; 500,000 new cases of ARF occur annually.
- Incidence of ARF in the United States is currently <2/100,000 school-aged children.
- It is estimated that up to 3% episodes of untreated acute GAS pharyngitis go on to develop ARF.

Prevalence
- In developing areas of the world, RHD is estimated to affect >33 million people and is the leading cause of cardiovascular death during the first 5 decades of life.
- Prevalence has been rising due to improved medical care and longer survival (despite decreasing incidence of ARF).

ETIOLOGY AND PATHOPHYSIOLOGY
- ARF is preceded 2 to 3 weeks by GAS (Streptococcus pyogenes) tonsillopharyngitis, a gram-positive bacterial infection.
- Pathogenic mechanism is not completely understood.
- Molecular mimicry plays an important role: The GAS M protein and the carbohydrate antigen (N-acetyl-β-D-glucosamine) share antigenic epitopes with human cardiac tissue and neuronal cells in the basal ganglia. These antigens cross-react with cardiac and vessel endothelial
proteins, leading to an inflammatory cascade.

- Joint involvement is a likely result of immune complex accumulation.

**Genetics**

- Susceptibility is associated with certain genetic polymorphisms of genes involved in the innate and adaptive immune pathways; not fully understood.
- ARF appears to be a heritable and susceptibility is most likely polygenic with variable and incomplete penetrance.
- Increased susceptibility in certain populations, including indigenous Australians, New Zealand Maori, and Pacific Islanders.

**RISK FACTORS**

- Poverty, household crowding, and social disadvantage are the strongest risk factors.
- Genetic susceptibility and ethnic predisposition possibly increase risk.

**GENERAL PREVENTION**

- Primary prevention: Antibiotics are effective at reducing incidence of ARF after known or suspected GAS pharyngitis. Number needed to treat is 100 (3). Appropriate treatment of streptococcal pharyngitis prevents ARF in most cases.
- Secondary prevention: long-term antibiotic prophylaxis (up to 5 to 10 years) to prevent recurrence, which can lead to RHD.

**DIAGNOSIS**

- Mainly a clinical diagnosis
- Laboratory evidence of preceding GAS infection is needed whenever possible (see “Initial Tests (lab, imaging)”)
- Revised 2015 Jones criteria (4)[C]
- Initial ARF: 2 major OR 1 major + 2 minor
- Recurrent ARF: 2 major OR 1 major + 2 minor OR 3 minor

- The revised criteria distinguish between patients with low risk versus moderate to high risk of
having ARF. Patients can be considered low risk if they are from and among a low-incidence group ([C].

**HISTORY**
- ARF typically presents 2 to 3 weeks following GAS tonsillopharyngitis.
- Polyarthritis (35–66%) is often the first symptom, affecting the knees, ankles, elbows, and wrists. Each resolves in days, thus seems to “migrate.” Demonstrates rapid improvement with aspirin or NSAIDs. Usually self-limited <1 month. Moderate- to high-risk patients may only have monoarthritis. Use of NSAID or aspirin may mask the arthritis in initial stages.
- Fever (can be low grade in high-risk populations)
- Erythema marginatum rash (see “Physical Exam”)
- Pancarditis or valvulitis (50–70%) can be subclinical (asymptomatic without auscultatory findings) or clinically apparent (symptomatic or auscultatory findings).
- Sydenham chorea (clinical diagnosis, in 10–30%): neurologic disorder consisting of purposeless, involuntary, nonstereotypical movements
  - 1 to 6 months after infection, lab evidence of preceding infection may be absent.
  - More common in 5 to 15 years old, females
  - Improves or ceases during sleep
  - Can have associated muscular weakness
  - Psychiatric symptoms may have onset prior to chorea, with emotional lability and obsessive-compulsive symptoms.
  - Usually self-resolves over several months and can relapse

**PHYSICAL EXAM**
- Neuro: Sydenham chorea: Involuntary movements may be general or unilateral and may involve the face. “Milkmaid grip” is intermittent hypotonia appreciated on test of grip strength.
- Cardiac: pericardial friction rub, holosystolic murmur of mitral/aortic regurgitation, rarely diastolic; rarely evidence of heart failure
- Skin
  - Subcutaneous nodules (<10%): firm, painless protuberances on extensor surfaces. Usually involves knees, elbow, wrists, occiput, and spinous process of thoracic and lumbar vertebrae; more common in severe ARF, persists up to several weeks
  - Erythema marginatum (5–13%): evanescent, pink rash with pale centers and rounded/serpiginous margins. Blanches with pressure and can be induced with heat. Usually found on trunk and proximal extremities. Rare to be found on face; typically nonpruritic

**DIFFERENTIAL DIAGNOSIS**
- Systemic lupus erythematosus
- Poststreptococcal reactive arthritis
- Juvenile rheumatoid arthritis
- Infectious arthritis
- Myocarditis (viral or idiopathic)
- Innocent cardiac murmur
- Cardiomyopathy
- Tourette syndrome
- Kawasaki syndrome
Pediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS)
Lyme disease
Henoch-Schönlein purpura
Wilson disease
Drug intoxication
Tic disorder
Encephalitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Bacteriologic/serologic evidence of GAS infection is needed whenever possible, and the diagnosis is in doubt when it cannot be obtained (chorea and chronic indolent rheumatic carditis being the exception due to delayed onset).
  - Rapid streptococcal antigen test with high pretest probability
  - Positive GAS throat culture
  - Elevated or rising antistreptococcal antibody titer (ASO or ADB); ASO peaks 3 to 5 weeks postinfection, ADB peaks 6 to 8 weeks. A rise in titer is better than a single titer result.
- ESR and CRP are acute-phase reactants that almost always increase in ARF.
- CBC with differential: leukocytosis, normocytic anemia
- ECG: PR prolongation, AV block, signs of pericarditis
- Joint aspiration and synovial fluid evaluation is indicated if there is significant effusion of one joint or septic arthritis is suspected.
- Echocardiogram: Assesses chamber size and function, pericardial effusion, and valve disease.
- All cases of confirmed OR suspected ARF should have an echocardiogram within 12 weeks (4)[B] due to the 18% prevalence of subclinical carditis.

**Follow-Up Tests & Special Considerations**
- ESR and CRP are useful to monitor the acute disease process. CRP has more utility (ESR remains elevated for months) and can be checked twice weekly initially, followed by every 1 to 2 weeks until normalized.
- Serial echocardiograms can be considered to monitor evolution of carditis, even if not initially present (4)[C].
- All household contacts should be screened with GAS throat cultures. Positive results should be treated with antibiotics, even if asymptomatic.

**Test Interpretation**
Prior treatment with aspirin or steroids may lead to falsely negative lab results.

**TREATMENT**

**GENERAL MEASURES**
- Antibiotic
- Anti-inflammatory agent (aspirin or naproxen)
- Manage other manifestations as needed (e.g., chorea, dysrhythmia, pericarditis, myocarditis, valvular disease, or heart failure).
MEDICATION

First Line
- Eradication: GAS infection treatment should be begun within 9 days of illness to prevent ARF [5][A]. If confirmed diagnosis, begin secondary prophylaxis.
  - If no penicillin allergy
    - Penicillin VK 250 mg PO BID for 10 days, benzathine penicillin G IM for 1 day or amoxicillin 50 mg/kg PO for 10 days (preferred in children) [5][A]
  - If penicillin allergy
    - 1st-generation cephalosporin PO for 10 days, or azithromycin 12 mg/kg PO for 5 days, clindamycin 7 mg/kg/dose PO for 10 days, or clarithromycin 7.5 mg/kg/dose PO for 10 days [5][A]
- Arthritis: Naproxen 10 to 20 mg/kg/day divided BID is now recommended over aspirin [1][B], given superior side-effect profile and less risk of Reye syndrome.
- Carditis: If heart failure, 3rd-degree AV block, or other severe manifestations, appropriate traditional management should be initiated as indicated (diuretics, ACE Inhibitors, vasodilators)
- NSAIDs, glucocorticoids, and IVIG are not recommended for carditis, although glucocorticoids can be considered in severe carditis with acute cardiac failure.
- Chorea: generally self-resolves and does not require treatment, but if symptoms are severe, can use valproic acid or carbamazepine. IVIG and glucocorticoids are restricted to patients who have failed other therapy. Antipsychotics are not routinely used due to extrapyramidal side effects.

Second Line
If penicillin allergy is present, erythromycin is preferred by the New Zealand Guidelines Group but not by the Infectious Diseases Society of America.

ISSUES FOR REFERRAL
- A cardiologist should be involved in management of ARF.
- Pediatric neurologist or movement specialist can help guide therapy with severe chorea.

SURGERY/OTHER PROCEDURES
Valve stenosis is a late sequela that can result from fibrosis and calcification; may require surgical correction (valve repair preferred over replacement) [5]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Initial hospitalization may be helpful for diagnosis and to ensure stability.
- Heart failure requires prompt hospitalization.
- IV fluids
  - Only if signs of dehydration or to augment preload; use caution if heart failure present.
- Nursing
  - Consider bed rest if severe symptoms, with gradual return to ambulation as tolerated.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Secondary prophylaxis: ARF patients should be on a prophylactic antibiotic from time of diagnosis until at least age 21 years, and possibly indefinitely depending on cardiac damage because recurrence can worsen severity of carditis (6)[C].

- First-line prophylaxis is long-acting benzathine penicillin G monthly IM injections (6)[A].
- Penicillin V PO 250 mg BID is an alternative but has risk of nonadherence (6)[B].
- If penicillin allergy, treat with sulfadiazine 0.5 to 1.0 g daily (6)[B].
- If penicillin and sulfad drug allergy, treat with azithromycin (6)[C].
- Patients on penicillin prophylaxis who develop GAS pharyngitis while on penicillin should be treated with an alternative agent such as clindamycin.

If diagnostic uncertainty exists, consider 1 year of secondary antibiotic prophylaxis followed by reassessment and echocardiogram (4)[C].

Routine antibiotic prophylaxis for dental procedures is no longer recommended by the American Heart Association for patients with RHD (6).

Have low threshold to test and treat episodes of acute tonsillopharyngitis in children.

**Patient Monitoring**
Initially weekly and then every 6 months

**Pediatric Considerations**
- Use aspirin with caution in children given the risk of Reye syndrome.
- Naproxen has been found equivalent to aspirin with fewer risks in ARF, in a randomized, placebo-controlled study (1)[B].

**Pregnancy Considerations**
May exacerbate valve disease, particularly mitral stenosis in RHD. Refer pregnant patients to a cardiologist.

**DIET**
No dietary restrictions; low-sodium if heart failure present

**PATIENT EDUCATION**
American Heart Association: [http://www.heart.org](http://www.heart.org)

**PROGNOSIS**
Long-term sequelae are generally limited to the heart and depend on the severity of carditis during an acute attack.

**COMPLICATIONS**
- Recurrence of ARF due to GAS reinfection
- RHD can occur 10 to 20 years after ARF, with mitral more common than aortic regurgitation, can lead to mitral stenosis. Heart failure is the worst complication.
- Jaccoud arthropathy is chronic and involves painless deformities of hands/feet.

**REFERENCES**

CODES

ICD10
- I00 Rheumatic fever without heart involvement
- I01.9 Acute rheumatic heart disease, unspecified
- I01.0 Acute rheumatic pericarditis

CLINICAL PEARLS

- ARF is an autoimmune, inflammatory disease that follows a GAS pharyngeal infection and affects multiple organ systems, most notably, the heart.
- Modified Jones criteria now delineate between low risk and moderate/high risk patients. Initial diagnosis requires two major or one major plus two minor manifestations in the context of a preceding documented GAS infection.
- Treatment involves antibiotic eradication followed immediately by long-term antibiotic prophylaxis. Supportive care includes NSAIDs such as naproxen or aspirin.
RHINITIS, ALLERGIC
Parth Sharad Rajyaguru, MD, MPH

BASICS
Allergic rhinitis is the collection of symptoms involving mucous membranes of nose, eyes, ears, and throat after an exposure to allergens such as pollen, dust, or dander.

DESCRIPTION
- Immunoglobulin E (IgE)-mediated inflammation of the nasal mucosa following exposure to an extrinsic protein; an immediate symptomatic response is characterized by sneezing, congestion, and rhinorrhea followed by a persistent late phase dominated by congestion and mucosal hyperreactivity.
- Allergic rhinitis can be classified into seasonal or perennial and can be intermittent or persistent.
- Seasonal responses are usually due to outdoor allergens such as tree pollen, flowering shrubs in spring, grasses and flowering plants in summer, and ragweed and mold in fall.
- Perennial responses, or year-round symptoms, are usually associated with indoor allergens like dust mites, mold, and animal dander.
- Occupational allergic rhinitis is caused by allergens at the workplace and can be sporadic or year-round.
- Nonallergic rhinitis (e.g., vasomotor, rhinitis of pregnancy, and rhinitis medicamentosa) can occur.

Pediatric Considerations
Chronic nasal obstruction can result in facial deformities, dental malocclusions, and sleep disorders.

Pregnancy Considerations
Physiologic changes during pregnancy may aggravate all types of rhinitis, frequently in the 2nd trimester.

EPIDEMIOLOGY
- Onset usually in first 2 decades, rarely before 6 months of age, with tendency declining with advancing age
- The mean age of onset is 8 to 11 years, and about 80% of cases have established allergic rhinitis by age 20 years.

Prevalence
- ~10–25% of the U.S. adult population and 9–42% of the U.S. pediatric population are affected.
- 44–87% of patients with allergic rhinitis have mixed allergic and nonallergic rhinitis, which is more common than either pure form (1).
- Scandinavian studies have demonstrated cumulative prevalence rate of 14% in men and 15% in women.

ETIOLOGY AND PATHOPHYSIOLOGY
- Aeroallergen-driven mucosal inflammation due to resident and infiltrating inflammatory cells
as well as vasoactive and proinflammatory mediators (e.g., cytokines)

- **Inhalant allergens:**
  - Perennial: house dust mites, indoor molds, animal dander, cockroach/insect detritus
  - Seasonal: tree, grass, and weed pollens; outdoor molds
  - Occupational: latex, plant products (e.g., baking flour), sensitizing chemicals, and certain animals for people working in farms and vet clinics

**Genetics**
Complex but strong genetic predilection present (80% have family history of allergic disorders)

**RISK FACTORS**
- Family history of atopy, with a greater risk if both parents have atopy
- Higher socioeconomic status
- Tobacco smoke can exacerbate symptoms and increase risk of developing asthma in patients with allergic rhinitis.
- Having other allergies such as asthma
- Unclear evidence regarding risk due to early, repeated exposure to offending allergen and early introduction of solid food
- Pets in house and houses infested with cockroaches can cause perennial allergic rhinitis.

**GENERAL PREVENTION**
- Primary prevention of atopic disease has not been proven effective by maternal diet or maternal allergen avoidance (2).
- Exclusive breastfeeding to 6 months of age lowers risk of some atopic disorders.
- Symptomatic control by environmental avoidance is the “first-line treatment.”
- No evidence to support use of acaricides with mite-proof mattress and pillow covers, carpet and drape removal, removal of plants in the home, and pet control (2),(3)[B]
- Air conditioning and limited outside exposure during allergy season (1)[B]
- HEPA air cleaners and vacuum bags of unclear efficacy
- Close doors and windows during allergy season.
- Use a dehumidifier to reduce indoor humidity.

**COMMONLY ASSOCIATED CONDITIONS**
Other IgE-mediated conditions: asthma, atopic dermatitis, allergic conjunctivitis, food allergy

**DIAGNOSIS**
Diagnosis is made primarily by history and physical exam.

**HISTORY**
- Evaluation of nature, duration, and time course of symptoms
- History of atopic dermatitis and/or food allergies
- History of nasal congestion; rhinorrhea; pruritus of nose, eyes, ears, and/or palate; sneezing; itching; and watering eyes
- Family history of allergic diseases
- History of environmental and occupational exposure and various nasal stimuli can help differentiate between allergic and vasomotor rhinitis.
PHYSICAL EXAM
Many findings are suggestive of but not specific for allergic rhinitis:
- Dark circles under eyes, “allergic shiners” (infraorbital venous congestion)
- Transverse nasal crease from rubbing nose upward; typically seen in children
- Rhinorrhea, usually with clear discharge
- Pale, boggy, blue-gray nasal mucosa
- Postnasal mucus discharge
- Oropharyngeal lymphoid tissue hypertrophy

DIFFERENTIAL DIAGNOSIS
- Infectious rhinitis: usually viral, commonly with secondary bacterial infection
  - Usually associated with sinusitis and is known as rhinosinusitis
  - Viral rhinitis averages six episodes per year from ages 2 to 6 years.
  - IgA deficiency with recurrent sinusitis
- Rhinitis medicamentosa (RM):
  - Rebound effect associated with continued use of certain medications; topical decongestant drops and sprays are most common
  - Other medications that may induce RM include: angiotensin-converting enzyme inhibitors, reserpine, β-blockers, oral contraceptive pills (OCPs), guanethidine, methyldopa, aspirin, nonsteroidal anti-inflammatory drugs
- Vasomotor (idiopathic) rhinitis caused by numerous nasal stimuli such as warm or cold air, scents and odors, light or particulate matter
- Hormonal: pregnancy, thyroid, OCPs
- Nonallergic rhinitis with eosinophilia syndrome (NARES)
- Gustatory: watery rhinorrhea in response to alcohol or food
- “Skier’s nose”: watery rhinorrhea in response to cold air
- Conditions associated with rhinitis:
  - Nasal polyps, tumor
  - Septal/anatomic obstruction
    - Adenoidal hypertrophy, particularly in children
    - Septal abnormality or deflected nasal septum (DNS) in adults

DIAGNOSTIC TESTS & INTERPRETATION
- Lab tests rarely needed
- Skin testing is done to identify the allergen for immunotherapy.

Initial Tests (lab, imaging)
- Testing is rarely indicated.
- If diagnosis implies other causes, consider the following:
  - Complete blood count with differential may show elevated eosinophils.
  - Increased total serum IgE level
  - Nasal probe smear may show elevated eosinophils.
- Medications that may alter lab results
  - Corticosteroids may decrease eosinophilia.
  - Antihistamines suppress reactivity to skin tests; stop antihistamines 7 days before testing.
- CT scan of sinuses is not routinely done but can be used to check for complete opacity, fluid level, and mucosal thickening.
Diagnostic Procedures/Other
- Consider testing in only those cases where allergic symptoms do not respond to treatment and/or considering immunotherapy.
- Specific allergen sensitivity with allergen skin testing or radioallergosorbent test (RAST); clinical correlation based on history is essential in interpreting results.
- Diagnostic allergen prick tests are used to select agent to determine appropriate environmental control measures as well as to direct immunotherapy:
  - Prick or puncture: superficial injury to epidermis with application of test antigen
  - Intradermal
- RAST: more expensive and less sensitive than skin testing; typically used in patients in whom skin testing is not practical or a severe reaction is possible
- Rhinoscopy: useful to visualize intranasal anatomy and posterior pharyngeal structures, including adenoids, polyps, and larynx

Test Interpretation
- Nasal washing/scraping: Eosinophils predominate but may see basophils, mast cells.
- Nasal mucosa: submucosal edema but without destruction; eosinophilic infiltration; congested mucous glands and goblet cells

TREATMENT
There are three mainstays of treatment of allergic rhinitis:
- Allergen avoidance
- Medication
- Allergy immunotherapy

GENERAL MEASURES
- Establish specific cause(s) by history and appropriate testing.
- Limit exposure to offending allergen.
- Allergen immunotherapy (desensitization)
  - Reserved when symptoms are uncontrollable with medical therapy or have a comorbidity (e.g., asthma)
  - Specific allergen extract is injected SC in increasing doses to induce patient tolerance.

MEDICATION
Oral medication and intranasal sprays are commonly used.

First Line
- Mild symptoms: 2nd-generation nonsedating antihistamines are the first-line therapy for mild to moderate allergic rhinitis (1,4).
- Adverse effects: mild sedation, mild anticholinergic effects
- Generic (cetirizine, fexofenadine, loratadine; most to least effective)
  - Levocetirizine is a 2nd-generation nonsedating antihistamine that is effective but costly.
- Intranasal corticosteroids are first-line therapy for moderate to severe allergic rhinitis (1,4)[A]:
  - Most effective drug class for symptoms of allergic rhinitis
  - Use nasal sprays after showering and direct spray away from septum to improve deposition on mucosal surface.
- May be used as needed; however, more effective with daily use (1)
- Adverse effects: nosebleed, nasal septal perforation, and systemic corticosteroid effects
- Ciclesonide is a new-generation corticosteroid with previously demonstrated efficacy in the treatment of asthma when delivered through a metered-dose inhaler. Ciclesonide is also currently in clinical development as an intranasal formulation for use in the treatment of AR.
- Systemic steroids should be considered only in urgent cases and only for short-term use.

**Second Line**
- Nasal antihistamines effective but may be systemically absorbed and may cause sedation: azelastine, olopatadine
- 1st-generation antihistamines, such as the following:
  - Brompheniramine: 12 to 24 mg PO BID
  - Chlorpheniramine: 4 mg PO q4–6h PRN
  - Clemastine: 1 to 2 mg PO BID PRN
  - Diphenhydramine: 25 to 50 mg PO q4–6h PRN:
    - May precipitate urinary retention in men with prostatism and/or hypertrophy
    - Adverse effects: sedation, prolonged QT interval, performance impairment, and anticholinergic effect
- Decongestants
  - Phenylephrine: 10 mg PO q4h PRN
  - Pseudoephedrine: 60 mg PO q4–6h PRN
  - Oxymetazoline nasal spray (Afrin): 2 to 3 sprays per nostril q10–12h PRN (max 3 days).
    - Intranasal agents should not be used for >3 days due to rebound rhinitis. Discourage use in patients with hypertension (HTN) or cardiac arrhythmia.
- Intranasal anticholinergics such as ipratropium nasal spray 2 sprays per nostril BID–TID
  - Intranasal anticholinergics can increase efficacy in combination with steroid use.
- Leukotriene antagonists such as montelukast 10 mg/day PO
  - Should generally be used as an adjunct, not monotherapy
  - May be first line in those with concomitant asthma
- Mast cell stabilizers such as cromolyn nasal spray 1 spray per nostril TID–QID
  - May take 2 to 4 weeks of therapy for optimal efficacy
  - May be ineffective in patients with nonallergic rhinitis and nasal polyps

**ISSUES FOR REFERRAL**
Refer to allergist for consideration of immunotherapy.

**ADDITIONAL THERAPIES**
- Nasal saline use has evidence of efficacy as sole agent or as adjunctive treatment (1,5)[A].
- Other treatment strategies
  - When initiating intranasal steroids, consider starting with a “burst,” using 2 sprays in each nostril daily for 2 weeks and then decreasing to 1 spray in each nostril daily thereafter (6).
  - To mitigate long-term side effects of intranasal steroids, consider a “5 days on, 2 days off” strategy, with the days off being the days of lowest exposure to allergens (6).

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS
No specific restrictions on activity; emphasize avoiding activity where exposure to the allergen is likely.

Patient Monitoring
Initiation of patient education is critical.

DIET
- No special diet unless concomitant food reactions are suspected and evaluated
- Some patients with severe sensitivity to seasonal pollens may have oral allergy syndrome, which is associated with itching in the mouth with the ingestion of fresh fruits that may cross-react with the allergens.

PATIENT EDUCATION
- Asthma and Allergy Foundation of America, 1717 Massachusetts Ave., Suite 305, Washington, DC 20036; (800) 7-ASTHMA: http://www.aafa.org/

PROGNOSIS
- Acceptable control of symptoms is the goal.
- Treatment is helpful to reduce the risk of comorbidities, such as sinusitis and asthma.

COMPLICATIONS
- Secondary infection such as otitis media or sinusitis
- Epistaxis
- Nasopharyngeal lymphoid hyperplasia
- Airway hyperreactivity with allergen exposure
- Asthma
- Facial changes, especially in children who are mouth breathers
- Sleep disturbance

CODES

ICD10
- J30.9 Allergic rhinitis, unspecified
- J30.1 Allergic rhinitis due to pollen
- J30.2 Other seasonal allergic rhinitis

CLINICAL PEARLS
- Nasal saline irrigation (flushing 6 to 8 oz) may be very helpful in clearing upper airway of secretions and may precede the use of nasal corticosteroids.
- 2nd-generation antihistamines and intranasal corticosteroids are first-line therapies for allergic rhinitis.
Rocky Mountain spotted fever (RMSF) is one of the spotted fever rickettsioses (SFR) and is the most common of the rickettsial infections in North America. It is associated with the highest rates of severe and fatal outcomes of all reportable rickettsial diseases in the United States (1)(A),(2)(C).

**DESCRIPTION**
- RMSF is a potentially fatal tick-borne systemic small and medium vessel vasculitis caused by the bacterium *Rickettsia rickettsii* (2)(C).
- Symptoms include fever, headache, and myalgia followed by a macular rash; begins at wrists and ankles, spreading toward palms, soles, and the trunk
- System(s) affected: cardiovascular, musculoskeletal, skin, central nervous system (CNS), renal, hepatic, and pulmonary
- SFR are difficult to diagnose because early signs and symptoms are nonspecific and acute-phase diagnostic tests are not widely available; however, early intervention and treatment are key (3)(C).

**EPIDEMIOLOGY**
In the United States, ticks are both vectors and main reservoirs. They become infected either transovarially or by feeding on an infected animal (deer, dog, livestock). Important species in the U.S. include the American dog tick, *Dermacentor variabilis* in the eastern two-thirds of the U.S.; the Rocky Mountain wood tick, *Dermacentor andersoni* in the western U.S.; and the Brown dog tick, *Rhipicephalus sanguineus* is distributed throughout all states (1)(A),(3)(C).

**Incidence**
- In the United States, the annual incidence of SFR increased from 1.7 cases per million persons in 2000 to 13.2 in 2016. Cases have been reported in all states except Hawaii and Alaska. RMSF also seen in Canada, Mexico, and throughout Central and South America (4)(B).
- North Carolina, Arkansas, Missouri, Oklahoma, and Tennessee account for over 60% of cases (1)[A]
- Cases occur year round. Most are reported during April to September during the peak of outdoor activity (1)[A].
- All ages are susceptible; highest incidence occurs in age 60 to 69 years. Highest case-fatality rate is in children <10 years (1)[A].

**Prevalence**
In the United States, 4,470 cases were reported in 2012. <0.1% of ticks carry virulent rickettsial species.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- An adult tick releases *R. rickettsii*, an obligate intracellular gram-negative coccobacilli, from
Pathogens infect vascular endothelial cells, causing small and medium vessel injury throughout the body leading to disseminated inflammation. This leads to microhemorrhages and increased vascular permeability causing pulmonary and cerebral edema. Local consumption of platelets results in the characteristic petechial rash.

Subsequent end-organ injury may also result in meningoencephalitis, ARF, acute respiratory distress syndrome, shock, arrhythmia, and seizure (1).

Symptoms appear 3 to 12 days after bite or between 4 to 8 days after discovery of an attached tick. Incubation period is typically 5 days or less.

It is unknown whether R. rickettsii crosses the placenta and causes in utero infection.

R. rickettsii has one of the smallest bacterial genomes (1.1 to 1.6 Mb), making the organism highly adapted to the intracellular environment.

**RISK FACTORS**
- Known tick bite, engorged tick, or presence of tick for >20 hours. The likelihood of infection increases with the duration of tick attachment.
- Tick crushed during removal
- Accumulated outdoor exposure or residence in wooded areas
- Contact with outdoor pets or wild animals

**GENERAL PREVENTION**
- Limit tick exposure when possible in endemic areas, highest tick exposure with time spent in tall grasses, open areas of low bushy vegetation, or wooded areas.
- Wear light-colored clothing, long sleeves, pants, socks, and closed-toed shoes.
- Use DEET-containing insect repellents.
- Permethrin spray on clothing
- Regular tick checks
- Prompt and proper tick removal
- Wash hands and site of bite with soap and water after tick removal to avoid potential mucosal inoculation.
- Nail polish, petrolatum jelly, and heat do not aid in tick removal. Do not use bare hands to remove ticks.
- Protect pets through ectoparasite control (1)[A].
- Prophylactic antibiotic treatment is not recommended.

**DIAGNOSIS**
- It is important to have high incidence of suspicion for rickettsial infections when patients present with “influenzalike” symptoms during summer months regardless of a known history of tick exposure (2)[C].
- Delay of empirical therapy increases risk of long-term sequelae and mortality.

**HISTORY**
Consider RMSF in acute febrile illness and rash, particularly with a history of potential tick exposure within previous 14 days; outdoor activities or travels to an endemic area, during late spring or summer months. The tick bite goes unnoticed 30–50% of the time.

- Typically presents like a viral illness in the first 1–4 days with sudden onset of fever, severe frontal headache, malaise, myalgia, anorexia, nausea, vomiting, and photophobia (1).
- RMSF is easily mistaken for gastroenteritis, pharyngitis, or mononucleosis.
- Rash typically appears 2 to 4 days after onset of fever; starts as a small blanching, pink macules on wrist and ankles before spreading to the trunk where rash may become maculopapular in appearance.
- Involvement of palms and soles usually present by 5th to 6th day, along with generalized petechial rash; a sign of advanced disease
- Although children <15 years more frequently (>90%) have a rash, the classic triad of fever, rash, and tick bite occurs in <60% of children with RMSF. 10% of patients never develop a rash and decision to treat should not be based on presence of rash (1)[A].
- Other symptoms include conjunctival injection, mental status impairments, restlessness, arthralgia, peripheral or periorbital edema, calf pain, and hearing loss (1)[A].

PHYSICAL EXAM

- Fever is typically >102°F with relative bradycardia
- The rash typically starts as an erythematous, macular, or maculopapular exanthema (1 to 5 mm in diameter); 50% become petechial or purpuric; blanchable and generally spares the face
- Rash can be difficult to visualize on dark skin.
- 20% never develop the “classic” rash. Do not rely solely on the presence or absence of the typical rash for diagnosis.
- In severe cases, the rash can involve the entire body (including mucous membranes) and may progress to necrotic or gangrenous lesions.
- The rash is not associated with pruritus or urticaria; if present, this makes RMSF less likely.
- AMS, lymphadenopathy, diffuse right upper quadrant pain, hepatosplenomegaly, and edema of dorsum of hands or feet

DIFFERENTIAL DIAGNOSIS

- Viral exanthema (e.g., hand-foot-mouth disease, measles, rubella, roseola)
- Viral gastroenteritis, mononucleosis
- Upper respiratory infection, urinary tract infection, TTP/ITP, idiopathic vasculitides, toxic shock syndrome
- Meningoencephalitis, meningococcemia
- Other tick-borne infections: typhus, ehrlichiosis, Lyme disease
- Leptospirosis
- Drug reaction or serum sickness
- Kawasaki disease
- Infective endocarditis

DIAGNOSTIC TESTS & INTERPRETATION

Currently, most cases of RMSF are diagnosed based on IgM and IgG serologic response to R. rickettsiae, in conjunction with a high degree of clinical suspicion. Do not delay therapy awaiting results (2)[C].

Initial Tests (lab, imaging)
Specific laboratory diagnosis

- Indirect fluorescent antibody (IFA) testing is gold-standard for serology.
- Sensitivity of IFA 2 weeks after onset of illness is 94–100%, but cannot distinguish between R. rickettsii and other spotted fever-group rickettsiae (3)[C].
- Due to seroprevalence it is impossible to differentiate a single elevated IgG titer associated with acute illness from previous infections (4)[B].
- Testing two sequential serum or plasma samples allows demonstrating rising IgG or IgM antibody levels, which is essential to confirm acute infection. Paired serum specimens taken early (i.e., acute) and later (i.e., convalescent) in the disease course represent the preferred specimens for evaluation (4)[B].
- Typically, these specimens should be taken at least 2–3 weeks apart to examine for a 4-fold or greater increase in antibody titer to confirm diagnosis (3)[C].
- Detectable antibody response develops 7 to 10 days after exposure; optimal time for testing is 14 to 21 days after symptom onset.

Nonspecific laboratory tests

- White blood cell count: variable, frequently normal and will not help rule out rickettsial infection
- Platelet: thrombocytopenia (<150,000 cells/µL) in 60% of kids
- Hyponatremia <135 mEq/dL, and elevated hepatic transaminases in 50% of patients
- Anemia, increase in blood urea nitrogen/creatinine, PT/PTT, hyperbilirubinemia, and hypoalbuminemia may also be present.
- Cerebrospinal fluid may have mononuclear pleocytosis and elevated protein, and normal glucose (1)[A],(3)[C].

Other than occasional nonspecific pneumonic infiltrates on chest radiograph, imaging procedures are rarely helpful.

Diagnostic Procedures/Other

- Skin biopsy can also offer definitive diagnosis; a 3-mm punch biopsy to perform a rapid direct fluorescent antibody (DFA) test (sensitivity 70%, specificity 100%)
- Rickettsial DNA detection using PCR of skin biopsy samples is a new approach to diagnosis of up to 60–70% of suspected rickettsial infections during the acute-phase of illness (5)[A]
- Qualitative enzyme-linked immunosorbent assay

Test Interpretation

- Test acute and convalescent phase sera in tandem.
- Early treatment may limit antibody formation.
- Seropositivity increases with age in endemic states. Positive spotted fever group Rickettsia antibody does not necessarily signify an acute infection.
- Petechiae due to the vasculitis may be seen on organ surfaces (e.g., liver, brain, or epicardium).

TREATMENT

MEDICATION

First Line
Doxycycline is the treatment of choice in both adults and children (1)[A],(2)[C],(3)[C].
- Untreated rickettsial infections have a high rate of morbidity and mortality (20–30% without
prompt antibiotic treatment. Other antibiotics are considerably less effective (2)[C].

- **Adults:** Doxycycline 100 mg PO or IV q12h until three days after the fever subsides (1)[A],(3)[C]
- **Children <18:** Doxycycline 100 mg PO or IV q12h until 3 days after fever subsides (3)[C]
- **Pregnancy:** Doxycycline 100 mg PO or IV q12h until 3 days after fever subsides is first-line therapy and chloramphenicol 50–75 mg/kg IV divided into 4 doses daily for 7 days is second-line therapy (3)[C]
- Fever typically subsides within 24 to 48 hours with early treatment; longer if patient is severely ill. If promptly treated, and patient lacks response to doxycycline in 48 hours, consider an alternate diagnosis.
- RMSF resistance to doxycycline has not been documented.
- Adverse effects may include
  - Dyspepsia. Take medication with food and water. Avoid dairy, iron, or antacids, as they may inhibit drug absorption.
  - Photosensitivity may occur. Minimize sun exposure and use sunscreen.
  - No risk of dental staining in children <8 years old (1)[A],(2)[C]
- Severe allergy is a contraindication to doxycycline; rapid desensitization may be considered for life-threatening disease in severe illness.

**Second Line**

- Chloramphenicol is the alternative to treat RMSF; associated with adverse hematologic effects (e.g., aplastic anemia) and increased case mortality (1)[A]
- Fluoroquinolones have in vitro activity against rickettsiae but no human efficacy data. They are not currently recommended for treatment (1)[A].
- Sulfamethoxazole-trimethoprim is compatible with breastfeeding (1)[A].

**Pregnancy Considerations**

- Doxycycline is appropriate for this life-threatening infection in pregnancy if suspicion is high, despite the potential risk to fetal bones/teeth along with maternal hepatotoxicity and pancreatitis (1)[A],(3)[C]
- Current evidence, while limited, suggests no increased risk of teratogenicity. Studies have found an association between tetracyclines and hepatotoxicity in pregnant females, but the doses exceeded those used to treat RMSF (3)[C].
- Short-term doxycycline is compatible with breastfeeding (1)[A].
- Chloramphenicol may be considered but should be avoided in the 3rd trimester due to risk for gray baby syndrome.

**ISSUES FOR REFERRAL**

- Consider infectious disease consult along with immunology/allergist if patient is severely allergic to doxycycline.
- Report cases of RMSF to public health authorities.

**ADDITIONAL THERAPIES**

Patients with neurologic injury may require prolonged physical and cognitive therapy.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admission criteria/initial stabilization
  - CNS dysfunction
– Nausea/vomiting preventing oral antibiotic therapy
– Immunocompromised patients
– Specific acute organ failure
– Failure of oral pain management
– ICU for patients with shock

● Discharge criteria
  – Resolution of fever
  – Ability to take oral therapy and nutrition

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

● Patients with mild disease may be treated as outpatients if close follow-up is available.
● Hospitalize patients with moderate to severe disease.
● Infection does not confer lifelong immunity.

Patient Monitoring

● Follow patients treated as outpatients every 2 to 3 days until symptoms resolve.
● Follow up CBC, electrolytes, liver function tests if clinically indicated.

DIET

Consider nutritional supplementation if intake is poor.

PATIENT EDUCATION

General prevention and caution regarding tick avoidance during outside activities in endemic areas

PROGNOSIS

● Prognosis is closely related to timely administration of appropriate antibiotics.
● Delay in treatment may increase mortality by 3-fold if delayed to 5th day of illness (1)[A].
● When treated promptly, prognosis is excellent with resolution of symptoms and no sequelae.
● Children aged <10 years and elderly >70 years are at higher risk of morbidity and/or mortality.
● Patients with G6PD deficiency are at highest risk for fulminant RMSF, in which death can occur ≤5 days.

COMPLICATIONS

● Encephalopathy, most commonly transient impaired level of consciousness or meningismus
● Seizures, focal neurologic deficit
● Renal injury leading to acute renal failure
● Hepatitis, congestive heart failure (CHF), respiratory failure
● Proximal muscle weakness, changes in personality, paresthesias, deafness, secondary thromboses, and tissue necrosis may also be seen.

CODES
ICD10
A77.0 Spotted fever due to Rickettsia rickettsii

CLINICAL PEARLS

- Diagnosis of RMSF requires a high index of clinical suspicion.
- Tick bites are often unnoticed, and some patients may never develop a rash.
- Begin treatment immediately in suspected cases. Doxycycline is drug of choice for RMSF in both adults and children. The only absolute contraindication is severe allergy to the drug.
- Do not wait for confirmatory laboratory testing prior to beginning treatment of suspected cases.
- There is no evidence to support prophylaxis against RMSF in patients with known tick bite (2) [C].
- RMSF is not transmissible from person to person (2)[C].
- There is no available RMSF vaccine (2)[C].
ROSEOLA
Jeffrey D. Quinlan, MD, FAAFP

BASICS
Omnipresent infection occurring in infancy and childhood. Majority of cases are caused by human herpesvirus 6 (HHV-6); may be associated with other diseases including encephalitis

DESCRIPTION
- Acute infection of infants or very young children (1)
- Causes a high fever followed by a skin eruption as the fever resolves (1)
- Transmission via contact with salivary secretions or respiratory droplet (1)
- Incubation period of 9 to 10 days (1)
- System(s) affected: skin/exocrine, metabolic, gastrointestinal, respiratory, neurologic
- Synonym(s): roseola infantum, exanthem subitum; pseudorubella; sixth disease; 3-day fever (1)

Pediatric Considerations
A disease of infants and very young children (2)

EPIDEMIOLOGY
- Predominant age
  - HHV-6
    - Infants and very young children (<2 years old) (3)
    - Peak age infection 6 to 9 months, rarely congenital or perinatal infection (1)
    - 95% of children have been infected with HHV-6 by 2 years of life.
  - HHV-7
    - Later childhood
    - Mean age of infection 26 months
    - >90% population with HHV-7 by 10 years (1)
- Predominant sex: male = female (1)
- No seasonal variance

Incidence
Common—accounts for 20% ED visits for febrile illness among children 6 to 8 months (4)

Prevalence
- Peak prevalence is between 9 and 21 months (3).
- Nearly 100% population carrying HHV-6 by 3 years (1)
- Approximately 20% patients with primary HHV-6 have roseola (4).

ETIOLOGY AND PATHOPHYSIOLOGY
- HHV-6 and HHV-7 (2)
- Majority of cases (60–74%) due to HHV-6
  - HHV-6B > HHV-6A (2)
  - HHV-6A seen in children in Africa
  - HHV-6 binds to CD46 receptors on all nucleated cells (2).
Primary infection typically through respiratory droplets or saliva
- Congenital infection/vertical transmission occurs in 1% of cases (1).
  - Transplacental transmission
  - Chromosomal integration (clinical significance unknown)
- Lifelong latent or persistent asymptomatic infection occurs after primary infection (1).
  - 80–90% of population intermittently sheds HHV-6/HHV-7 in saliva (2).
  - Patients are viremic from 2 days prior to fever until defervescence and onset of rash.
  - HHV-6 latency is also implicated in CSF (4).

Genetics
HHV-6 is integrated into the chromosomes of 0.2–3.0% of the population. This leads to vertical transmission of the virus. Clinical significance of this is unknown (1).

RISK FACTORS
- Female gender (3)
- Having older siblings (3)
- At-risk adults: immunocompromised (5)
  - Renal, liver, other solid organ, and bone marrow transplant (BMT) (3)
  - HHV-6 reactivation can occur in 1st week posttransplant (5). HHV-6 viremia occurs in 30–45% of BMT within the first several weeks after transplantation (4).
    - Usually asymptomatic (4)
    - Up to 82% of HHV-6 reactivation/reinfection in solid organ transplant (5)
- Nonrisk factors (3)
  - Child care attendance
  - Method of delivery
  - Breastfeeding (HHV does not appear to pass through breast milk.)
  - Maternal age
  - Season

DIAGNOSIS

HISTORY
- 3 to 5 days abrupt fever 102.2–104.0°F (39–40°C) not associated with a rash (1)
- The child may be fussy during this prodrome (1,6).
- Sudden drop of fever associated with appearance of rash (1)
  - Rash on trunk then spreads centrifugally mainly to neck, possibly also to peripheral extremities, and face
- Diarrhea (3)
- Mild upper respiratory symptoms (3)
- Rhinorrhea (3)
- Febrile seizure occurs in 13% of cases (1).

PHYSICAL EXAM
- Rash (exanthem subitum) (1)
  - Rose-pink macules and/or papules that blanch
  - First appears on the trunk then peripherally
  - May occur up to 3 days after fever resolves (1)
– Fades within 2 days
– Occurs in approximately 20% of patients in the United States (1)

- Mild inflammation of tympanic membrane, pharynx, and/or conjunctiva (1,6)
- Ulcers on soft palate and uvula (Nagayama spots) (1)
- Cervical lymphadenopathy (1)
- Periorbital edema (2)

**DIFFERENTIAL DIAGNOSIS**
- Enterovirus infection
- Adenovirus infection (1)
- Epstein-Barr virus
- Fifth disease—parvovirus B19
- Rubella (1)
- Scarlet fever (1)
- Drug eruption (1)
- Measles (1)

**DIAGNOSTIC TESTS & INTERPRETATION**
- Primarily a clinical diagnosis not requiring laboratory or radiologic testing (1)[C]
- Tests often cannot differentiate latent or active disease (1)[C].
- Specific diagnosis only necessary in severe cases, unclear diagnosis where more serious disease needs to be ruled out, or if considering antiviral therapy (1)[C]

**Initial Tests (lab, imaging)**
- HHV-6 and HHV-7 by PCR (1,5)[C]
  – Serum, whole blood, CSF, or saliva
  – Becoming more widely available
  – Not required in non-immunocompromised individuals
- HHV-6 IgM immunofluorescence (1)
  – Diagnostic for acute infection
  – Spike seen in 1st week of illness
- HHV-6 IgG immunofluorescence (1)
  – Check at diagnosis and then 2 weeks later.
  – Use with IgM to show primary infection.
  – Negative initial test and rise on follow-up suggest primary infection.
- Viral culture (5)
  – Rarely done
  – No clinical use (very time-consuming)
- Other laboratory findings (1)
  – Decreased total leukocytes, lymphocytes, and neutrophils
  – Elevated transaminases
  – Thrombocytopenia

**Diagnostic Procedures/Other**
- Urine culture: to rule out UTI as source of fever (2)
- Chest x-ray (CXR): if a child has respiratory symptoms
TREATMENT

No treatment necessary, resolves without sequelae (1)[C]

GENERAL MEASURES

- Symptomatic relief including antipyretics (1)[C]
- Hydration (1)[C]

MEDICATION

First Line

- No specific first-line treatment in immunocompetent hosts beyond supportive measures (2)[C]
  - Antivirals are not recommended in immunocompetent.
- No approved antiviral treatment in immunocompromised (2)[C]
- Second-line IV ganciclovir, cidofovir, foscarnet tested in vitro studies in stem cell transplant patients
  - HHV-6B susceptible: ganciclovir and foscarnet (5)[C]
  - HHV-6A and HHV-7 are more resistant to ganciclovir (5).
- Antivirals suggested in individual cases of encephalitis (associated with reactivation of HHV-6) (5)
  - In bone marrow and stem cell transplant recipients receiving immunosuppression, ganciclovir prophylaxis is effective in preventing reactivation of HHV-6 (6)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- During febrile prodrome, monitor for dehydration.
- None after typical rash appears and fever resolves
- Mean duration of illness is 6 days (4).
- If febrile seizures occur, they will cease after fever subsides and will not likely recur (4).
- Symptomatic reactivation in immunocompromised (1)

DIET

Encourage fluids.

PATIENT EDUCATION

- Parental reassurance that this is usually a benign, self-limited disease (1)
- There is no specific recommended period of exclusion from out-of-home care for affected children.
- Patient is viremic a few days prior to fever until time of defervescence and rash onset.

PROGNOSIS

- Course: acute, complete recovery without sequelae (1)
- Reactivation in immunocompromised patients is common (4).

COMPLICATIONS
- Febrile seizures
  - 13% patients with roseola (1,6)
  - Accounts for 1/3 of primary seizures in children <2 years old (1)
- Medication hypersensitivity syndromes (drug reaction with eosinophilia and systemic symptoms) (2)
- Reactivation can occur in transplant patients, HIV-1 infection, and other immunocompromised individuals (4).
- Meningoencephalitis occurs in immunocompetent and in immunosuppressed patients (4); poor association with multiple sclerosis (4)
- Pityriasis rosea (1)
- Possible association with progressive multifocal leukoencephalopathy (4)

REFERENCES

ADDITIONAL READING

CODES

ICD10
- B08.20 Exanthema subitum [sixth disease], unspecified
- B08.21 Exanthema subitum [sixth disease] due to human herpesvirus 6
- B08.22 Exanthema subitum [sixth disease] due to human herpesvirus 7

CLINICAL PEARLS

- Roseola infection should be suspected if an infant or young child presents with a high temperature without other clinical findings.
- As the fever abates, a macular rash will be seen on the trunk, with eventual spread to the face and extremities in 20% of patients.
- Roseola is a clinical diagnosis, and laboratory testing is not necessary for most children with classic presentation.
- For atypical presentations, complications, and immunocompromised hosts, several laboratory tools are available, including serologic testing for antibody, viral PCR testing, and viral culture.
- Infection is typically self-limiting and without sequelae.
- Usually, only symptomatic treatment is needed.
- Consider prophylaxis in patients undergoing bone marrow or stem cell transplant and receiving immunosuppressive therapy.
BASICS

DESCRIPTION
- Compression of rotator cuff tendons and subacromial bursa between the humeral head and the structures comprising the coracoacromial arch and proximal humerus
- Most common cause of atraumatic shoulder pain in patients >25 years of age
- Primary symptom is pain that is most severe when the arm is abducted between 60 and 120 degrees (the “painful arc”).
- Classically divided into three stages:
  - Stage I: acute inflammation, edema, or hemorrhage of the underlying tendons due to overuse (typically in those aged <25 years)
  - Stage II: progressive tendinosis that leads to partial rotator cuff tear along with underlying thickening or fibrosis of surrounding structures (commonly, ages 25 to 40 years)
  - Stage III: full-thickness tear (typically in patients age >40 years)

EPIDEMIOLOGY

Incidence
- Shoulder pain accounts for 1% of all primary care visits.
- Peak incidence of 25/1,000 patients per year occurs in patients aged 42 to 46 years.
- Impingement responsible for 18–74% of shoulder pain diagnoses

Prevalence
Prevalence of shoulder pain in general population ranges from ~7% to 30%.

RISK FACTORS
- Repetitive overhead motions (throwing, swimming)
- Glenohumeral joint instability or muscle imbalance
- Acromioclavicular arthritis or osteophytes
- Thickened coracoacromial ligament
- Shoulder trauma
- Increasing age
- Smoking

GENERAL PREVENTION
- Proper throwing and lifting techniques
- Proper strengthening to balance rotator cuff and scapula stabilizer muscles

DIAGNOSIS

HISTORY
- Gradual increase in shoulder pain with overhead activities (Sudden onset of sharp pain suggests a tear.)
Night pain is common, exacerbated by lying on the affected shoulder or sleeping with the affected arm above the head.

Anterolateral shoulder pain with overhead activities

May progress to weakness and decreased range of motion if shoulder is not used through full range of motion

**PHYSICAL EXAM**

Examine patient for atrophy/asymmetry. Observe how the patient takes off his or her shirt during exam.

- Neer impingement test: Examiner stabilizes the scapula and moves the affected upper extremity through a flexion arc. Positive is pain with flexion of the shoulder. Sensitivity: 78%. Specificity: 58% [1][A]

- Hawkins-Kennedy impingement test: Examiner places the arm in 90 degrees of forward flexion and then gently internally rotates the arm. End point for internal rotation is when the patient feels pain or when the rotation of the scapula is felt or observed by the examiner. Test is positive when patient experiences pain during the maneuver. Sensitivity: 74%. Specificity: 57% [1][A].

- Empty can test (supraspinatus): Examiner asks the patient to elevate and internally rotate the arm with thumbs pointing downward in the scapular plane. Elbow should be fully extended. Examiner applies downward pressure on upper surface of the arm. Test is positive when patient complains of pain with resistance. Sensitivity: 69%. Specificity: 62% [1][A].

- Lift-off test (subscapularis): Patient internally rotates the shoulder, placing the hand on ipsilateral buttock, then lifts hand off buttock against resistance. A tear in the subscapularis muscle produces weakness of this action. Sensitivity: 42%. Specificity: 97% [1][A].

- Drop-arm test: Patient fully elevates arm and then slowly reverses the motion. If the arm is dropped suddenly or the patient has extreme pain, the test is positive for a possible rotator cuff tear. Sensitivity: 21%. Specificity: 92% [1][A].

- Resisted external rotation: weakness suggestive of infraspinatus and/or teres minor tendon involvement

- Apprehension-relocation test for anterior glenohumeral joint instability: Have the patient supine or sitting; abduct the arm to 90 degrees and flex the patient’s elbow to 90 degrees; examiner slowly rotates the humerus (pushes hand posteriorly while patient resists, then anteriorly while the patient resists). If the patient becomes anxious or has apprehension from this maneuver, test is positive implying instability and risk for dislocation. If pain is present, rather than instability, consider impingement syndrome.

- Examine cervical spine to rule out cervical pathology as source of shoulder pain.

- Neurovascular exam of the upper extremity

**DIFFERENTIAL DIAGNOSIS**

- Labral injury

- Acromioclavicular arthritis (more common in older patients; positive cross-arm test—pain when affected arm is fully adducted across the chest in the horizontal plane)

- Adhesive capsulitis (rotator cuff tendonitis leads to decreased use and atrophy of rotator cuff muscles, followed by contracture; linked to diabetes and potentially prior trauma)

- Anterior shoulder instability (prior trauma; more common in patients <25 years old)

- Multidirectional instability

- Biceps tendonitis or rupture (Perform Speed and Yergason tests and look for visible or
palpable defect of biceps—“Popeye sign.”)
- Calcific tendonitis
- Cervical radiculopathy (spinal or foraminal stenosis, can test with Spurling maneuver)
- Glenohumeral arthritis (Evaluate with plain films.)
- Suprascapular nerve entrapment (Look for focal muscle atrophy of supra- or infraspinatus.)
- Traumatic rotator cuff tear

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Plain-film radiographs of the shoulder (three views): anteroposterior, axillary, scapular Y views
- Plain films may reveal:
  - Osteoarthritis of the acromioclavicular and glenohumeral joints
  - Superior migration of the humeral head (indicative of a large rotator cuff tear)
  - Cystic change of the humeral head and sclerosis of the inferior acromion (indicative of chronic rotator cuff disease)
  - Calcific tendonitis
- MRI is used to definitively assess rotator cuff tendinopathy, partial tears, and complete tears.
- MR arthrogram is preferred for labral pathology.
- Ultrasound is sensitive and specific for rotator cuff tears but is highly operator dependent.
- CT scan is preferred for bony pathology or for those unable to undergo MRI.

**Diagnostic Procedures/Other**
- Lidocaine injection test
  - Inject lidocaine into the subacromial space:
    - Repeat impingement tests; if pain is completely relieved and range of motion is improved, likely impingement syndrome (rather than cuff tear)
    - Allows for more accurate strength testing on physical examination:
      - If strength is intact, rule out rotator cuff tear.
      - If range of motion does not improve in any plane, more likely adhesive capsulitis
  - Some pain relief and improved range of motion occurs after lidocaine injection with
    - Glenoid labral tear
    - Capsular strain
    - Glenohumeral osteoarthritis
    - Glenohumeral instability
- A lack of any pain relief suggests other sources (i.e. cervical radiculopathy) or inappropriate placement of injection.

**Test Interpretation**
May have tendinosis, tendonitis, or muscle/tendon tear

**TREATMENT**
Pain control in combination with aggressive rehabilitation improves and fully resolves rotator cuff tendonitis in most patients.

**GENERAL MEASURES**
Rest
Ice or heat for symptom relief
Activity modification, with avoidance of aggravating activities, particularly overhead motions
Range of motion exercises
Rotator cuff and adjacent muscle strengthening to enhance stability and prevent further injuries

MEDICATION
First Line
NSAIDs or other analgesic, often for 6 to 12 weeks

ISSUES FOR REFERRAL
Failure of conservative treatment, persistent pain, weakness, or complete tear of rotator cuff

ADDITIONAL THERAPIES
- Supervised- or home-exercise regimens provide significant pain reduction and improve function (2)[A].
- Physical therapy is effective for short-term and long-term recovery of function (3)[A]:
  - Initial goal is to restore range of motion.
  - After pain resolves, gradually strengthen rotator cuff muscles in internal rotation, external rotation, and abduction.

SURGERY/OTHER PROCEDURES
- Steroid injections may have a significant benefit on pain and function in the short term but do not appear to have a significant long-term effect (4)[A].
- No evidence that surgery is superior to conservative management or that one surgical technique is superior to another for impingement syndrome (5)[A]
- Platelet-rich therapies for musculoskeletal soft tissue injuries are increasingly common.
  - No apparent effect of platelet-rich plasma injection during arthroscopic rotator cuff repair on overall retear rates or shoulder-specific outcomes
- Extracorporeal shock wave therapy is currently under study as an emerging treatment for calcific tendonitis.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture is potentially beneficial for reducing pain and improving function, particularly when used with physical therapy (6)[A].

ONGOING CARE

PATIENT EDUCATION
- Physical rehabilitation is necessary, both in conservative course of treatment (i.e., NSAIDs, physical therapy, home exercises) and in surgical intervention. An aggressive trial of rehabilitation should be encouraged prior to extensive testing or surgical intervention. Providing pain relief prior to beginning a program of physical therapy improves adherence and outcomes.
- Symptoms often recur if not fully addressed.

PROGNOSIS
• Variable, depends on underlying pathology
• Most patients improve with conservative management. Recovery can be slow.
• Patients with more severe symptoms—those with symptoms for >1 year—are less likely to respond well with conservative therapies.

COMPLICATIONS
• Progression of injury
• Tendon retraction in complete rotator cuff tear

REFERENCES

ADDITIONAL READING

CODES

ICD10
• M75.40 Impingement syndrome of unspecified shoulder
• M75.110 Incmpl rotatr-cuff tear/ruptr of unsp shoulder, not trauma
M75.120 Complete rotatr-cuff tear/rupt of unsp shoulder, not trauma

CLINICAL PEARLS

- Consider impingement syndrome in patients who engage in activities with repetitive overhead motions (e.g., swimming, throwing) who present with shoulder pain.
- Atraumatic shoulder pain in middle age often represents rotator cuff tendonitis.
- The supraspinatus tendon is most commonly affected in impingement syndrome.
- Neer and Hawkins tests specifically check for shoulder impingement.
- The empty can maneuver tests for weakness of supraspinatus muscle.
- The drop-arm test is specific for rotator cuff tear.
- Physical therapy over 6 to 12 weeks promotes return to function.
- Most patients with shoulder impingement respond well to conservative management.
BASICS
DESCRIPTION
- Inflammation or infection involving one or more salivary glands, most frequently involving the parotid, submandibular or sublingual glands.
- Can be acute, chronic, or acute on chronic in presentation. Depending on the number of glands involved, it may be characterized as unifocal or multifocal.
- Common types include infectious, obstructive (sialolithiasis), and autoimmune.
- Sialolithiasis is the cause of ~90% of all obstructive salivary gland diseases and is characterized by a painful swelling of the affected gland when eating, known as “mealtime syndrome.”
- The submandibular gland is more commonly affected (80–90% of cases) by sialolithiasis and infection than the parotid gland. Submandibular stones occur more commonly due to higher mucinous content of saliva, longer course of Wharton duct, slow salivary flow, and saliva flow against gravity.

EPIDEMIOLOGY
Incidence
- Predominant age: Peak incidence is 30 to 60 years.
- Most common in debilitated and dehydrated patients.
- 49% men and 51% women, average age 47.5 years; 82% submandibular stones and 18% parotid stones; 44% had a positive smoking history, and 20% of patients were taking diuretics.

Prevalence
- Salivary calculi can be found in 1.2% of the adult population.
- Only 5% of all cases occur in the pediatric population.
- In those with sialographic evidence of benign intraductal obstruction, the obstruction is caused by salivary calculi in >73% of cases.

ETIOLOGY AND PATHOPHYSIOLOGY
- Decreased salivary outflow from anticholinergics, dehydration, or radiation is thought to allow bacterial infection of salivary glands.
- Salivary calculi form by deposition of calcium phosphate. Predisposing factors include salivary stasis, retrograde bacterial contamination from the oral cavity, increased alkalinity of saliva, and physical trauma to salivary duct or gland.
- Gout is a systemic disease known to be associated with salivary stone development. In gout, sialoliths are composed of uric acid.
- Bacterial sialadenitis tends to be unifocal and is commonly caused by Staphylococcus aureus, Streptococcus viridans, Streptococcus pyogenes, Haemophilus influenzae, Escherichia coli, Pseudomonas aeruginosa, and group B streptococci (neonates and prepubescent children).
- Viral sialadenitis tends to be multifocal and is commonly caused by mumps, cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, and enteroviruses.
- Other common causes include radioiodine use, positive pressure ventilation use with
anesthesia, Sjögren syndrome, and sarcoidosis.

**Pediatric Considerations**
The two most common causes of sialadenitis in children are mumps and idiopathic juvenile recurrent parotitis.

**Genetics**
Polygenic cause, with several loci under investigation

**RISK FACTORS**
- Dehydration
- Anticholinergic use
- Antihistamine use
- Diuretic use
- Poor oral hygiene
- Malnutrition
- Head/neck radiation
- Tuberculosis (TB)
- HIV
- Failure to immunize (mumps)
- Gout
- Diabetes mellitus
- Hypothyroidism
- Renal failure
- Duct strictures
- Previous intraoral procedures

**GENERAL PREVENTION**
- Adequate hydration
- Maintain proper oral care and hygiene.
- Avoid antihistamines, anticholinergics, and other causes of xerostomia, especially if other risk factors are present.

**COMMONLY ASSOCIATED CONDITIONS**
- Postoperative dehydration
- Radiation-induced xerostomia
- Drug-induced xerostomia
- Sjögren syndrome
- Hypercalcemia

**DIAGNOSIS**

**HISTORY**
- Review immunization history.
- Obtain a complete history taking note of:
  - Alcoholism, bulimia, malnutrition
  - Recent dental work, oral surgery, anesthesia
– Radiation therapy, past malignancy
– TB or HIV exposure

- Acute onset of pain and swelling over the affected salivary gland, especially postprandial
- Dental pain, discharge, foul breath (halitosis), hypersalivation, and pain with chewing
- Fever, unintentional weight loss
- Xerostomia

**PHYSICAL EXAM**
- Visual inspection of the glands.
- Bimanual exam of oral cavity palpating all salivary glands, floor of mouth, tongue, and neck to assess symmetry, tenderness, induration, edema, presence of stones, lymphadenopathy, and the number of glands involved.
- Examine duct openings for purulent discharge and presence of saliva.
- Gently palpate gland to express normal, thin, absent, or reduced amounts of saliva; assess for bubbling appearance or purulent drainage.
- Examine eyes for interstitial keratitis.
- Evaluation of facial nerve (CN VII) function, which is at high risk of being compromised if parotid gland is involved.
- Note lingual papillary atrophy and/or loss of tooth enamel.

**Pediatric Considerations**
Stones in children are traditionally smaller in size, within the duct distally, and present with a shorter symptom duration. Thus, ultrasound with sialendoscopy is considered diagnostic and therapeutic.

**DIFFERENTIAL DIAGNOSIS**
- Acute bacterial parotitis
- Chronic bacterial parotitis
- Idiopathic juvenile recurrent parotitis
- Dental abscess
- Mumps
- TB
- HIV (in pediatric populations)
- EBV, CMV, enteroviruses
- Tularemia
- Cystic fibrosis
- Lupus
- Sjögren syndrome
- Alcoholism
- Bulimia
- Hypothyroidism
- Pleomorphic adenoma
- Lymphoma
- Sarcoidosis
- Collagen vascular disease
- Metal poisoning

**DIAGNOSTIC TESTS & INTERPRETATION**
Initial Tests (lab, imaging)
- Consider complete blood count, rarely electrolytes.
- Culture and sensitivity of any expressed pus.
- When considering sialolithiasis as a primary diagnosis, initial imaging with ultrasound can be done as it is able to detect up to 90% of stones 1–3 mm or larger (1)[C].
- CT scan with IV contrast is more sensitive than sonography, however one must consider the amount of radiation exposure for each patient (2)[C].
- MR sialography is a noninvasive way to determine ductal structure in patients with an inconclusive ultrasound and persistent symptoms.
- Sonopalpation (concurrent ultrasound with transoral palpation) proved to have a sensitivity and specificity of 96.6% and 90% in finding a calculus (2)[B].

Follow-Up Tests & Special Considerations
- If autoimmune process is suspected, consider ordering appropriate labs, such as autoantibody titers: Sjögren syndrome A (SS-A) and Sjögren syndrome B (SS-B), rheumatoid factor (RF), and antinuclear antibodies (ANAs). Erythrocyte sedimentation rate (ESR) may also be conducted (3)[C].
- Salivary gland biopsy
- Consider serial CT scans with contrast to evaluate disease resolution.
- Ultrasound can identify indicators of persistent obstruction in patients undergoing sialolithotomy.

Diagnostic Procedures/Other
- Sialography to evaluate sialolithiasis and other obstructive lesions
- Sialendoscopy to find and remove sialoliths. In one study, sialendoscopy confirmed 221 (79%) parotid and 812 (93%) submandibular stones (4)[A].
- One study revealed that sonography, cone beam CT, and sialendoscopy all had excellent specificity and positive predictive value in diagnosing stones (2)[B].
- In a retrospective study of 2,052 patients, ultrasound revealed 95% of false-negative findings to be positive for ductal dilation in the major salivary glands. 73.1% of the stones located in the distal part of the duct; unable to be detected on ultrasound were visualized and accessed by a sialendoscope.
- When sialendoscopy fails, a novel ultrasound-guided needle localization approach has been proposed.
- Technetium-99m pertechnetate scintigraphy showed decreased gland excretion and decreased uptake in patients with sialolithiasis.

Test Interpretation
In chronic sialadenitis, loss of acini, fibrosis, and periductal lymphocytosis are evident; degree indicates chronicity.

TREATMENT
GENERAL MEASURES
- Maintain hydration.
- Apply warm compresses with massage.
Maintain good oral hygiene.
Antibiotics if indicated by diagnosis

**MEDICATION**

**First Line**
- Antistaphylococcal penicillins (nafcillin, dicloxacillin) are indicated in areas where methicillin-resistant S. aureus (MRSA) is not predominant.
- Penicillin-allergic: Use clindamycin 300 mg PO q8h.
- Gram negative: 3rd-generation cephalosporin or fluoroquinolone
- Anaerobic: metronidazole or clindamycin
- Antibiotic coverage should be narrowed once culture and sensitivity are available.
- Continue antibiotic therapy for 10 to 14 days.

**Second Line**
- 1st-generation cephalosporin (cephalexin or cefazolin) or clindamycin is also indicated for empiric coverage.
- If MRSA, then vancomycin

**ISSUES FOR REFERRAL**
In the case of poor dentition and dental abscess, refer patient to a dentist.

**ADDITIONAL THERAPIES**
In the case of chronic sialadenitis with strictures, consider sialostent placement.

**SURGERY/OTHER PROCEDURES**
- Submandibular stones found in the anterior floor of the mouth can be excised intraorally (sialodochoplasty), whereas those in the hilum require gland excision. Parotid stones usually require parotidectomy (3)[A].
- Good results in patient symptom relief, quality of life, and safety have been reported in sialadenitis and sialolithiasis using sialendoscopy (3,4,5)[A]. However, one study revealed a complication rate of 3.23%. Complications include strictures, ranulas, and lingual nerve injury.
- A combined approach using limited intraoral incision with sialendoscopy has shown an 87% success rate.
- Incision and drainage of parotid abscess is indicated after failing 3 to 5 days of medical management.
- Sialoliths and stenoses can be successfully treated by radiologically or fluoroscopically controlled or sialendoscopically based methods in ~80% of cases. Extracorporeal shock wave lithotripsy (ESWL) is successful in up to 50% of cases.
- Transoral duct slitting is an important method for extraparenchymal submandibular stones, with a success rate of 90%.
- Sialolithotomy with sialendoscopy can now be successfully performed robotically (6)[B].
- Recent evidence shows that larger stones can be successfully and safely treated with holmium:YAG laser lithotripsy.

**Pediatric Considerations**
The most effective diagnostic and therapeutic modality for children with sialadenitis is sialendoscopy with stone retrieval (7)[B].
COMPLEMENTARY & ALTERNATIVE MEDICINE
Consider lemon drops or other sialogogues to promote salivation. In one study, postoperative use of sialogogues nearly halved rates of sialadenitis (3)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Parotid abscess
- Sepsis
- Inability to tolerate PO intake
- Airway, breathing, or circulation become compromised
- Check vital signs, with particular attention to blood pressure because patient may be septic secondary to abscess formation.
- Nursing responsibilities may include ensuring excellent oral hygiene and avoiding administration of drugs that cause decreased production or flow of saliva.
- Discharge criteria
  - Exclude abscess or sepsis.
  - Ensure ability to tolerate PO intake.
  - Stable vital signs

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Provide regular follow-up visits for patients with chronic sialadenitis.
- Avoid prescribing medications that cause xerostomia.

Patient Monitoring
Continue to monitor patients with chronic sialadenitis because decreased salivary gland function due to fibrosis and loss of acini can lead to acute exacerbations.

DIET
- Avoid sialogogues during acute attacks.
- Maintain adequate hydration on an outpatient basis.

PATIENT EDUCATION
- Educate patients on maintaining excellent oral hygiene.
- Educate patients on maintaining good hydration.

PROGNOSIS
- Generally excellent, with acute symptoms resolving in about a week with appropriate treatment
- Patients with autoimmune etiology may have prolonged course due to systemic involvement.

COMPLICATIONS
Abscess, dental caries, recurrent sialadenitis, facial nerve impingement, Ludwig angina

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- K11.5 Sialolithiasis
- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis

**CLINICAL PEARLS**

- Sialadenitis is associated with conditions that predispose patient to xerostomia.
- Sialadenitis occurs in debilitated patients who lack ability to control hydration.
- Mainstay of treatment is hydration, good oral hygiene, sialogogues, and possible surgical excision.
- Many cases are now being successfully and safely treated with ultrasound followed by sialendoscopy.
BASICS

DESCRIPTION
- Infection caused by any serotype of the bacterial genus Salmonella, a gram-negative anaerobic bacillus
- Nontyphoidal Salmonella typically causes gastroenteritis via foodborne infection and sporadic outbreaks; less commonly causes infection outside the gastrointestinal (GI) tract
- Clinical syndromes
  - Enteric fever (see “Typhoid Fever”)  
  - Nontyphoidal gastroenteritis
    - Chronic carrier state (>1 year)
  - Nontyphoidal invasive disease
    - Bacteremia
      - Endovascular complications
      - Localized infection outside GI tract

Geriatric Considerations
Patients >65 years old have increased risk of invasive disease with bacteremia and endovascular complications due to comorbidities (atherosclerotic endovascular lesions, prostheses, etc.) that increase risk of bacterial seeding.

Pediatric Considerations
Neonates (<3 months) are more susceptible to invasive disease and complications.

EPIDEMIOLOGY

Incidence
- Global incidence of nontyphoidal Salmonella enteritidis estimated to be ~94 million per year
  - Wide variation by region from 40 to 3,980 estimated cases per 100,000
- Global incidence of invasive nontyphoidal Salmonella infection estimated to be 2 to 6.5 million in 2010
  - Wide variation by region from 0.8 to 227 estimated cases per 100,000
- Most commonly identified foodborne illness in the United States and a common cause of traveler’s diarrhea. Annual incidence in the United States is 15 illnesses per 100,000.
- Second most common bacteria isolated from stool cultures in diarrheal illness (following Campylobacter) in the United States
- Highest incidence in children <5 years old
- Hospitalization rates higher in patients >50 years old
- Peak frequency: July to November

ETIOLOGY AND PATHOPHYSIOLOGY
- Salmonella enterica
Most pathogenic species in humans
- 2,500 different serotypes

**Etiology**
- ~95% of cases are foodborne.
- Other cases (5%) are due to direct or indirect fecal–oral contact with animals or human carriers.
- Iatrogenic contamination (e.g., blood transfusion, endoscopy) is rare.

**Pathophysiology**
- Typical infectious dose in immunocompetent patients is ingestion of 1 million bacteria.
- Bacteria ingested invade the distal ileal and proximal colonic mucosa to produce an inflammatory and cytotoxic response.
- Bacteria can enter the mesenteric lymphatic system and then the systemic circulation to cause disseminated/invasive disease.

**RISK FACTORS**
- Recent travel to underdeveloped nations
- Consumption of undercooked meat, egg, or unpasteurized dairy products. Nonanimal products have also been implicated in outbreaks.
- Contact with live reptiles or poultry
- Contact with human carrier (Salmonella fecal shedding)
- Impaired gastric acidity: H$_2$ receptor blockers, antacids, proton pump inhibitors (PPIs), gastrectomy, achlorhydria, pernicious anemia, infants
- Recent antibiotic use
- Reticuloendothelial blockade: sickle cell disease, malaria, bartonellosis
- Immunosuppression: HIV, diabetes, corticosteroid or other immunosuppressant use, chemotherapy
- Iron overload, chronic granulomatous disease
- Age <5 years or >50 years

**GENERAL PREVENTION**
- Proper hygiene in production, transport, and storage of food (e.g., refrigeration during food storage and thoroughly cooking food prior to consumption)
- Control of animal reservoirs: Avoid contact with high-risk animals, feces, and polluted waters.
- Hand hygiene
- CDC tracks outbreaks (http://www.cdc.gov/salmonella/).

**COMMONLY ASSOCIATED CONDITIONS**
- Gastroenteritis
- Bacteremia: immunocompromised or patients with underlying disease (e.g., cholelithiasis, prostheses)
- Osteomyelitis: higher incidence in sickle cell disease
- Abscesses: higher incidence with malignant tumors
- Reactive arthritis

**DIAGNOSIS**
**HISTORY**
- Salmonella infections are typically asymptomatic or result in mild, self-limited gastroenteritis.
- Exposure history: travel; contact with infected human, reptile, or poultry; improper food preparation
- Host factors: age, immune status, other risk factors
- Symptoms typically begin 12 to 72 hours after ingestion and resolve within 4 to 10 days.
- Acute uncomplicated illness
  - Sudden onset of diarrhea
  - Vomiting is infrequent.
  - Abdominal cramping
  - Headache
  - Myalgias
  - Fever

**PHYSICAL EXAM**
- Fever
- Evidence of hypovolemia
- Abdominal tenderness
- Heme-positive stool in some patients
- Hepatosplenomegaly in some patients

**DIFFERENTIAL DIAGNOSIS**
- Viral gastroenteritis
- Bacterial enteritis due to other organisms
- Pseudomembranous colitis
- Inflammatory bowel disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Gastroenteritis
  - Stool culture for Salmonella, Escherichia coli, Shigella, and Campylobacter (1)[C] (Optimal specimen is a diarrheal stool sample.)
  - Indications for stool culture include:
    - Severe diarrhea (≥6 loose stools daily) (1)[C]
    - Diarrhea ≥1 week in duration (1)[C]
    - Fever (1)[C]
    - Diarrhea containing blood or mucous (1)[C]
    - Multiple cases suggesting an outbreak (1)[C]
  - Fecal leukocytes: positive
  - Blood cultures are warranted in:
    - Infants <3 months
    - People of any age with signs of septicemia or other systemic manifestations of infection
    - Cases where enteric fever is suspected
    - Immunocompromised patients
- Bacteremia
  - Blood cultures if febrile (1)[C]
  - Stool cultures: may also be positive (1)[C]
– Culture CSF if patient is <3 months of age with positive blood culture.

Endovascular infection
– Consider angiography in bacteremic patients >50 years of age if aortic or vascular source is suspected (2)[A].

Local infections
– Wound culture
– Consider CT or MRI for soft tissue or bone infections (3)[C].

Chronic carrier state
– Stool culture positive for >1 year (3)[C]
– Urine culture may be positive in chronic carriers.

Follow-Up Tests & Special Considerations
– Look for other causes in diarrhea lasting >14 days.
– Asymptomatic excretion of Salmonella may occur for weeks after infection; follow-up fecal cultures are routinely not indicated for patients with uncomplicated gastroenteritis (2,3)[C].
– Follow-up blood cultures suggested for patients with bacteremia (3)[C]

Test Interpretation
Intestinal biopsies (if taken) may show mucosal ulceration, hemorrhage, and necrosis seen on along with reticuloendothelial hypertrophy/hyperplasia.

TREATMENT
– Treatment is supportive for nonsevere nontyphoidal Salmonella gastroenteritis in immunocompetent patients between 12 months and 50 years of age. The illness is typically self-limited. There is no proven benefit for treatment of mild disease. Treatment can suppress the host immunologic response. Higher rates of relapse have also been reported and there is the potential to extend asymptomatic carriage (1)[C].
– Consider antibiotics in immunocompetent hosts with severe diarrhea, high fever, or those requiring hospitalization (1)[C].
– Patients at increased risk of bacteremia benefit from antibiotics:
  – Infants <12 months of age (1)[C]
  – Patients >50 years old (risk particularly increases after age 65 years) (1,3)[C]
  – HIV-infected patients
  – Patients with hemoglobinopathies, atherosclerotic lesions, and prosthetic valves, grafts, or joints or any immunosuppressed state (1)[C],(2)[A],(3)[C]
– Chronic carriage of nontyphoidal Salmonella
  – 4 to 6 weeks of antimicrobial therapy
  – Prophylactic therapy in immunocompromised patients (2)[A]

GENERAL MEASURES
– Hydration and electrolyte replacement
– Hand washing and barrier precautions for inpatients
– Avoid antimotility drugs in patients with fever or dysentery. Antimotility drugs may increase contact time of the enteropathogen in the gut mucosa (1)[C].

MEDICATION
**First Line**

- **Gastroenteritis, uncomplicated**: No specific medications are necessary; supportive care (1)[A].
- **Gastroenteritis, complicated (due to illness severity or host risk factors such as immunocompromised)**
  - Adults (Treat for 14 days if immunocompromised.)
    - Levofoxacin (or other fluoroquinolone) 500 mg/day PO for 7 to 10 days (1)[C] or
    - Trimethoprim-sulfamethoxazole: 160/800 mg PO BID for 7 to 10 days or
    - Amoxicillin: 500 mg PO TID for 7 to 10 days or
    - Cefixime: 400 mg orally once or twice daily or
    - Azithromycin: 500 mg/day PO for 7 days or 1 g, followed by 500 mg daily for 5 to 7 days (1)[C]
  - Children
    - Ceftriaxone: 100 mg/kg/day IV or IM in 2 equally divided doses for 7 to 10 days (1)[C] or
    - Azithromycin: 20 mg/kg PO for first dose and then 10 mg/kg/day for subsequent doses daily for 7 days (1)[C]
  - HIV patients
    - Increased duration (range of 2 to 6 weeks) of antimicrobial therapy and/or zidovudine may decrease relapse (2)[C].

- **Bacteremia**: Due to resistance trends, treat life-threatening infections in adults with a fluoroquinolone or a 3rd-generation cephalosporin until susceptibilities are determined (2)[A].
  - Adults
    - Ciprofloxacin (or other fluoroquinolone): 400 mg IV BID for 10 to 14 days plus
    - Ceftriaxone: 1 to 2 g/day IV for 10 to 14 days or
    - Cefotaxime: 2 g IV q8h for 10 to 14 days
  - Children
    - Ampicillin: 200 mg/kg/day in 4 divided doses for 10 to 14 days or
    - Trimethoprim-sulfamethoxazole: 8 to 12 mg/kg/day of trimethoprim component in 2 divided doses for 10 to 14 days or
    - Ceftriaxone: 50 to 75 mg/kg/day (max 1 g) once per day for 10 to 14 days

- **Localized infection (e.g., septic arthritis, osteomyelitis, cholangitis, and pneumonia); surgical drainage or débridement in addition to a minimum of 3 weeks of antimicrobial therapy**
  - In sustained bacteremia, prolonged local infection, or immunocompromised patients, give antibiotics PO for 4 to 6 weeks (2)[A].

- **Chronic carrier state (shedding >1 year duration)**
  - Amoxicillin: 1 g PO TID for 12 weeks or
  - Trimethoprim-sulfamethoxazole 160 mg/800 mg PO BID for 12 weeks or
  - Ciprofloxacin: 500 mg PO BID for 4 weeks or
  - Levofoxacin 500 mg/day for 4 weeks or
  - Norfloxacin 400 mg PO BID for 4 weeks if gallstones are present

**ALERT**

*Antimicrobial resistance*

- Strains resistant to ampicillin, chloramphenicol, and trimethoprim-sulfamethoxazole have been reported.
- Fluoroquinolone resistance is increasing, perhaps due to increasing use in livestock.
- Extended-spectrum cephalosporin resistance has been reported with increasing frequency.
Second Line
- Aztreonam is an alternative agent that may be useful in patients with multiple allergies or if the organism demonstrates an unusual resistance pattern (2)[A].
- Fluoroquinolones are now routinely given to children for 5 to 7 days in areas of the world where multidrug-resistant Salmonella typhi is common (2)[A].

SURGERY/OTHER PROCEDURES
- Surgical excision and drainage for infected tissue sites, followed by a minimum of 3 weeks of antibiotic therapy.
- If biliary tract disease is present, a preoperative 10- to 14-day course of parenteral antibiotics is recommended prior to cholecystectomy.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Asymptomatic shedding of Salmonella may occur for weeks after infection. Follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis. Requirements may differ during a Salmonella outbreak.
- Criteria may vary by state and local regulations. Some public health departments require negative stool cultures for health workers and food handlers prior to returning to work. Shedding may last 4 to 8 weeks.
- Serotyping of isolates can be performed at public health laboratories.

DIET
Easily digestible foods

PATIENT EDUCATION
- Meticulous hand hygiene; caution handling raw meat, poultry, and eggs.
- Fruits and vegetables should be thoroughly washed prior to consumption.
- Thoroughly cooking meats eliminates Salmonella.
- Caution when handling animals with high fecal carriage rates.
- [www.cdc.gov/salmonella/general/prevention.html](http://www.cdc.gov/salmonella/general/prevention.html)

PROGNOSIS
- Most cases of Salmonella gastroenteritis are self-limited and have an excellent prognosis.
- Increased mortality is seen in the young (<3 months), elderly (>65 years), and immunocompromised.
- Increased mortality is seen with bacteremia and other invasive infections.
- Mortality is increased in multidrug-resistant strains.

COMPLICATIONS
- Toxic megacolon, hypovolemic shock, metastatic abscess formation, endocarditis, infectious endarteritis, meningitis, septic arthritis, reactive arthritis, osteomyelitis, pneumonia, appendicitis, cholecystitis
REFERENCES

ADDITIONAL READING

SEE ALSO
- Gastroenteritis; Typhoid Fever

CODES
ICD10
- A02.9 Salmonella infection, unspecified
- A02.0 Salmonella enteritis
- A02.1 Salmonella sepsis

CLINICAL PEARLS
- Nontyphoidal Salmonella infection is typically a foodborne infection associated with a self-limited gastroenteritis.
- Clinical syndromes include gastroenteritis, bacteremia, endovascular infection, localized infection outside the GI tract, and a chronic carrier state.
- Those at greatest risk of complications from Salmonella infection include the young, the elderly, and immunocompromised patients.
- Uncomplicated gastroenteritis in healthy patients can be treated with supportive care.
- Antibiotics should be used in infants, the elderly, immunocompromised patients, and for invasive infections such as bacteremia outside the GI tract.
SARCOIDOSIS
Donnah Mathews, MD

BASICS
DESCRIPTION
- Sarcoidosis is a noninfectious, multisystem, granulomatous disease of unknown cause, commonly affecting young and middle-age adults.
  - Frequently presents with bilateral hilar adenopathy, pulmonary infiltrates, ocular or skin lesions
  - In ~50% of cases, it is diagnosed in asymptomatic patients with abnormal chest x-rays (CXR).
  - Almost any organ may be involved.
- System(s) affected: primarily pulmonary but also cardiovascular, gastrointestinal, hematologic/lymphatic, endocrine, renal, neurologic, dermatologic, ophthalmologic, musculoskeletal
- Synonym(s): Löfgren syndrome (erythema nodosum [EN], hilar adenopathy, fever, arthralgias); Heerfordt syndrome (uveitis, parotid enlargement, facial palsy, fever); Besnier-Boeck disease; Boeck sarcoid; Scheuermann disease (1,2)

EPIDEMIOLOGY
Incidence
Estimated 6/100 person-years (1)

Prevalence
- Estimated 10 to 20/100,000 persons
- 11/100,000 annual incidence rate for women (2)
- Usually occurs in younger persons, although in a single center medical record review in Minnesota, the peak age of incidence for women was 50 to 69 years and for men 40 to 59 years (3)
- Rare in children (1,4)
- In the United States, the highest prevalence is in the Northeast (2).

ETIOLOGY AND PATHOPHYSIOLOGY
- Despite extensive research, etiology is unknown
- Thought to be due to exaggerated cell-mediated immune response to unknown antigen(s)
- In the lungs, the initial lesion is CD4+ T-cell alveolitis, causing noncaseating granulomata, which may resolve or may undergo fibrosis.
- “Immune paradox” with affected organs showing an intense immune response and yet anergy exists elsewhere (5)[C]

Genetics
- Reports of familial clustering, with genetic linkage to a section within MHC on short arm of chromosome 6
- 3 to 4 times more common in African Americans
- Although worldwide in distribution, increased prevalence in Scandinavians, Japanese, African
Americans, and women
- In Northern Europe, 5 to 40 cases per 100,000 persons. In Black Americans, 35 cases per 100,000 persons; in Caucasian Americans, 11 cases per 100,000 persons (1)

**RISK FACTORS**
Exact etiology and pathogenesis remain unknown.

**GENERAL PREVENTION**
None

**COMMONLY ASSOCIATED CONDITIONS**
None

---

**DIAGNOSIS**

**HISTORY**
- Patients may be asymptomatic.
- Patients may have nonspecific complaints, such as the following:
  - Nonproductive cough
  - Shortness of breath
  - Fever
  - Night sweats
  - Weight loss
  - General fatigue
  - Eye pain
  - Chest pain/palpitations
  - Skin lesions
  - Polyarthritis
  - Renal calculi
  - Facial droop due to Bell palsy
  - Encephalopathy, seizures, hydrocephalus (rare)
  - Patients >70 years old more likely to have systemic symptoms

**PHYSICAL EXAM**
- Many patients have a normal physical exam.
- Lungs may reveal wheezing/fine interstitial crackles in advanced disease.
- ~30% of patients have extrapulmonary manifestations (5), which may include the following:
  - Uveitis
  - Other eye findings: conjunctival nodules, lacrimal gland enlargement, cataracts, glaucoma, papilledema
  - Cranial nerve palsies
  - Salivary gland swelling
  - Lymphadenopathy
  - Arrhythmias
  - Hepatosplenomegaly
  - Polyarthritis
  - Rashes (5)
Maculopapular of nares, eyelids, forehead, base of neck at hairline, and previous trauma sites
Waxy nodular of face, trunk, and extensor surfaces of extremities
Plaques (lupus pernio) of nose, cheeks, chin, and ears
EN (component of Löfgren syndrome)
Atypical lesions

**DIFFERENTIAL DIAGNOSIS**
- Sarcoidosis is a diagnosis of exclusion.
- Infectious granulomatous disease, such as tuberculosis and fungal infections
- Hypersensitivity pneumonitis
- Lymphoma
- Other malignancies associated with lymphadenopathy
- Berylliosis (5)

**DIAGNOSTIC TESTS & INTERPRETATION**
No definitive test for diagnosis, but diagnosis is suggested by the following:
- Clinical and radiographic manifestations
- Exclusion of other diagnoses
- Histopathologic detection of noncaseating granulomas

**Initial Tests (lab, imaging)**
- CBC: Anemia/leukopenia ± eosinophilia can be seen.
- Hypergamma globulinemia can exist.
- LFTs: Abnormal liver function and increased alkaline phosphatase can be encountered with hepatic involvement.
- Calcium: Hypercalciuria occurs in up to 10% of patients, with hypercalcemia less frequent.
- Serum ACE elevated in >75% of patients but is not diagnostic or exclusionary
  - Drugs may alter lab results: Prednisone will lower serum ACE and normalize gallium scan. ACE inhibitors will lower serum ACE level.
  - Disorders may alter lab results: Hyperthyroidism, diabetes. tuberculosis, other cancers may also increase serum ACE level.
- CXR or CT scan may reveal granulomas/hilar adenopathy. Routine CXRs are staged using Scadding classification.
  - Stage 0 = normal
  - Stage 1 = bilateral hilar adenopathy alone
  - Stage 2 = bilateral hilar adenopathy + parenchymal infiltrates (primarily upper lobes)
  - Stage 3 = parenchymal infiltrates (primarily upper lobes) with shrinking hilar adenopathy
  - Stage 4 = parenchymal infiltrates with volume loss, bronchiectasis, calcification, or cyst formation (4)(5)
- Chest CT scan may enhance appreciation of lymph nodes.
- High-resolution chest CT scan may reveal peribronchial disease.
- Gallium scan will be positive in areas of acute disease/inflammation but is not specific.
- Positron emission tomography (PET) scan can indicate areas of disease activity in lungs, lymph nodes, and other areas of the body but does not differentiate between malignancy and sarcoidosis.
- Cardiac PET scan may detect cardiac sarcoidosis (1)(5).
Serum amyloid A and adenosine deaminase have been found to be elevated with sarcoidosis but are not clinically used due to low sensitivity and specificity (6)[C].

**Diagnostic Procedures/Other**

- Pulmonary function tests (PFTs) may reveal restrictive pattern with decreased carbon monoxide diffusing capacity (DLCO).
- Characteristically in active disease, bronchoalveolar lavage fluid has an increased CD4-to-CD8 ratio.
- Ophthalmologic examination may reveal uveitis, retinal vasculitis, or conjunctivitis.
- ECG
- Tuberculin skin test
- Biopsy of lesions should reveal noncaseating granulomas.
- If lungs are affected, bronchoscopy with biopsy of central and peripheral airways is helpful. Endobronchial US (EBUS)–guided transbronchial needle aspiration may potentially have a better diagnostic yield (4)[C].
- Kveim test (ongoing research): Suspension of sterilized splenic cells from a patient with sarcoidosis is injected in an intradermal skin test to evoke a sarcoid granulomatous response over 3 weeks, similar to a tuberculin skin test.

**ALERT**

If signs indicate Löfgren syndrome (acute sarcoid with bilateral hilar lymphadenopathy, EN, and diffuse arthritis/arthritis), it is not necessary to perform a biopsy because prognosis is good with observation alone, and biopsy would not change management.

**Test Interpretation**

Noncaseating epithelioid granulomas without evidence of fungal/mycobacterial infection

**TREATMENT**

- Many patients undergo spontaneous remission. It is difficult to assess disease activity and severity, however, making it challenging to develop guidelines.
- No treatment may be necessary in asymptomatic individuals, but treatment may be needed for specific indications, such as cardiac, CNS, renal, or ocular involvement.
- No treatment is indicated for asymptomatic patients with stage I to III radiographic changes with normal/mildly abnormal lung function, although close follow-up is recommended.
- Treatment of pulmonary and skin manifestations is done on the basis of impairment. The symptoms that necessitate systemic therapy remain controversial.
  - Worsening pulmonary symptoms
  - Deteriorating lung function
  - Worsening radiographic findings (7)[B]

**MEDICATION**

Systemic therapy is clearly indicated for hypercalcemia, cardiac disease, neurologic disease, and eye disease not responding to topical therapy. Most patients with pulmonary sarcoidosis do not require treatment with medications because many are asymptomatic or have a spontaneous remission.
First Line
- There is no FDA-approved treatment specifically for sarcoidosis.
- Systemic corticosteroids in the symptomatic individual (dyspnea, cough, hemoptysis) or in the individual with worsening lung function or radiographic findings
  - The optimal dose of glucocorticoids is not known.
  - Prior to initiating glucocorticoids, must exclude tuberculosis
  - Usually prednisone initially, 0.3 to 0.6 mg/kg ideal body weight (20 to 40 mg/day) for 4 to 6 weeks
  - If stable, taper by 5 mg/week to 10 to 20 mg/day over the next 6 weeks.
  - If no relapse, 10 to 20 mg/day for 8 to 12 months
  - Relapse is common.
  - Higher doses (80 to 100 mg/day) may be warranted in patients with acute respiratory failure and cardiac, neurologic, or ocular disease.
- In patients with skin disease, topical steroids may be effective.
- Inhaled steroids (budesonide 800 to 1,600 μg BID) may be of some clinical benefit in early disease with mild pulmonary symptoms.
  - Contraindications: patients with known problems with corticosteroids
  - Precautions: careful monitoring in patients with diabetes mellitus and/or hypertension
  - Significant possible interactions: Refer to the manufacturer’s profile of each drug (1,5,7)[B].

Second Line
- All alternative agents to glucocorticoids carry substantial risk for toxicity, including myelosuppression, hepatotoxicity, and opportunistic infection. Prior to utilizing these medications, it is important to assess for steroid compliance, comorbid disease, or other complicating factors contributing to steroid failure.
- Methotrexate: initially 7.5 mg/week, increasing gradually to 10 to 15 mg/week
- Azathioprine: generally a supplement to prednisone in an attempt to lower steroid doses
- Leflunomide
- Mycophenolate
- Use of immunosuppressants, such as methotrexate or azathioprine, will require regular monitoring of CBC and LFTs.
- Antimalarial agents, such as chloroquine or hydroxychloroquine, have been trialed
- Tumor necrosis factor antagonists, such as infliximab, have been useful in refractory cases (1,7)[C].

ISSUES FOR REFERRAL
May be followed by a pulmonologist, with referrals to other specialists as dictated by involvement of other organ systems; if requiring a second-line therapy, should be followed by a specialist.

SURGERY/OTHER PROCEDURES
Lung transplantation in severe, refractory cases; long-term outcomes are unknown.

COMPLEMENTARY & ALTERNATIVE MEDICINE
None known to be effective
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
There is limited data on indications for the specific tests and optimal frequency of monitoring of disease activity. Suggestions follow.

Patient Monitoring
- Patients on prednisone for symptoms should be seen q1–2mo while on therapy.
- Patients not requiring therapy should be seen regularly (q3mo) for at least the first 2 years after diagnosis, obtaining a thorough history and physical exam, laboratory testing tailored to sites of disease activity, PFTs, and ambulatory pulse oximetry.
- If active disease
  - Every 6 to 12 months, obtain ophthalmologic exam if on hydroxychloroquine.
  - Annually, CBC, creatinine, calcium, LFTs, ECG, 25-hydroxy vitamin D and 1,25 dihydroxy vitamin D, CXR, ophthalmologic examination
- Other testing per individual patient’s symptoms, including HRCT, echocardiogram, Holter monitoring, urinalysis (UA), thyroid-stimulating hormone (TSH), bone density, MRI of brain
- The serum ACE level is used by some physicians to follow the disease activity. In patients with an initially elevated ACE level, it should fall toward normal while on the therapy or when the disease resolves.
- If inactive disease, follow annually with history and physical exam, PFTs, ambulatory pulse oximetry, CBC, creatinine, calcium, liver enzymes, 1,25 dihydroxy vitamin D, ECG, and ophthalmologic exam.

DIET
No special diet

PATIENT EDUCATION
- The American Lung Association: [www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuimp6MCFQxW2godISFepQ](http://www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuimp6MCFQxW2godISFepQ)

PROGNOSIS
- 50% of patients will have spontaneous resolution within 2 years.
- 25% of patients will have significant fibrosis, but no further worsening of the disease after 2 years.
- 25% of patients (higher in some populations, including African Americans) will have chronic disease.
- Patients on corticosteroids for >6 months have a greater chance of having chronic disease.
- Overall death rate: <5%
- Rate of hospitalization is higher among patients with sarcoidosis than without sarcoidosis (8 [B].

COMPLICATIONS
- Patients may develop significant respiratory involvement, including cor pulmonale.
- Pulmonary hemorrhage from infection with aspergillosis in the damaged lung is possible.
- Other organs, especially the heart (congestive heart failure, arrhythmias), eyes (rarely
blindness), and CNS, can be involved with serious consequences. Cardiac, ocular, and CNS involvement usually manifest early in patients with these complications of the disease.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- D86.9 Sarcoidosis, unspecified
- D86.0 Sarcoidosis of lung
- D86.86 Sarcoid arthropathy

CLINICAL PEARLS

- Sarcoidosis is a noninfectious, multisystem, granulomatous disease of unknown cause, typically affecting young and middle-age adults.
- Any organ can be affected.
- Diagnosis is based on clinical findings, exclusion of other disorders, and pathologic detection of noncaseating granulomas.
- Most patients do not need systemic treatment, and the disease resolves spontaneously; a few will have life-threatening progressive organ dysfunction.
SCABIES
Ryan J. Dono, MD

BASICS

DESCRIPTION
● A contagious parasitic infection of the skin caused by the mite Sarcoptes scabiei, var. hominis
● Typically, a clinical diagnosis based on history and physical exam
● System(s) affected: skin/exocrine

EPIDEMIOLOGY

Incidence
Predominant age: children, sexually active young adults, and the elderly

Prevalence
Prevalence varies substantially worldwide but is more common in resource-poor settings (1):
● More prevalent in areas of overcrowding and in developing countries, particularly tropical climates
● Added to World Health Organization list of neglected tropical diseases in 2013

ETIOLOGY AND PATHOPHYSIOLOGY
● S. scabiei, var. hominis
  – An obligate human parasite
  – Primarily transmitted by prolonged human-to-human direct skin contact
  – Infrequently transmitted via fomites (e.g., bedding, clothing, or furnishings)
● Female mite lays eggs in burrows in the stratum corneum and epidermis.
● Itching is caused by a delayed type IV hypersensitivity reaction to the mite saliva, eggs, or excrement.

RISK FACTORS
● Prolonged skin-to-skin contact (e.g., sexual, overcrowding, nosocomial infection)
● Poor nutritional status, poverty, and homelessness
● Hot, tropical climates
● Seasonal variation: Incidence may be higher in the winter than in the summer (due to overcrowding).
● Immunocompromised patients, including those with HIV/AIDS, are at increased risk of developing severe (crusted/Norwegian) scabies.

GENERAL PREVENTION
Prevent outbreaks by prompt treatment and cleansing of fomites (see “General Measures”).

DIAGNOSIS

HISTORY
● Generalized itching is often severe and worse at night.
Identify potential contact with infected individuals.
Initial/primary infection usually asymptomatic for the first 3 to 4 weeks (until sensitivity occurs)
Subsequent reinfection typically develops symptoms after only 1 to 3 days.

PHYSICAL EXAM
Lesions (inflammatory, erythematous, pruritic papules) most commonly located in the finger webs, flexor surfaces of the wrists, elbows, axillae, buttocks, genitalia, feet, and ankles; often spares the head/neck in adults
Burrows (thin, curvy lines in the upper epidermis that measure 1 to 10 mm in length)—a pathognomonic sign of scabies
Secondary erosions and excoriations from scratching
Pustules (if secondarily infected)
Pruritic nodules in covered areas (buttocks, groin, axillae) resulting from an exaggerated hypersensitivity reaction
Crusted scabies (or Norwegian scabies) is a psoriasiform dermatosis occurring with hyperinfection with thousands/millions of mites (more common in immunosuppressed patients).

Geriatric Considerations
The elderly often itch more severely despite fewer cutaneous lesions and are at risk for extensive infestations, perhaps related to a decline in cell-mediated immunity. There may be back involvement in those who are bedridden.

Pediatric Considerations
Infants and very young children often present with vesicles, papules, and pustules and have more widespread involvement, including the hands, palms, feet, soles, body folds, and head (rare for adults).

DIFFERENTIAL DIAGNOSIS
● Atopic dermatitis
● Contact dermatitis
● Folliculitis/impetigo
● Tinea corporis
● Dermatitis herpetiformis
● Eczema
● Insect bites
● Papular urticaria
● Pediculosis corporis
● Psoriasis (crusted scabies)
● Pyoderma
● Seborrheic dermatitis
● Syphilis

DIAGNOSTIC TESTS & INTERPRETATION
● Based on 2018 IACS (International Alliance Control for Scabies) Criteria for the Diagnosis of Scabies (2)[C]:
  – Confirmed scabies diagnosis: based on microscopic identification of mites, eggs, or fecal
pellets (scybala) OR visualization of mite with dermoscopy
– Clinical scabies diagnosis: detection of burrows, OR typical lesions on male genitalia, OR typical lesions in a typical distribution with two history features of itch and known infectious contact
– Suspected scabies diagnosis: typical lesions in a typical distribution with one history feature of itch or known infectious contact, OR atypical lesions or atypical distribution with two history features of itch and known infectious contact
• A failure to find mites does not rule out scabies.

Initial Tests (lab, imaging)
CBC is rarely needed but may show eosinophilia.

Diagnostic Procedures/Other
• Examination of skin with dermoscopy
  – Look for typical burrows in finger webs, on flexor aspect of the wrists, and on the penis.
  – Look for a dark point at the end of the burrow (the mite, also known as “delta wing sign”).
• Skin scraping
  – Place a drop of mineral oil over a nonexcoriated lesion or burrow.
  – Scrape the lesion with a surgical blade (no. 15).
  – Examine scrapings under a microscope for mites, eggs, egg casings, or feces (3)[C].
  – Scraping under fingernails may be positive.
  – When mite is not found with scraping, biopsy may reveal mite, eggs, or feces.
• Potassium hydroxide (KOH) wet mount NOT recommended because it can dissolve mite pellets
• Burrow ink test
  – If burrows are not obvious, apply gentian violet or India ink to an area of rash. Wash off the ink with alcohol. A burrow should remain stained and become more evident. Then apply mineral oil, scrape, and observe microscopically, as noted previously.

Test Interpretation
Skin biopsy of a nodule (although performed rarely) will reveal portions of the mite in the corneal layer.

TREATMENT

GENERAL MEASURES
• Treat all intimate contacts (including close household and family members).
• Treat items in contact with skin. Wash all clothing, bed linens, and towels in hot (60°C) water and dry in hot dryer. Personal items that cannot be washed should be sealed in a plastic bag for at least 3 to 5 days.
• Itching and dermatitis can persist for up to 4 weeks and can be treated with oral antihistamines and/or topical/oral corticosteroids. It is important to educate patients this is likely not a sign of treatment failure.

MEDICATION
First Line
• Permethrin 5% cream (Elimite) is generally accepted as first-line therapy (4,5)[A].
After bathing or showering, apply cream from the neck to the soles of the feet, paying particular attention to areas that are most involved and then wash off after 8 to 14 hours. It is recommended to repeat treatment 1 to 2 weeks later. The adult dose is usually 30 g per treatment. Side effects include itching and stinging (minimal absorption).

- **Ivermectin (Stromectol) (4,5)[A]**
  - Not FDA-approved for scabies
  - 200 μg/kg PO as a single dose; repeated in 1 week (because not ovicidal)
  - Take with food to improve bioavailability and enhance penetration into the epidermis.
  - May need higher doses or may need to use in combination with topical scabicide for HIV-positive patients

**Crusted scabies** often require more frequent application of permethrin (q2–3d for 1 to 2 weeks) in combination with repeated doses of PO ivermectin on days 1, 2, 8, 9, and 15. Severe cases may need further dosing of ivermectin on days 22 and 29 (2)[C].

**Pediatric Considerations**

- Permethrin may be used on infants >2 months of age. In children <5 years of age, the cream should be applied to the head and neck as well as to the entire body.
- PO ivermectin should be avoided in children <5 years and in those weighing <15 kg.

**Second Line**

- **Crotamiton (Eurax) 10% cream**
  - Apply from the neck down for 24 hours, rinse off, reapply for an additional 24 to 48 hours, and then thoroughly wash off.
  - Nodular scabies: Apply to nodules for 24 hours, rinse off, reapply for an additional 24 hours, and then thoroughly wash off.

- **Precipitated sulfur 2–10% in petrolatum**
  - Not FDA-approved for scabies
  - Apply to the entire body from the neck down for 24 hours, rinse by bathing and then repeat for 2 more days (3 days total). It is malodorous and messy but is thought to be safer than lindane, especially in infants <6 months of age and safer than permethrin in infants <2 months of age.

- **Lindane (γ-benzene hexachloride, Kwell) 1% lotion**
  - Apply a thin layer to all skin surfaces from the neck down and wash off 6 to 8 hours later.
  - Two applications 1 week apart are recommended but may increase the risk of toxicity.
  - 2 oz is usually adequate for an adult.
  - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
  - Contraindications: uncontrolled seizure disorder, premature infants
  - Precautions: Do not use on excoriated skin, on immunocompromised patients, in conditions that may increase risk of seizures, or with medications that decrease seizure threshold.
  - Possible interactions: concomitant use with medications that lower the seizure threshold
  - Some instances of lindane-resistant scabies have been reported. These cases do respond to permethrin.

**ALERT**

Lindane: FDA black box warning of severe neurologic toxicity; use only when all other agents have failed.
Pediatric Considerations
- The FDA recommends caution when using lindane in patients who weigh <50 kg. It is not recommended for infants and is contraindicated in premature infants.
- Infants <2 months should be treated with crotamiton or sulfur preparation.

Pregnancy Considerations
- Permethrin is pregnancy Category B, and lindane, ivermectin, and crotamiton are Category C.
- Permethrin is considered compatible with lactation, but if permethrin is used while breastfeeding, the infant should be bottlefed until the cream has been thoroughly washed off.

ISSUES FOR REFERRAL
Consider referral to dermatology if unable to confirm diagnosis and/or resistant to repeated treatments.

ADDITIONAL THERAPIES
- Crusted scabies may require use of keratolytics to improve penetration of permethrin.
- Nodular scabies may require intralesional steroids for complete resolution, if they persist for several weeks after treatment.
- Benzyl benzoate lotion (not available in the United States but used widely in developing countries)
  - Not FDA-approved for scabies
  - Dose for adults is 25–28%; dilute to 12.5% for children and 6.25% for infants.
  - After bathing, apply lotion from the neck to soles of feet for 24 hours.
- Topical ivermectin 1% lotion (investigational, moderate level of certainty)
  - Not FDA-approved for scabies
  - Apply to affected sites and wash off 8 hours later (5)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Recheck patient at weekly intervals only if rash or itching persists. Scrape new lesions and retreat if mites or products are found.

PATIENT EDUCATION
- Patients should be instructed on proper application and cautioned not to overuse the medication when applying it to the skin.
- A patient fact sheet is available from the CDC: http://www.cdc.gov/parasites/scabies/

PROGNOSIS
Lesions begin to regress in 1 to 2 days, but eczema and itching may persist for up to 4 weeks after treatment.

COMPLICATIONS
- Poor sleep due to pruritus
- Social stigma
- Secondary bacterial infection (more common in developing countries). Impetigo due to Group
A Streptococci and Staphylococcus aureus may lead to sepsis, poststreptococcal glomerulonephritis, and rheumatic heart disease.

- Eczema
- Pyoderma
- Postscabetic pruritus
- Nodules (nodular scabies) may persist for weeks to months after treatment.

CODES

ICD10
B86 Scabies

CLINICAL PEARLS

- Prior to diagnosis, use of a topical steroid to treat pruritic symptoms may mask symptoms and is termed scabies incognito.
- Environmental control is recommended. All linens, towels, and clothing used in the previous 4 days should be washed in hot water or dry-cleaned. Personal items that cannot be washed or dry-cleaned should be sealed in a plastic bag for 3 to 5 days.
- All intimate contacts should receive treatment.
- Close contacts (those sharing the same bed or who have intimate contact) may not show signs and symptoms immediately but should be treated simultaneously to avoid reinfection.
- Eczema and itching may persist for up to 4 weeks after treatment, causing many patients to falsely believe that they have failed treatment or are being reinfected.
- In patients with actual reinfection, it is possible the patient has not applied the medication properly or, more likely, the index patient has not been identified and treated.
SCARLET FEVER
John C. Huscher, MD

BASICS
DESCRIPTION
- A disease (typically in childhood) characterized by fever, pharyngitis, and rash caused by group A β-hemolytic Streptococcus pyogenes (GAS) that produces erythrogenic toxin
- Incubation period: 1 to 7 days
- Duration of illness: 4 to 10 days
- Rash usually appears on the second day of illness.
- Rash first appears on the upper chest and flexural creases and then spreads rapidly all over the body.
- Rash clears at the end of the 1st week and is followed by several weeks of desquamation.
- System(s) affected: head, eyes, ears, nose, throat, skin/exocrine
- Synonym(s): scarlatina

EPIDEMIOLOGY
Incidence
- In developed countries, 15% of school age children and 4–10% of adults have an episode of GAS pharyngitis each year.
- Scarlet fever is rare in infancy because of maternal antitoxin antibodies.
- Predominant age: 6 to 12 years
- Peak age: 4 to 8 years
- Predominant sex: male = female
- Rare in the United States in persons >12 years because of high rates (>80%) of lifelong protective antibodies to erythrogenic toxins

Prevalence
- 15–30% of cases of pharyngitis in children are due to GAS; 5–15% in adults
- <10% of children with streptococcal pharyngitis develop scarlet fever.

ETIOLOGY AND PATHOPHYSIOLOGY
- Erythrogenic toxin production is necessary to develop scarlet fever.
- Three toxin types: A, B, C
- Toxins damage capillaries (producing rash) and act as superantigens, stimulating cytokine release.
- Antibodies to toxins prevent development of rash but do not protect against underlying infection.
- Primary site of streptococcal infection is usually within the tonsils, but scarlet fever may also occur with infection of skin, surgical wounds, or uterus (puerperal scarlet fever).

RISK FACTORS
- Winter/spring seasonal increase
- More common in school-aged children
- Contact with infected individual(s)
Crowded living conditions (e.g., lower socioeconomic status, barracks, child care, schools)

**GENERAL PREVENTION**
- Spread by contact with airborne respiratory droplets
- Asymptomatic contacts do not require cultures/prophylaxis.
- Symptomatic contacts of a child with documented GAS infection who have recent or current clinical evidence of a GAS infection should undergo appropriate laboratory tests and should be treated if test results are positive.
- Children should not return to school/daycare until they have received 24 hours of antibiotic therapy.

**COMMONLY ASSOCIATED CONDITIONS**
- Pharyngitis
- Impetigo
- Rheumatic fever
- Glomerulonephritis

**DIAGNOSIS**

**HISTORY**
Prodrome: 1 to 2 days
- Sore throat
- Headache
- Myalgias
- Malaise
- Fever (>38°C [100.4°F])
- Vomiting
- Abdominal pain (may mimic acute abdomen)
- Rash—scarlatiniform erythematous punctate eruption
- Cough, conjunctivitis, hoarseness, and rhinorrhea are more commonly associated with viral infections.

**PHYSICAL EXAM**
- Oral exam
  - Beefy red tonsils and pharynx with/without exudate
  - Petechiae on palate
  - White coating on tongue: White strawberry tongue appears on days 1 to 2. This sheds by days 4 to 5, leaving a red strawberry tongue, which is shiny and erythematous with prominent papillae.
- Exanthem (appears within 1 to 5 days)
  - Scarlet macules with generalized erythema; blanches when pressed
  - Orange-red punctate skin eruption with sandpaperlike texture, “sunburn with goose pimples”
  - Coarse “sand paper” rash, initially appearing on chest and axillae, and then spreading to abdomen and extremities; prominent in skin folds, flexural surfaces (e.g., axillae, groin, buttocks), with sparing of palms and soles
  - Flushed face with circumoral pallor, red lips
– Pastia lines: transverse red streaks in skin folds of abdomen, antecubital space, and axillae
– Desquamation begins on face after 7 to 10 days and proceeds over trunk to hands and feet; may persist for 6 weeks
– In severe cases, small vesicular lesions (miliary sudamina) may appear on abdomen, hands, and feet.

**DIFFERENTIAL DIAGNOSIS**
- Viral exanthem: measles; rubella; roseola
- Infectious mononucleosis
- Mycoplasma pneumonia
- Secondary syphilis
- Toxic shock syndrome
- Staphylococcal scalded-skin syndrome
- Kawasaki disease
- Drug hypersensitivity
- Severe sunburn

**DIAGNOSTIC TESTS & INTERPRETATION**
- The signs and symptoms of streptococcal and nonstreptococcal pharyngitis overlap too broadly for diagnosis to be made with precision on clinical grounds alone. Even patients with all clinical features are confirmed to have streptococcal pharyngitis only about 35–50% of the time, particularly in children.
- Use results from rapid antigen detection testing (RADT) or polymerase chain reaction (PCR) based rapid testing.
- Modified Centor Score clinical decision rule
  - Absence of cough 1 point
  - Swollen, tender anterior cervical nodes 1 point
  - Temperature 100.4°F (38°C) 1 point
  - Tonsillar exudate or swelling 1 point
  - Age:
    - 3 to 14 years 1 point
    - 15 to 44 years 0 point
    - 45 years or older – 1 point
- Cumulative score:
  - 0: Risk of GAS pharyngitis 1–2.5%—no further testing or antibiotics indicated
  - 1: Risk of GAS pharyngitis 5–10%—no further testing or antibiotics indicated—option to perform throat culture or RADT—treat if positive.
  - 2: Risk of GAS pharyngitis 11–17%—perform throat culture or RADT—treat if positive.
  - 3: Risk of GAS pharyngitis 28–35%—perform throat culture or RADT—treat if positive.
  - 4+: Risk of GAS pharyngitis 51–53%—consider empiric treatment with antibiotics.
- Testing for GAS pharyngitis is not recommended for patients with symptoms suggesting a viral etiology (e.g., cough, rhinorrhea, hoarseness, oral ulcers).

**Initial Tests (lab, imaging)**
- RADT: diagnostic if positive; sensitivity approaches that of culture, 95% specific. In children, negative RADT should be confirmed by throat culture (not necessary in adults). Positive RADT does not require confirmatory culture ([1][C]).
PCR: diagnostic if positive, 100% sensitive, 94.1% specific, 84.1% positive predictive value, 100% negative predictive value. Positive PCR does not require confirmatory culture.

- Throat culture is the gold standard to confirm streptococcal infection (99% specific, 90–97% sensitive; 5–10% of healthy individuals are carriers) (1).
- Serologic tests (antistreptolysin O titer and streptozyme tests, antihyaluronidase): Confirm recent GAS infection; not helpful or recommended for diagnosis of acute disease
- Gram stain: gram-positive cocci in chains
- CBC may show elevated WBC count (12,000 to 16,000/mm$^3$); eosinophilia later (second week)
- Follow-up (posttreatment) throat cultures or RADT/PCR not routinely recommended
- Diagnostic testing and empiric treatment of asymptomatic household contacts of patients with acute streptococcal pharyngitis is not routinely recommended (2)[B].

Follow-Up Tests & Special Considerations
- Recent antibiotic therapy may impact culture results.
- Within 5 days of symptoms, antibiotics can delay/abolish antistreptolysin O response.

Test Interpretation
Skin lesions reveal characteristic inflammatory reaction, specifically hyperemia, edema, and polymorphonuclear cell infiltration.

TREATMENT
GENERAL MEASURES
Supportive care; analgesic/antipyretic such as acetaminophen or NSAID for moderate to severe symptoms or to control fever. Symptomatic treatment can include medicated throat lozenges and topical anesthetics.

MEDICATION
First Line
The primary reason for treating GAS is to decrease the risk of acute rheumatic fever. Early treatment decreases duration of symptoms by 1 to 2 days and decreases the period of contagiousness. Penicillin is the drug of choice for GAS pharyngitis given its proven efficacy, safety, narrow spectrum, and low cost.

- Penicillin (PO; penicillin V and others) for 10 days
  - 250 mg PO BID or TID for <27 kg (60 lb); 250 mg QID or 500 mg BID for >27 kg (60 lb) adolescents and adults (1)[A],(3)[A],(4)[A]
  - If compliance is questionable, use penicillin G benzathine: single IM dose 600,000 U for <27 kg (60 lb); 1.2 mU for those >27 kg
- Amoxicillin (PO) 50 mg/kg (max dose 1,000 mg) once daily or 25 mg/kg (max dose 500 mg) twice daily for 10 days (use only for definitive GAS because it can induce rash with some viral infections)
  - Contraindications: penicillin allergy
- Precautions: Avoid in patients with penicillin allergy (anaphylaxis).

Second Line
For patients allergic to penicillin

- **Type IV hypersensitivity to penicillin:**
  - Oral cephalosporins: Many are effective, but 1st-generation cephalosporins are less expensive:
    - Cephalexin: 20 mg/kg dose twice daily for 10 days; max 500 mg every 12 hours [A]
    - Cefadroxil: 30 mg/kg once daily; max 1,000 mg for 10 days [1]
- **Type I hypersensitivity to penicillin:**
  - Azithromycin (Zithromax, Z pack): 12 mg/kg/day (max 500 mg) for 5 days [3][A]
  - Clarithromycin (Biaxin): children >6 months: 7.5 mg/kg BID for 10 days; adults: 250 mg BID for 10 days
  - Clindamycin: 7 mg/kg (max 300 mg/dose) TID for 10 days [3][B]

**T**etrazyclines and sulfonamides should not be used.

**ALERT**
Avoid aspirin in children due to risk of Reye syndrome.

**ISSUES FOR REFERRAL**
Peritonsillar abscess; shock symptoms: hypotension, disseminated intravascular coagulation (DIC), cardiac, liver, renal dysfunction

**SURGERY/OTHER PROCEDURES**
- Tonsillectomy is recommended with recurrent bouts of pharyngitis (≥6 positive strep cultures in 1 year).
- Although children still may get streptococcal pharyngitis (“strep throat”) after a tonsillectomy, the procedure reduces the frequency and severity of infections.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow-up throat culture not needed unless symptomatic

**Patient Monitoring**
GAS is uniformly susceptible to penicillin. Treatment failures are typically due to:
- Poor adherence to recommended antibiotic therapy
- β-Lactamase oral flora hydrolyzing penicillin
- GAS carrier state and concurrent viral rash (requires no treatment)
- Repeat exposure to carriers in family: Streptococci persist on unrinsed toothbrushes and orthodontic appliances for up to 15 days.
- Retreat recurrent GAS pharyngitis with the same agent, an alternative oral agent, or IM penicillin G.

**DIET**
No special diet

**PATIENT EDUCATION**
- Delay in treatment awaiting culture results does not increase the risk of rheumatic fever.
- Complete the entire course of antibiotics.
Children should not return to school/daycare until they have received >24 hours of antibiotic therapy.

- Can spread person to person. Personal hygiene is important (wash hands, don’t share utensils).

**PROGNOSIS**

- Treatment shortens symptoms by 12 to 24 hours.
- Recurrent attacks are possible (different erythrogenic toxins).

**COMPLICATIONS**

- Suppurative
  - Sinusitis
  - Otitis media/mastoiditis
  - Cervical adenitis
  - Peritonsillar abscess/retropharyngeal abscess
  - Pneumonia
  - Bacteremia with metastatic infectious foci: meningitis, brain abscess, osteomyelitis, septic arthritis, endocarditis, intracranial venous sinus thrombosis, necrotizing fasciitis
- Nonsuppurative
  - Rheumatic fever: Therapy prevents rheumatic fever when started as long as 10 days after onset of acute GAS infection.
  - Glomerulonephritis: due to nephritogenic strain of Streptococcus; prevention even after adequate treatment of GAS is less certain.
  - Streptococcal toxic shock syndrome: fever; hypotension; DIC; and cardiac, liver, and/or kidney dysfunction due to other toxin-mediated sequelae
  - Poststreptococcal reactive arthritis—a reactive arthritis following a pharyngeal streptococcal infection with a symptom free interval and subsequent aseptic inflammation of one or more joints typically without cardiac involvement
  - Cellulitis
  - Weeks to months later, may develop transverse grooves in nail plates and hair loss (telogen effluvium)
  - Pediatric autoimmune neuropsychiatric disorder associated with GAS (PANDAS). A subset of children has been recognized whose symptoms of obsessive-compulsive disorder (OCD) or tic disorders are exacerbated by GAS infection.

**REFERENCES**

ADDITIONAL READING

SEE ALSO

- Pharyngitis
- Algorithm: Pharyngitis

CODES

ICD10
- A38.9 Scarlet fever, uncomplicated
- J02.0 Streptococcal pharyngitis
- A38.0 Scarlet fever with otitis media

CLINICAL PEARLS

- Consider scarlet fever in the differential diagnosis of children with fever and an exanthematous rash.
- Key clinical findings include strawberry tongue, circumoral pallor, and a coarse sandpaper rash.
- Desquamation (7 to 10 days after symptom onset) may last for several weeks following scarlet fever.
- Diagnose GAS pharyngitis using a validated clinical decision rule (Modified Centor Score) and selective use of RADT.
- Penicillin remains the drug of choice.
SCHIZOPHRENIA
Jeffrey Stovall, MD ● Stephanie M. Fall, MD

BASICS
Schizophrenia is a severe and persistent psychiatric condition characterized by delusions, hallucinations, disorganization, cognitive dysfunction, and impairment in reality testing.

DESCRIPTION
- Major psychiatric disorder with a variable course, typically involving prodromal, active, and residual psychotic symptoms with disturbances in thought, speech, affect, behavior, and perception
- DSM-5 eliminated subcategories of schizophrenia (paranoid, disorganized, catatonic, etc.)
- System(s) affected: central nervous system (CNS)

EPIDEMIOLOGY
Incidence
- 7.7 to 43/100,000
- Predominant sex: male-to-female ratio = 1.4:1.0
- Age of onset: typically <30 years, earlier in males (late teens to mid-20s) than females (early 20s to early 30s), with a smaller peak that occurs in women >45 years; more subtle changes in cognition and functioning can precede the diagnosis (prodromal period) by several years

Prevalence
- Lifetime (1%): highest prevalence in lower socioeconomic classes and urban settings (2-fold higher risk)
- 1.1% of the population >18 years old; similar rates in all countries

ETIOLOGY AND PATHOPHYSIOLOGY
- Stems from a complex interaction between genetic and environmental factors; higher incidence if prenatal infection or hypoxia, winter births, first-generation immigrants, advanced paternal age, drug use, and genetic (velocardiofacial) syndromes
- Overstimulation of mesolimbic dopamine D_2 receptors, deficient prefrontal dopamine, and aberrant prefrontal glutamate (NMDA) activity results in perceptual disturbances, disordered thought process, and cognitive impairments

Genetics
If first-degree biologic relative has schizophrenia, risk is 8–10% (a 10-fold increase).

GENERAL PREVENTION
- Currently, no known preventive measures decrease the incidence of schizophrenia. Early intervention programs, however, aim to identify people at high risk and limit the duration of untreated psychosis.
- It is important to educate all patients on the risks around marijuana use, especially those in a potential prodromal period or those with a family history of psychosis.
- Interventions to improve long-term outcome and associated comorbid conditions are employed during management.
COMMONLY ASSOCIATED CONDITIONS
- Nicotine dependence (>50%) and substance use disorders are common and lead to significant long-term medical and social complications.
- Metabolic syndrome, diabetes mellitus, obesity, and certain infectious diseases, including HIV, hepatitis B, and hepatitis C all occur in higher-than-expected rates in individuals with schizophrenia.

DIAGNOSIS
Focus on identifying an insidious social and functional decline over a ≥ 6-month period (differentiates schizophrenia from brief psychotic and schizophreniform disorders). At least 2 of the following core symptoms must be present for ≥ 1 month:
- Delusions (fixed, false beliefs)
- Hallucinations (auditory > visual disturbances)
- Disorganized thought (derailed or incoherent speech)
- Grossly disorganized/catatonic behavior (hyper- or hypoactive movements that are often repetitive)
- Negative symptoms (diminished emotional expression, poverty of speech and thought, amotivation, lack of social interest)

PHYSICAL EXAM
No physical findings characterize the illness; however, chronic treatment with neuroleptic agents may result in extrapyramidal symptoms, including dystonia (sustained muscle contractions), akathisia (restlessness), parkinsonism (tremor, shuffling gait), or tardive dyskinesia (repetitive, involuntary movements).

DIFFERENTIAL DIAGNOSIS
- Brief psychotic disorder (symptom duration <1 month)
- Schizophreniform disorder (symptom duration 1 to 6 months)
- Psychotic disorder due to another medical condition
  - Disorientation and altered level of arousal raise concern for delirium.
  - Possible medical illnesses include TBI, infection, tumor, epilepsy, Huntington’s disease, anti-NMDA limbic encephalitis, and many others
- Substance-induced psychosis: secondary to substance use/abuse, such as cocaine, hallucinogens (amphetamines, LSD, phencyclidine), cannabis (including synthetic), bath salts, alcohol, or prescribed medications including steroids, anticholinergics, and opiates
  - About 25% of patients with substance-induced psychosis will transition to schizophrenia.
  - Highest transition rates are associated with cannabis use.
- Personality disorders: paranoid, schizotypal, schizoid, borderline personality disorders
- Mood disorders: bipolar disorder, major depressive disorders with psychotic features or catatonia
- Other thought disorders: delusional disorder, schizoaffective disorder
- Posttraumatic stress disorder
- Autism spectrum disorder or neurodevelopmental disorders
- Cultural belief system

DIAGNOSTIC TESTS & INTERPRETATION
No tests are available to indicate schizophrenia.

Imaging (MRI), EEG, LP, and laboratory tests may be needed to rule out other causes and may be used as clinical presentation warrants.

**Initial Tests (lab, imaging)**

- The following labs are often used to rule out a medical etiology of psychotic symptoms:
  - Thyroid-stimulating hormone (TSH), complete blood count (CBC), blood chemistries
  - Vitamin levels (thiamine, vitamin D, methylmalonic acid/vitamin B$_{12}$, folate)
  - Drug/alcohol screen of blood and urine, urinalysis
  - Syphilis screen, HIV
  - Heavy-metal exposure: lead, mercury
  - Ceruloplasmin, urine porphobilinogen as indicated
  - Erythrocyte sedimentation rate, antinuclear antibody
  - Hepatitis C, hepatitis B

- The following labs are used to assess for comorbidities and baseline values prior to antipsychotic initiation:
  - Electrocardiogram (ECG) for baseline QTc
  - CBC, blood chemistries, TSH
  - Hemoglobin A1C
  - Blood glucose level, preferably fasting
  - Lipid panel, preferably fasting
  - Pregnancy test, if indicated

**Follow-Up Tests & Special Considerations**

Clinical and laboratory tests for routine monitoring, at least yearly, if using antipsychotic medications:

- Weight, waist circumference, and blood pressure
- Fasting blood glucose level, hemoglobin A1C, fasting lipid panel
- CBC
- Pregnancy test and prolactin level, if indicated
- ECG, monitoring for QTc prolongation
- Clinical assessment of extrapyramidal symptoms using a standardized test such as the Abnormal Involuntary Movement Scale (AIMS)

**Diagnostic Procedures/Other**

Neuropsychological testing: not a routine part of assessment but can help assess cognitive level to predict functioning and need for assistance

**Test Interpretation**

No diagnostic pathologic findings; however, ventriculomegaly is frequently seen on MRI with whole brain gray matter loss and white matter loss in medial temporal lobe structures preferentially.

---

**TREATMENT**

**MEDICATION**
First Line

- Two classes of antipsychotic medications: typical and atypical. First-line treatment is with an atypical antipsychotic given lower potential for extrapyramidal side effects.
  - Atypical (2nd generation)
    - Risperidone, olanzapine, ziprasidone, aripiprazole, quetiapine, paliperidone, iloperidone, asenapine, lurasidone, clozapine, brexpiprazole, cariprazine, pimavanserin (Parkinson disease–related psychosis)
  - Typical (1st generation)
    - Haloperidol, chlorpromazine, fluphenazine, trifluoperazine, perphenazine, thioridazine, thiothixene, loxapine

- Medication choice is based on clinical and subjective response and side-effect profile (1)
  - Sensitivity to extrapyramidal adverse effects: atypicals
  - For least risk of tardive dyskinesia: Quetiapine, clozapine
  - For least risk of metabolic syndrome: Aripiprazole, ziprasidone, lurasidone, perphenazine, brexpiprazole
  - For least risk of QTc prolongation: Aripiprazole
    - Avoid use of thioridazine and ziprazidone in patients with a prolonged QT interval.
  - For poor compliance/high risk of relapse: Injectable form of long-acting antipsychotic may be used.
    - Haloperidol, fluphenazine, risperidone, olanzapine, aripiprazole, and paliperidone

- Usual maintenance daily range (initiation is commonly at a lower dose)
  - Chlorpromazine: 200 to 800 mg/day divided BID/TID/QID
  - Aripiprazole: 10 to 30 mg/day
  - Asenapine: 5 to 10 mg BID (sublingual), once daily patch (FDA approved in October 2019)
  - Fluphenazine: 5 to 20 mg/day
  - Haloperidol: 5 to 20 mg/day
  - Lurasidone: 40 to 80 mg/day (with meal)
  - Olanzapine: 10 to 30 mg/day
  - Paliperidone: 3 to 12 mg/day
  - Perphenazine: 24 mg/day divided BID/TID
  - Quetiapine: 200 to 400 mg BID
  - Risperidone: 2 to 8 mg/day
  - Ziprasidone: 20 to 80 mg BID (with meal)
  - Cariprazine: 1.5 to 6.0 mg/day
  - Brexpiprazole: 2 to 4 mg/day
  - Pimavanserin (for Parkinson disease-related psychosis): 34 mg/day
  - Clozapine: 200 mg BID
    - Typical dosage range is 300 to 600 mg/day split into BID dosing
    - The gold standard treatment for refractory schizophrenia
    - Effective in treatment of suicidal patients
    - Serious risk of agranulocytosis mandates registration with National Clozapine Registry and weekly to monthly monitoring of CBC with differential
    - Significant risk of seizure at higher doses
    - SE can include myocarditis, DVT, sialorrhea, tachycardia, and weight gain

**ALERT**
All antipsychotics are associated with weight gain and carry the risk of metabolic SE and tardive...
dyskinesia.

- Managing adverse effects of antipsychotics
  - Dystonic reaction (especially of head and neck): diphenhydramine 25 to 50 mg IM or benztpoine 1 to 2 mg IM
  - Akathisia (restlessness): propranolol 20 to 30 mg BID or lorazepam 0.5 to 1.0 mg BID
  - Parkinsonism: trihexyphenidyl 2 mg BID (up to 15 mg daily) or benztpoine 0.5 BID (1 to 4 mg/day); amantadine 100 mg daily (up to 300 mg daily)
  - Tardive dyskinesia: valbenazine (80 mg daily), tetrabenazine (25 to 50 mg TID), or deutetrabenazine (6 to 24 mg BID)
  - Neuroleptic malignant syndrome: hyperthermia, autonomic dysfunction, and extrapyramidal symptoms; requires hospitalization and supportive management (IVF and cessation of offending neuroleptic)
  - Metabolic syndrome: metformin

- Geriatric considerations: All antipsychotics carry a black box warning for increased mortality risk in elderly patients with dementia.

- Adjunctive treatments
  - Benzodiazepines
    - May be effective adjunct to antipsychotics during acute phase of illness, especially when anxiety is prominent
    - First-line for the treatment of catatonia
    - Withdrawal reactions with psychosis or seizures; risk for dependence and cognitive impairment
    - Best when used only in the short-term; high cumulative exposure to benzodiazepines is associated with a significantly increased risk of death in patients with schizophrenia
  - Mood stabilizers
    - Valproic acid may be effective adjunct for those with agitated/violent behavior (1).
    - Lithium may be effective adjunct for patients with prominent affective symptoms or suicidal ideation (1).
  - Antidepressants:
    - Useful if comorbid depression and/or anxiety are present
    - Associated with a lower risk of psychiatric hospitalization when added to antipsychotic monotherapy compared to adding a second antipsychotic (2)[B]

ISSUES FOR REFERRAL
- Consider referral in cases of suicidality, coexistence of a substance use disorder, difficulty in engagement, or poor self-care.
- Patients with schizophrenia should receive multidisciplinary care from both a primary care physician and a psychiatrist.
- Family members often benefit from referral to family advocacy organizations such as NAMI.

ADDITIONAL THERAPIES
- Psychoeducation and psychotherapy for patient and family: These include specific treatments to reduce the impact of psychotic symptoms, enhance social functioning, and reduce risk of symptom exacerbation. Cognitive-behavioral therapy has been shown to be effective for specific symptoms of schizophrenia (1).
- Cognitive remediation is a new approach for cognitive retraining and psychosocial recovery.
- Vocational support programs have shown success in returning individuals to work.
Negative symptoms typically respond better to these non-pharmacologic interventions than they do to medications.

**SURGERY/OTHER PROCEDURES**
- Electroconvulsive therapy (ECT) should be considered early for patients presenting with catatonic features
- ECT should also be considered when severe depression or suicidality are present.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Initial stabilization focuses on maintaining a safe environment and reducing acute psychotic symptoms and agitation through the initiation of pharmacologic treatment.
- The decision to admit is usually based on the patient’s risk of self-harm or harm to others and the inability to care for self.
- Monitor for safety concerns and establish a safe and supportive environment.
- Discharge criteria is based on the patient’s ability to remain safe in the community. It reflects a combination of suicide risk, level of psychotic symptoms, support systems, and the availability of appropriate outpatient services.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Long-term symptom management and rehabilitation depend on engagement in ongoing pharmacologic and psychosocial treatment.
- Monitoring is based on evaluation of symptoms (including safety and psychotic symptoms), looking for the emergence of comorbidities, medication side effects, and prevention of complications.

**DIET**
- Atypical antipsychotics confer a higher risk of metabolic side effects such as diabetes, hypercholesterolemia, and weight gain.
- Although there are no specific dietary requirements, attention should be paid to the high risk of development of obesity and metabolic syndrome in individuals with schizophrenia.

**PATIENT EDUCATION**
- Helping a Family Member with Schizophrenia: www.aafp.org/afp/20070615/1830ph.html
- National Alliance on Mental Illness: www.NAMI.org

**PROGNOSIS**
- Typical course is one of remissions and exacerbations. Although uncommon, there are known cases of complete remission and of refractory illness.
- Negative symptoms are often most difficult to treat; antipsychotics are better at treating positive symptoms.
- About 20% attempt and 5–6% die of suicide.
- Decreased life span related to comorbidities
COMPLICATIONS

- Side effects from antipsychotics, including tardive dyskinesia, orthostatic hypotension, QTc prolongation, and metabolic syndrome
- Self-inflicted trauma and suicide
- Combative behavior toward others (Only 5% of crimes are caused by mental illness including psychosis.)
- Comorbid substance use disorders

REFERENCES

Algorithm: Delirium

CODES

ICD10

- F20.9 Schizophrenia, unspecified
- F20.0 Paranoid schizophrenia
- F20.1 Disorganized schizophrenia

CLINICAL PEARLS

- Schizophrenia is a severe and persistent mental illness that impacts cognition and functioning and requires a multidisciplinary team approach to assist with coping, treatment, and to promote recovery.
- Schizophrenia is characterized by positive symptoms, including hallucinations and delusions, and negative symptoms, including flattened affect, anhedonia, amotivation, and social withdrawal.
- Substance use disorders are the most common psychiatric comorbidities and should be monitored and treated appropriately.
BASICS

DESCRIPTION
- Scleritis is a painful, inflammatory process of the sclera, part of the eye’s outer coat.
  - Categorized into anterior or posterior and diffuse, nodular, or necrotizing
  - Commonly associated with systemic disorders
  - Potentially vision threatening
- In contrast, episcleritis is a self-limited inflammation of the superficial episclera with only mild discomfort.
- System(s) affected: ocular

EPIDEMIOLOGY
- Mean age is 54 years (range 12 to 96).
- Predominant sex: female > male (1.6:1)

Incidence
Estimated to be 6 cases per 100,000 people in the general population

Prevalence
- Anterior scleritis, about 94% of cases (1)
  - Diffuse anterior scleritis, about 75% (most common)
- Remaining 6% have posterior scleritis.

ETIOLOGY AND PATHOPHYSIOLOGY
- Frequently associated with a systemic illness (1)[B]
  - Most commonly associated with rheumatoid arthritis
  - In about 38% of cases, scleritis is the presenting manifestation of an underlying systemic disorder.
  - Necrotizing scleritis has the highest association with systemic disease.
- Other etiologies
  - Proposed pathogenesis is dependent on type of scleritis. In necrotizing scleritis, the predominant mechanism is likely due to the activity of matrix metalloproteinases.
  - Drug-induced scleritis has been reported in patients on bisphosphonate therapy.
  - Surgically induced necrotizing scleritis is exceedingly rare and occurs after multiple surgeries.
  - Infectious scleritis occurs most commonly after surgical trauma, and Pseudomonas aeruginosa in poorly controlled diabetic patients is the most common causative organism (2)[B].

RISK FACTORS
Individuals with autoimmune disorders are most at risk.

COMMONLY ASSOCIATED CONDITIONS
- Rheumatoid arthritis (most common)
• Sjögren syndrome
• Granulomatosis with polyangiitis
• HLA-B27–associated ankylosing spondylitis
• Systemic lupus erythematosus
• Reactive arthritis
• Behçet disease
• Juvenile idiopathic arthritis
• Cogan disease
• Relapsing polychondritis
• Polyarteritis nodosa
• Sarcoidosis
• Inflammatory bowel disease
• Herpes zoster
• Herpes simplex
• HIV
• Syphilis
• Lyme disease
• Tuberculosis
• IgG4-related disease

**DIAGNOSIS**

**HISTORY**

• Redness and inflammation of the sclera
  – Can be bilateral in about 40% of cases (1)
• Photophobia and tearing
• Pain ranging from mild discomfort to extreme localized tenderness
  – May be described as constant, deep, boring, or pulsating
  – Pain may be referred to the eyebrow, temple, or jaw.
  – Pain may awaken patient from sleep in early hours of morning.
  – Severe pain is most commonly associated with necrotizing scleritis (1)[B].

**PHYSICAL EXAM**

• Examine sclera in all directions of gaze by gross inspection.
  – A bluish hue may suggest thinning of sclera.
  – Inspect for degree of injection and extent of thinning.
• Check visual acuity.
  – Decrease in visual acuity of two or more Snellen lines occurs in about 16% of patients (1)[B].
• Slit-lamp exam using red-free light
  – Episcleritis: conjunctival and superficial vascular plexuses displaced anteriorly; blanches with phenylephrine
  – Scleritis: Deep episcleral plexus is the maximum site of vascular congestion, displaced anteriorly d/t edema of underlying sclera; characteristic blue or violet color, absent in patients with episcleritis
• Dilated fundus exam to rule out posterior involvement
A complete physical exam, particularly of the skin, joints, heart, and lungs, should be done to evaluate for associated conditions.

DIFFERENTIAL DIAGNOSIS
- Conjunctivitis
- Episcleritis
- Iritis (anterior uveitis)
- Posterior uveitis
- Blepharitis
- Ocular rosacea

DIAGNOSTIC TESTS & INTERPRETATION
- Consider further tests if warranted by history and physical.
- Routine tests to exclude systemic disease
  - CBC, serum chemistry, urinalysis, ESR, and/or C-reactive protein, blood, and urine cultures
- Specific tests for underlying systemic illness
  - Rheumatoid factor, anticyclic citrullinated peptide antibodies, ACE level, HLA-B27, antineutrophil cytoplasmic antibodies, PPD or QuantiFERON-TB level, fluorescent treponemal antibody absorption (FTA-ABS), rapid plasma regain (RPR), Lyme titer, and antinuclear antibody may aid in the diagnosis.
- Further imaging studies, such as a chest x-ray, sacroiliac joint films, and colonoscopy, may be useful if a specific systemic illness is suspected.
- B-scan ultrasound to detect posterior scleritis. Look at thickness of sclera and for T-sign, fluid in Tenon space at interface between the optic nerve and sclera.
- MRI/CT scan may provide additional diagnostic benefit and detect orbital disease (3)[C].
- Different subtypes of scleritis are associated with varying presentations and distinct findings:
  - Diffuse anterior scleritis: widespread inflammation
  - Nodular anterior scleritis: immovable, inflamed nodule
  - Necrotizing anterior scleritis: “with inflammation”: Sclera becomes transparent.
    Scleromalacia perforans without inflammation: painless and often associated with rheumatoid arthritis
  - Posterior scleritis: associated with retinal and choroidal complications; adjacent swelling of orbital tissues may occur.

Diagnostic Procedures/Other
Biopsy is not routinely required unless diagnosis remains uncertain after above investigations.
Culture if suspect infectious etiology.

TREATMENT

GENERAL MEASURES
If scleral thinning, glasses/eye shield should be worn to prevent perforation; should be managed by an appropriate eye care professional

MEDICATION
- First-line therapies for noninfectious scleritis (4)[C]
  - Oral NSAID therapy, choice based on availability; example is ibuprofen 600 to 800 mg PO
TID–QID or indomethacin 50 mg PO TID provided no contraindications exists; about 37% successful (5)[B]

- Systemic steroids (initial if necrotizing scleritis and preferentially IV if vision threatening, otherwise use if failure of NSAIDs), prednisone 40 to 60 mg PO QD or 1 mg/kg/day, taper over 4 to 6 weeks. Use caution if suspect infectious etiology.
- Antimetabolites including methotrexate, azathioprine, mycophenolate mofetil, cyclophosphamide, and cyclosporine may be used as steroid-sparing agents. They are generally recommended if steroids cannot be tapered below 10 mg PO QD (5)[C].

- Second-line therapies (5)[C],(6)[A],(7)[C]
  - Immunomodulatory agents, infliximab, rituximab, and adalimumab can be used if patient has failed or is not a candidate for antimetabolites or calcineurin inhibitors. These agents are preferred over etanercept due to higher treatment success.

- Adjunct therapy considerations
  - Topical steroids: prednisolone acetate 1% or difluprednate 0.05% under ophthalmologist care
  - Subconjunctival triamcinolone acetonide injection only for nonnecrotizing, 40 mg/mL, 97% improvement after one injection; increased risk of ocular hypertension (HTN), cataract, and globe perforation

- Necrotizing anterior scleritis and posterior scleritis
  - May require immunosuppressive therapy in addition to systemic steroids
  - Treat aggressively due to possible complications if left untreated; may need patch grafting to maintain globe integrity

- Infectious
  - Antibiotic therapy resolves about 18% of cases, whereas the remaining often requires surgical intervention such as débridement (2)[B].

**ISSUES FOR REFERRAL**
- All patients with scleritis should be managed by an ophthalmologist familiar with this condition.
- Rheumatology referral for coexistent systemic disease is helpful for long-term success.

**ADDITIONAL THERAPIES**
Immunosuppressants used for autoimmune and collagen vascular disorders may be of help in active scleritis.

**SURGERY/OTHER PROCEDURES**
- In rare cases, scleral biopsy may be indicated to confirm infection or other etiology.
- Ocular perforation requires scleral grafting.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Avoid contact lenses—wear only if there is corneal involvement, which is rare.

**Patient Monitoring**
- Patient in the active stage of inflammation should be followed very closely by an ophthalmologist to assess the effectiveness of therapy.
Medication use mandates close surveillance for adverse effects.

**DIET**
No special diet

**PATIENT EDUCATION**
Scleritis at The Ocular Immunology and Uveitis Foundation:
http://www.uveitis.org/patient_articles/scleritis/

**PROGNOSIS**
Scleritis is indolent, chronic, and often progressive.
- Diffuse anterior scleritis (best prognosis)
- Necrotizing anterior scleritis (worst prognosis)
- Recurrent bouts of inflammation may occur.
- Scleromalacia perforans has the highest risk of perforation of the globe.

**COMPLICATIONS**
- Decrease in vision, anterior uveitis, ocular HTN, and peripheral keratitis
- Cataract and glaucoma can result from disease or treatment with steroids.
- Ocular perforation can occur in severe stages.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- H15.009 Unspecified scleritis, unspecified eye
- H15.019 Anterior scleritis, unspecified eye
- H15.039 Posterior scleritis, unspecified eye

**CLINICAL PEARLS**

- Episcleritis is a self-limited inflammation of the eye with mild discomfort.
- Scleritis is a painful, severe, and potentially vision-threatening condition.
- While both conditions can be associated with underlying inflammatory diseases, 35% of scleritis cases are associated with a systemic disease such as rheumatoid arthritis. Necrotizing scleritis has the highest association.
**SCLERODERMA**
Ann M. Lynch, PharmD, RPh, AE-C • Deborah M. DeMarco, MD, FACP

### BASICS

**DESCRIPTION**
- Scleroderma (systemic sclerosis [SSc]) is a chronic disease of unknown cause characterized by diffuse fibrosis of skin and visceral organs and vascular abnormalities.
- Most manifestations have vascular features (e.g., Raynaud phenomenon), but frank vasculitis is rarely seen.
- Can range from a mild disease, affecting the skin, to a systemic disease that can cause death in a few months.
- The disease is categorized into two major clinical variants (1).
  - Diffuse: distal and proximal extremity and truncal skin thickening
  - Limited
    - Restricted to the fingers, hands, and face
    - CREST syndrome (calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, telangiectasia)
- System(s) affected: include, but not limited to skin, renal, cardiovascular, pulmonary, musculoskeletal, gastrointestinal (GI)

**Geriatric Considerations**
Uncommon >75 years of age

**Pediatric Considerations**
Rare in this age group

**Pregnancy Considerations**
- Safe and healthy pregnancies are common and possible despite higher frequency of premature births.
- High-risk management must be standard care to avoid complications, specifically renal crisis.
- Diffuse scleroderma causes greater risk for developing serious cardiopulmonary and renal problems. Pregnancy should be delayed until disease stabilizes.

### EPIDEMIOLOGY

**Incidence**
- In the United States: 1 to 2/100,000 per year
- Predominant age
  - Young adult (16 to 40 years); middle-aged (40 to 75 years); peak onset 30 to 50 years
  - Symptoms usually appear in the 3rd to 5th decades.
- Predominant sex: female > male (4:1)

**Prevalence**
- In the United States: 1 to 25/100,000
ETIOLOGY AND PATHOPHYSIOLOGY
Pathophysiology involves both a vascular component and a fibrotic component. Both occur simultaneously. The inciting event is unknown, but there is an increase in certain cytokines after endothelial cell activation that are profibrotic (TGF-β and PDGF).
- Unknown
- Possible alterations in immune response
- Possibly some association with exposure to quartz mining, quarrying, vinyl chloride, hydrocarbons, toxin exposure
- Treatment with bleomycin has caused a scleroderma-like syndrome, as has exposure to rapeseed oil.

Genetics
Familial clustering is rare but has been seen.

RISK FACTORS
Unknown

DIAGNOSIS

HISTORY
- Raynaud phenomenon is generally the presenting complaint (differentiated from Raynaud disease, generally affecting younger individuals and without digital ulcers).
- Skin thickening, “puffy hands,” pruritus, and gastroesophageal reflux disease (GERD) are often noted early in the disease process.

PHYSICAL EXAM
- Skin
  - Digital ulcerations
  - Digital pitting
  - Tightness, swelling, thickening of digits
  - Hyperpigmentation/hypopigmentation
  - Narrowed oral aperture
  - SC calcinosis
- Peripheral vascular system
  - Telangiectasia
- Joints, tendons, and bones
  - Flexion contractures
  - Friction rub on tendon movement
  - Hand swelling
  - Joint stiffness
  - Polyarthralgia
  - Sclerodactyly
- Muscle
  - Proximal muscle weakness
- GI tract
  - Dysphagia
– Esophageal reflux due to dysmotility (most common systemic sign in diffuse disease)
– Malabsorptive diarrhea
– Nausea and vomiting
– Weight loss
– Xerostomia

• Kidney
  – Hypertension
  – May develop scleroderma renal crisis: acute renal failure (ARF)

• Pulmonary
  – Dry crackles at lung bases
  – Dyspnea

• Nervous system
  – Peripheral neuropathy
  – Trigeminal neuropathy

• Cardiac (progressive disease)
  – Conduction abnormalities
  – Cardiomyopathy
  – Pericarditis
  – Secondary cor pulmonale

DIFFERENTIAL DIAGNOSIS
• Mixed connective tissue disease/overlap syndromes
• Scleredema
• Nephrogenic systemic fibrosis
• Toxic oil syndrome (Madrid, 1981, affecting 20,000 people)
• Eosinophilia–myalgia syndrome
• Diffuse fasciitis with eosinophilia
• Scleredema of Buschke

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Nail fold capillary microscopy—drop out is most significant finding.
• CBC
• Creatinine
• Urinalysis (albuminuria, microscopic hematuria)
• Antinuclear antibodies (ANA): positive in >90% of patients
• Anti–Scl-70 (anti-topoisomerase [ATA]) antibody is highly specific for systemic disease and confers a higher risk of interstitial lung disease (ILD).
• Anticentromere antibody usually associated with CREST variant
• Chest radiograph
  – Diffuse reticular pattern
  – Bilateral basilar pulmonary fibrosis
• Hand radiograph
  – Soft tissue atrophy and acroosteolysis
  – Can see overlap syndromes such as rheumatoid arthritis
  – SC calcinosis
Follow-Up Tests & Special Considerations

- Pulmonary function tests (PFTs)
  - Decreased maximum breathing capacity
  - Increased residual volume
  - Diffusion defect
- Antibodies to U3-RNP—higher risk for scleroderma-associated pulmonary hypertension
- Anti–PM-Scl antibodies (for myositis) (2)[B]
- Anti-RNA polymerase III—higher risk for diffuse cutaneous involvement and renal crisis (3)[A]
- ECG (low voltage): possible nonspecific abnormalities, arrhythmia, and conduction defects
- Echocardiography: pulmonary hypertension or cardiomyopathy
- Nail fold capillary loop abnormalities
- Upper GI
  - Distal esophageal dilatation
  - Atonic esophagus
  - Esophageal dysmotility
  - Duodenal diverticula
- Barium enema
  - Colonic diverticula
  - Megacolon
- High-resolution CT scan for detecting alveolitis, which has a ground-glass appearance or fibrosis predominant in bilateral lower lobes

Diagnostic Procedures/Other

- Skin biopsy
  - Compact collagen fibers in the reticular dermis and hyalinization and fibrosis of arterioles
  - Thinning of epidermis, with loss of rete pegs, and atrophy of dermal appendages
  - Accumulation of mononuclear cells is also seen.
- Right-sided heart catheterization: Pulmonary hypertension is an ominous prognostic feature.

Test Interpretation

- Skin
  - Edema, fibrosis, or atrophy (late stage)
  - Lymphocytic infiltrate around sweat glands
  - Loss of capillaries
  - Endothelial proliferation
  - Hair follicle atrophy
- Synovium
  - Pannus formation
  - Fibrin deposits in tendons
- Kidney
  - Small kidneys
  - Intimal proliferation in interlobular arteries
- Heart
  - Endocardial thickening
  - Myocardial interstitial fibrosis
  - Ischemic band necrosis
- Enlarged heart
- Cardiac hypertrophy
- Pulmonary hypertension

**Lung**
- Interstitial pneumonitis
- Cyst formation
- Interstitial fibrosis
- Bronchiectasis

**Esophagus**
- Esophageal atrophy
- Fibrosis

---

**TREATMENT**

**GENERAL MEASURES**

- Treatment is symptomatic and supportive.
- Esophageal dilation may be used for strictures.
- Avoid cold; dress appropriately in layers for the weather; be wary of air conditioning.
- Avoid smoking (crucial).
- Avoid fingersticks (e.g., blood tests).
- Elevate the head of the bed during sleep to help relieve GI symptoms.
- Use softening lotions, ointments, and bath oils to help prevent dryness and cracking of skin.
- Dialysis may be necessary in renal crisis.

**MEDICATION**

**First Line**

- ACE inhibitors (ACEIs): for preservation of renal blood flow and for treatment of hypertensive renal crisis
- Corticosteroids: for disabling myositis, pulmonary alveolitis, or mixed connective tissue disease (not recommended in high doses due to increased incidence of renal failure)
- NSAIDs: for joint or tendon symptoms; caution with long-term concurrent use with ACEIs (potential renal complications)
- Antibiotics: for secondary infections in bowel and active skin infections
- Antacids, proton pump inhibitors: for gastric reflux
- Metoclopramide: for intestinal dysfunction
- Hydrophilic skin ointments: for skin therapy
- Topical clindamycin, erythromycin, or silver sulfadiazine, and PDE5 inhibitors for prevention of recurrent infectious cutaneous ulcers

Consider immunosuppressives for treatment of life-threatening or potentially crippling scleroderma or interstitial pneumonitis such as cyclophosphamide for ILD (4)[B].

Nitrates, dihydropyridine calcium-channel blockers, PDE5 antagonists, and fluoxetine for Raynaud phenomenon (5)[A]

Avoidance of caffeine, nicotine, and sympathomimetics may ease Raynaud symptoms.

PDE5 antagonists (e.g., sildenafil), prostanoids, and endothelin-1 antagonists are changing the management of pulmonary hypertension (6).

Alveolitis: immunosuppressants and alkylating agents (e.g., cyclophosphamide)
ADDITIONAL THERAPIES

- Anti–TNF-α therapy: Preliminary suggestion is that this may reduce joint symptoms and disability in inflammatory arthritis, but small sample sizes and observational biases lend to the need for further well-designed, adequately powered, longitudinal clinical trials.
- Physical therapy to maintain function and promote strength
- Heat therapy to relieve joint stiffness

SURGERY/OTHER PROCEDURES

- Some success with gastroplasty for correction of GERD
- Limited role for sympathectomy for Raynaud phenomenon
- Lung transplantation for pulmonary hypertension and ILD
- Hematopoietic stem cell transplantation for selected patients with rapidly progressive SSc (5)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitor every 3 to 6 months for end organ and skin involvement and medications. Provide encouragement.
- Echocardiology and PFTs yearly

DIET

Drink plenty of fluids with meals.

PATIENT EDUCATION

- Stay as active as possible, but avoid fatigue.
- Printed patient information available from the Scleroderma Federation, 1725 York Avenue, No. 29F, New York, NY 10128; (212) 427-7040
- Advise the patient to report any abnormal bruising or nonhealing abrasions.
- Assist the patient about smoking cessation, if needed.

PROGNOSIS

- Possible improvement but incurable
- Prognosis is poor if cardiac, pulmonary, or renal manifestations present early.

COMPLICATIONS

- Renal failure
- Respiratory failure
- Flexion contractures
- Disability
- Esophageal dysmotility
- Reflux esophagitis
- Arrhythmia
- Megacolon
- Pneumatosis intestinalis
- Obstructive bowel
- Cardiomyopathy
Pulmonary hypertension
Possible association with lung and other cancers
Death

REFERENCES

ADDITIONAL READING

SEE ALSO

Morphea

CODES

ICD10
- M34.9 Systemic sclerosis, unspecified
- M34.1 CR(E)ST syndrome
- L94.0 Localized scleroderma [morphea]

CLINICAL PEARLS
- Raynaud phenomenon is frequently the initial complaint.
- Skin thickening, “puffy hands,” and GERD are often noted early in disease.
- Patients must be followed proactively for development of pulmonary hypertension or ILD.
SEASONAL AFFECTIVE DISORDER
Christopher White, MD, JD, MHA

BASICS

DESCRIPTION
- Seasonal affective disorder (SAD) is a heterogeneous mood disorder with depressive episodes usually occurring in winter months, with full remissions in the spring and summer.
- Ranges from a milder form (winter blues) to a seriously disabling illness
- Must separate out patients with other mood disorders (such as major depressive disorder and bipolar affective disorder) whose symptoms persist during spring and summer months

EPIDEMIOLOGY

Incidence
- Affects up to 500,000 people every winter
- Up to 30% of patients visiting a primary care physician (PCP) during winter may report winter depressive symptoms.
- Predominant age: occurs at any age; peaks in 20s and 30s
- Predominant sex: female > male (3:1)

Prevalence
- 1–9% of the general population
- 10–20% of patients identified as having mood symptoms will have a seasonal component.

ETIOLOGY AND PATHOPHYSIOLOGY

The major theories currently involve the interplay of phase-shifted circadian rhythms, genetic vulnerability, and serotonin dysregulation.
- Melatonin produced by the pineal gland at increased levels in the dark has been linked to depressive symptoms; light therapy on the retina acts to inhibit melatonin secretion.
- Serotonin dysregulation, because it is secreted less during winter months, must be present for light therapy to work, and treatment with SSRIs appears to reverse SAD symptoms.
- Decreased levels of vitamin D, often occurring during low-light winter months, may be associated with depressive episodes in some individuals experiencing SAD symptoms.

Genetics
- Some twin studies and a preliminary study on GPR50 melatonin receptor variants have suggested a genetic component.
- Recent studies indicate an association with the melanopsin gene (OPN4).
- Increased incidence of depression, ADHD, and alcoholism in close relatives

RISK FACTORS
- Most common during months of January and February: Patients frequently visit PCP during winter months complaining of recurrent flu, chronic fatigue, and unexplained weight gain.
- Working in a building without windows or other environment without exposure to sunlight

GENERAL PREVENTION
- Consider use of light therapy at start of winter (if prior episodes begin in October), increase
time outside during daylight, or move to a more southern location.

- Bupropion (Wellbutrin) is the only FDA-approved antidepressant for the prevention of SAD.

**COMMONLY ASSOCIATED CONDITIONS**

Some individuals with SAD have a weakened immune system and may be more vulnerable to infections.

**DIAGNOSIS**

- Carefully document the presence or absence of prior manic episodes.
- Screen for the existence of any suicidal ideation and safety risk factors.
- Remission of symptoms during spring and summer
- Symptoms have occurred for the past 2 years.
- Seasonal episodes associated with winter months substantially outnumber any nonseasonal depressive episodes.
- Under DSM-5, SAD is denoted by adding the “with seasonal pattern” specifier to a diagnosis of major depressive disorder, recurrent.

**HISTORY**

- Symptoms of depression meeting the criteria for major depressive disorder are the following:
  - Sleep disturbance: either too much or too little
  - Lack of interest in life and absence of pleasure from hobbies/activities
  - Guilt: feelings of guilt or worthlessness
  - Energy: fatigue or constantly feeling tired
  - Concentration: difficulty with concentration and memory
  - Appetite: changes in appetite and weight
  - Psychomotor retardation: Patients feel slowed down with decreased activity.
  - Suicidal thoughts: Patients report thoughts of suicide.
- In SAD, hypersomnia, hyperphagia (craving for carbohydrates and sweets), and weight gain usually predominate. Despite sleeping more, patients report daytime sleepiness and fatigue. Cravings may lead to binge eating and weight gains >20 lb.
- Obtain collateral history if patient is unable to provide insight into the seasonal component.

**PHYSICAL EXAM**

Use exam to exclude other organic causes for symptoms. Focal neurologic deficits, signs of endocrine dysfunction, or stigmata of substance abuse should prompt further testing.

**DIFFERENTIAL DIAGNOSIS**

- Similar to that of major depression, meaning that organic causes of low energy and fatigue, such as hypothyroidism, anemia, and mononucleosis (or other viral syndromes), need to be considered.
- Other mood disorders without a seasonal component such as major depression, bipolar disorder, adjustment disorder, or dysthymia
- Symptoms should not be better accounted for by seasonal psychosocial stressors, which often accompany the winter holiday seasons.
- Substance use disorders

**DIAGNOSTIC TESTS & INTERPRETATION**
- Thyroid-stimulating hormone to rule out hypothyroidism
- CBC to rule out anemia
- Rule out electrolyte and glucose dysregulation.
- 25-OH vitamin D level
- Pregnancy test for women of childbearing potential
- Urine toxicology screen if substance use is a concern
- Imaging is not useful unless focal neurologic finding or looking to exclude an organic cause.

### TREATMENT

#### MEDICATION

Lack of evidence to determine whether light therapy or medication should be the first-line agent. Both supported by the literature and in some studies have equal efficacy. Medications have more side effects. Adherence to both remains a critical issue. The ultimate choice depends on the acuity of the patient and the comfort level of the prescribing clinician with each treatment modality (1)[B].

- SSRIs such as sertraline (Zoloft), paroxetine (Paxil), fluoxetine (Prozac), citalopram (Celexa), and escitalopram (Lexapro) in their traditional antidepressant doses (2)[B]
- Bupropion (Wellbutrin) is the only antidepressant currently approved by the FDA for the prevention of SAD (3)[B].

#### ISSUES FOR REFERRAL

- Patients with a history of ocular disease should be referred for an ophthalmologic exam before phototherapy and for serial monitoring.
- Patients who fail to respond or who develop manic symptoms or suicidal ideation once treatment is initiated should be considered for psychiatric referral.

#### ADDITIONAL THERAPIES

- Phototherapy using special light sources has been shown to be effective in 60–90% of patients, often providing relief with a few sessions (2,4)[B].

  Variables that can regulate effect are the following:
  - Light intensity: Although the minimum light source intensity is under investigation, at least 2,500 lux is suggested (domestic lights emit, on average, 200 to 500 lux). There is good evidence for 10,000 lux as the recommended source (2)[B].
  - Treatment duration: Exposure time varies based on intensity of light source, with daily sessions of 30 minutes to a few hours.
  - Time of treatment: Most patients respond better by using the light therapy early in the morning.
  - Color of light source: Emerging data suggest that shorter sessions of lower intensity light-emitting diodes enriched in the blue spectrum have equal efficacy to the traditional white light treatment (5)[B].

- Light box is placed on table several feet away, and the light is allowed to shine onto the patient’s eyes (sunglasses should be avoided). Ensure that the light box has an ultraviolet filter.
- Most common side effects are eye strain and headache. Insomnia can result if the light box is used too late in the day. Light boxes also can precipitate mania in some patients.
- Dawn simulation machines gradually increase illumination while the patient sleeps, simulating
sunrise while using a significantly less intense light source.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Work to reduce stress levels through meditation, progressive relaxation exercises, and/or lifestyle modification.
- The potential role of vitamin D supplementation is under investigation. Currently, there is a lack of consistent research to satisfactorily demonstrate that treatment improves SAD symptoms. Reported doses vary widely but typically are between 400 and 800 IU/day [6][B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

If the patient develops suicidal ideation as part of his or her depression or mania after treatment is initiated.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Regular monitoring by PCP or psychiatrist for response to treatment; patients may become manic when treated with SSRIs or light therapy.

**Patient Monitoring**

Patients should be seen in the outpatient clinic weekly to biweekly when initiating light or pharmacotherapy to monitor treatment results, side effects, and any increased suicidal thoughts if using SSRIs.

**DIET**

No specific diet modification needed.

**PATIENT EDUCATION**

- Increase time outdoors during daylight.
- Rearrange home or work environment to get more direct sunlight through windows.

**PROGNOSIS**

Symptoms, if untreated, generally remit within 5 months with exposure to spring light, only to return in subsequent winters. If treated, patients usually respond within 3 to 6 weeks.

**COMPLICATIONS**

Development of suicidal ideation and mania are two outcomes the clinician needs to monitor.

CLINICAL PEARLS

- SAD is a subtype of major depressive disorder. Once the patient has a diagnosed mood disorder, such as depression or bipolar, ask whether the symptoms vary in a seasonal pattern to qualify for the diagnosis of SAD. Generally, these patients will report sleeping too much, eating too much (especially carbs and sweets), and gaining weight during winter months.
- Ensure that the symptoms are not due to an organic process or better explained by substance use.
- Guidelines suggest using SSRIs first if the patient is more acute or has contraindications to light therapy or the clinician is not comfortable with light therapy.
- Light therapy boxes are available from numerous online suppliers but are not extensively regulated; practitioners should take care to ensure that patients are using devices from reputable suppliers.
- If using SSRIs, recent studies indicate that some patients may begin to experience increased suicidal thoughts on therapy; these patients need to be monitored closely as outpatients every 1 to 2 weeks. Patients on light therapy also should be monitored closely initially in order to
adjust treatment. Once stabilized, both groups of patients can be seen every 4 to 8 weeks during the winter months.
SEIZURE DISORDER, ABSENCE
Amy Gallardo, FNP-C • Anthony Russo, MD

BASICS
DESCRIPTION
• Absence seizures are a type of generalized nonmotor seizure characterized by a brief lapse of awareness.
• Absence seizure types according to the International League Against Epilepsy (ILAE) 2017 classification include:
  – Typical
    o Abrupt onset and offset of behavioral arrest, loss of awareness, and blank staring, sometimes with eyelid movements, eye opening, or oral automatisms (e.g., lip smacking)
    o Typically occurs at 3 Hz
    o Lasts 5 to 30 seconds
    o Immediate return to normal consciousness with no aura or postictal phase
    o Associated with childhood absence epilepsy (CAE), juvenile absence epilepsy (JAE), and juvenile myoclonic epilepsy (JME)
  – Atypical
    o Onset and offset less abrupt than typical absence seizures and often with loss of muscle tone or subtle myoclonic jerks
    o Typically occurs at <2.5 Hz
    o Lasts 10 to 45 seconds
    o Impairment of consciousness often incomplete with continued purposeful activity, albeit done more slowly
    o Brief postictal confusion can sometimes occur.
    o Associated with Lennox-Gastaut syndrome and Dravet syndrome
  – Myoclonic
    o Abrupt onset and offset of staring and loss of awareness with continuous rhythmic jerks of shoulders, arms, legs, head, or perioral muscles
    o Typically occurs at 2.5 to 4.5 Hz
    o Lasts 10 to 60 seconds
    o Impairment of consciousness varies from complete loss of awareness to retained awareness.
    o Associated with epilepsy with myoclonic absences, learning disability, and behavioral problems
  – Eyelid myoclonia
